SAN FRANCISCO, Oct. 15—Several errors having been found in the official records of last week's two-day motor truck contest in this city, a new and revised statement has just been issued by Walter C. Manuel, the official A. A. A. referee. With the tangle straightened out the position of several trucks in the contest is changed.

In the 1,500-pound division the Reo is declared the winner on its economy record of $.0809 per ton-mile, with the Buick second at $.0861 and the White third at $.0869. The Reo suffered 86 points road penalties while the Buick and White were perfect in this regard.

In the 1-ton class the Franklin won at a cost of $.0795 per ton-mile, with the Grabowsky second, at $.0812.

The Autocar is declared winner in the fifth division with a cost per ton-mile of $.0507 and the White second at $.0537. A Federal, with 550 points road penalties, is third at $.0847.

The biggest surprise came in the 5,001- to 7,000-pound class, in which the Reliance is declared the winner with a cost per ton-mile of $.0358. The Packard is second at $.0369. The White is third at $.0376 and the Kelly (originally declared the winner) now comes fourth at $.0388 per ton-mile. The Gramm is fifth at $.04 and the Pope-Hartford, which suffered 90 points road penalties, is sixth at $.0429.

In the big division for cars between 7,001 and 10,000 pounds the White No. 19 is declared the winner. Its cost per ton-mile was $.0228, a record which also secured for it the Grand Prize.

The White No. 23 was second at $.0230; the Pierce-Arrow third at $.02336 and the Speedwell fourth at $.0271. The Lewis, a California made truck, which suffered 50 points road penalties came in fifth at $.0298 per ton-mile. The table follows.

Racer Sues for Prize Money

OAKLAND, CAL., Oct. 15—Almost every automobile dealer in Oakland has been joined in the suit brought by Earl de Vore, a racing driver, who wants prize money that failed to materialize after the race was won and the shouting over.

De Vore claims he was urged by the Oakland Dealers' Association to enter the contest. He drove a Pope-Hartford and won his race. When he claimed the $200 prize, however, no money was forthcoming. Now, besides suing the association, he has entered claim against every one of the dealers who are members of the organization.

Fatal Accident Mars Races at Sioux City

SIOUX CITY, IA., Oct. 23—"Billy" Pearce, the well-known driver, was killed when his Colby car dashed through the fence, on a trial run on the Sioux City track, the day before the races. Thursday afternoon Pearce was trying out the track, and made the first mile in 1:01. He was increasing his speed, and it is said that he attempted to make a "hairpin" turn, on the first curve from the grandstand, running close to the outside fence, and turning square. The car swerved and dashed through the inside fence. The machine was not badly injured.

Pearce had made fast time on this track the year before, and among other trophies, his Fal car captured the G. & J. trophy at the Indianapolis races in 1909. At the Omaha races two weeks ago he carried off practically all the honors with his Colby car.

On account of Pearce's death, one race, a ten-mile race for cars of Class B-3 B, was called off. Summary:

25-Mile Race, for Stock Cars

Pos.	Car	Driver	Time
1	Buick	John Sparling	25:27
2	Paige-Detroit	J. W. Shrunk	
3	Chalmers	H. A. Wetmore	
4	Moon	Philip Wells	
5	Reo	Walter Gnehm	
6	Ford	Jim Ralston	

Australian Pursuit Race for Class D Cars

Won by Buick, driven by Sparling; the Moon, Wells, second.

10-Mile Event for Class C-2 C

1	Paige	Shrunk	10:32
2	Reo	Gnehm	
3	Ford	Ralston	
4	Chalmers	Wetmore	

10 Miles for Class B-4 B Stock Cars

1	Buick	Sparling	10:42
2	Jackson	Harry Woodruff	
3	Cutting	Delaney	

The 50-mile race was the big event the second day. The Buick led for some distance, but was stopped by officials to change tires. The Paige then led but was also compelled to stop. Summary:

50-Mile Free-for-All

Pos.	Car	Driver	Time
1	Chalmers	Wetmore	55:57
2	Abbott-Detroit	Marvel	
3	Buick	Sparling	
4	Paige	Shrunk	

Class C-2 C, 10 Miles

1	Paige	Shrunk	11:04
2	Chalmers	Wetmore	
	Ford	Ralston	

Class C-4 C, 10 Miles

1	Buick	Sparling	10:17
2	Jacksen	Young	
3	Moon	Wells	

How New York Will Regulate Garages

Text of Proposed Ordinance Which Is Under Discussion

The new garage law adopted by New York City tersely defines the status of the garage and limits quantity of inflammable oils and other chemicals that may be stored. Permits issued for special garage locations. Fire Commissioner's certificate necessary for storage tanks. Minute details on gasoline handling. Repair shops to be regulated. Storage and sale of kerosene oil arranged for. Signs prohibiting smoking must be displayed.

CHAPTER XXI

DEFINITION—*By the term garage is meant a building, shed or enclosure, or any portion thereof, in which a motor vehicle is kept, housed or stored.*

Sec. 1. It shall be unlawful for any person to store, house or keep within the City of New York any motor vehicle containing volatile inflammable oil except in a building, shed or enclosure for which a garage permit has been issued by the Fire Commissioner.

Sec. 2. An application for a garage permit shall give in detail the following information:

(a) Name of applicant.
(b) Location of premises.
(c) Nature of construction of building.
(d) Description and maximum number of motor vehicles to be stored therein.
(e) Maximum quantity of volatile inflammable oils to be stored or kept at one time.
(f) Maximum quantity of calcium carbide to be stored or kept therein at one time.

Sec. 3. When an application is made for a garage permit wherein more than one motor vehicle is to be stored, housed or kept, or where volatile inflammable oil is to be stored or kept, the application must be accompanied with a detailed plan of the premises, drawn to a scale of not less than one-fourth of an inch to the foot.

Sec. 4. No garage permit to store more than one motor vehicle, or for the storage of any volatile inflammable oil, shall be issued for any building:

(a) Which is situated within fifty feet of the nearest wall of any building occupied as a school, theater, or other place of public amusement or assembly.
(b) Which is occupied wholly or in part as a tenement house, hotel, workshop or factory.
(c) Which is a frame or wooden building.
(d) Which is not lighted solely by electricity.
(e) Where drugs, cigars, cigarettes or tobaccos are kept for sale.
(f) Where paints, varnishes or lacquers are manufactured, stored or kept.
(g) Where dry goods of any kind or other materials of a highly combustible nature are manufactured, stored or kept.
(h) Where matches, rosin, turpentine, hemp, cotton, guncotton, smokeless powder, blasting powder, or any other explosives are stored or kept.

Sec. 5. The application and plan mentioned in sections 2 and 3 of this chapter shall be referred to the Municipal Explosives Commission; and upon the recommendation of said Commission the Fire Commissioner may issue a permit.

Sec. 6. A permit may be issued for a garage on premises on which there is a dwelling occupied by the applicant or by his employee, provided that the entrance to the living apartments shall not be through the garage; and provided further that not more than three motor vehicles may be kept or stored in such garage, and that none of them shall be let out for hire.

Sec. 7. A permit may be issued for a garage in a building occupied as a dwelling by either the applicant and one other tenant or by the applicant's employee and one other tenant, provided that not more than two floors or stories above said garage shall be occupied or used as living apartments, such floors being separated from the garage by unpierced fire-proof walls and floors; and provided further that not more than four motor vehicles may be stored in such garage and that none of them shall be let out for hire.

Sec. 8. No volatile inflammable oil except that contained in the motor vehicles may be stored in any garage for which a permit has been issued under sections 6 and 7 of this chapter, unless the building in which such garage is situated is of fireproof construction throughout.

Sec. 9. All garages wherein volatile inflammable oils are stored shall be continuously under the care and supervision of one or more persons each holding a certificate of fitness as a superintendent or manager of a garage. The number of persons required to hold certificates of fitness in each case shall be determined by the Fire Commissioner and shall be stated in the permit.

Sec. 10. No garage permit authorizing the storage of volatile inflammable oils shall be issued for any premises which are not equipped with an oil separator, trap or other contrivance attached to the house drain for the purpose of preventing volatile inflammable oils from flowing into the sewer.

Sec. 11. No garage permit authorizing the storage of volatile inflammable oils shall be issued for any premises which are not equipped with a tank or tanks of sufficient capacity for the storage of such oils except as otherwise provided in this chapter.

Sec. 12. No garage permit authorizing the storage of volatile inflammable oils shall be issued for any premises which are not equipped with one or more portable tanks for the transfer of such oils from the storage tank to the motor vehicles. The number of such portable tanks shall in each case be determined by the Fire Commissioner and stated in the permit.

Sec. 13. No garage permit authorizing the storage of volatile inflammable oils shall be issued for any premises which are not equipped with a pump or other apparatus for drawing off such oils from the storage tank.

Sec. 14. No storage tank, portable tank, oil separator, pump or other apparatus shall be installed in a garage unless a certificate of approval for the same shall have been issued by the Fire Commissioner.

Sec. 15. Applications for certificates of approval for any of the articles mentioned in the preceding section shall be made to the Fire Commissioner, and shall have attached thereto complete working drawings for such articles.

Sec. 16. Each storage tank shall be constructed of steel at least one-quarter of an inch in thickness; shall have a capacity of not more than two hundred and seventy-five gallons, and shall, under test, stand a hydrostatic pressure of at least two hundred and fifty pounds to the square inch.

Sec. 17. Each storage tank shall be coated on the outside with tar or other rust-resisting material, and shall be embedded in and surrounded by at least twenty-four inches of clean sharp sand, well stamped into place.

Sec. 18. Each storage tank shall be so set that the top or highest point thereof shall be at least four feet below the level of the lowest cellar floor of any building within a radius of twenty-five feet from the tank.

Sec. 19. No storage tank shall be placed under the sidewalk or under the front area of any garage.

equipped with a filling pipe, a drawing-off pipe and a vent pipe; provided, however, that no storage tank installed in a garage as a part of an hydraulic storage system shall be required to have a vent pipe. All pipes shall be of galvanized wrought iron and shall have malleable iron fittings. All screw joints must be made with litharge and glycerine.

Sec. 21. The filling pipe must be at least two inches in diameter, and shall be laid at a descending grade from the sidewalks in front of the garage to the tank.

Sec. 22. The intake of the filling pipe shall be located in a heavy cast-iron box, which shall be sunk flush with the sidewalk at the curb level and fitted with a heavy metal cover which shall be kept locked when the filling pipe is not in use.

Sec. 23. The filling pipe shall be closed at the intake by a cock or valve fitted with a coupling for attaching to the hose of a barrel wagon, and with a screw cap to close the opening when not in use.

Sec. 24. Each filling pipe shall be provided with a screen made of two thicknesses of 20-mesh brass wire gauze, placed not more than two inches below the filling cock or valve.

Sec. 25. The vent pipe shall be at least one inch in diameter, and shall run from the tank to the outer air at least ten feet above the roof of any building within a radius of twenty-five feet from the garage, and at least twenty feet from any window in adjoining buildings, and shall be well braced in position.

Sec. 26. The vent pipe shall be capped with a double goose-neck and provided with two screens made of two thicknesses of 20-mesh brass wire gauze and placed, one at or near the tank connection, and the other just below the goose-neck.

Sec. 27. The drawing-off pipe shall be not more than two and one-half inches in diameter in its largest dimension and shall be fitted with as many outlets as may be required, but not to exceed one for each floor of the garage.

Sec. 28. Each drawing-off pipe shall be encased in and surrounded by either six inches of Portland cement concrete or eight inches of brick masonry throughout its entire length.

Sec. 29. Each outlet for a drawing-off pipe shall be located in a separate compartment built upon suitable foundations having no opening except into the garage, and having walls, floors and roof constructed of Portland cement concrete at least six inches thick, or of brick masonry at least eight inches thick, the brick to be laid in and surrounded by Portland cement mortar. Each compartment shall be fitted with a self-closing iron door which shall always be kept locked except when oil is being drawn.

Sec. 30. No compartment wherein there is an outlet for drawing off volatile inflammable oil shall be situated in the area between the building and the sidewalk, or under the sidewalk, or within the stoop line; nor shall such compartment have a greater floor area than twenty-five square feet for one outlet and fifteen square feet for each additional outlet.

Sec. 31. The floor of each compartment wherein an outlet for drawing off volatile inflammable oils is located shall be graded to a common center and connected with a drainage pipe running into the oil separator.

Sec. 32. Each pump for delivering volatile inflammable oils shall be located in the compartment provided for in section 29 of this chapter, and shall be equipped with a shut-off valve with ground key on nozzle and with a check valve between the pump and the nozzle.

Sec. 33. Each compartment wherein an outlet for the drawing off of volatile inflammable oils is located shall be equipped with a ventilating flue, constructed of brick or concrete lined with tile pipe at least eight inches square inside measurement, and extending from the floor of the compartment at a point opposite the door to at least six feet above the highest point of the roof of the garage or any adjoining building within a radius of twenty-five feet of the garage.

Sec. 34. Each ventilating flue shall have an opening into the compartment 4 by 6 inches in area and three inches above the floor.

Sec. 35. Each flue shall be capped with a double goose-neck eight inches square, made of at least 18-gauge galvanized iron, with all openings covered with 20-mesh brass wire screens.

Sec. 36. The provisions of sections 29, 30, 31, 32, 33, 34 and 35 of this chapter shall not be held to apply to garages located in buildings that are of fireproof construction throughout. In such buildings no separate drawing-off compartment shall be required.

Sec. 37. It shall be unlawful for any person to deliver volatile inflammable oils from a storage tank to a motor vehicle by means of a portable tank or directly through the outlet of the drawing-off pipe.

Sec. 38. Each portable tank shall be of a capacity not exceeding fifty gallons, and mounted on a suitable iron frame with rubber-tired wheels. The volatile inflammable oil contained in the tank shall be discharged only by means of a pump through a hose not exceeding eight feet in length having a shut-off valve close to its outlet.

Sec. 39. No pump or outlet for the delivery of volatile inflammable oils in a garage shall be allowed on any floor below the street level; and it shall be unlawful for any person to deliver a volatile inflammable oil to the tank of any motor vehicle while on the floor of a garage below the street level.

Sec. 40. Each portable tank used in a garage shall bear a number corresponding to the floor of the garage on which it is used; and it shall be unlawful for any person to remove a portable tank containing volatile inflammable oil from one floor to another floor in a garage.

Sec. 41. Each wagon delivering volatile inflammable oils to a garage shall be equipped with a metallic hose having an automatic shut-off valve at the coupling next to the barrel containing such oils.

Sec. 42. No barrel containing volatile inflammable oil shall be taken off the wagon, but the oil shall be delivered directly to the storage tank of the garage through the filling pipe by means of a hose coupled to the barrel containing the oil and connected to the intake provided for in section 22 of this chapter.

Sec. 43. No wagon or other vehicle engaged in the delivery of volatile inflammable oils shall be admitted to or taken within a garage or any portion thereof.

Sec. 44. It shall be unlawful for any person to deliver to or receive within a garage any volatile inflammable oil in barrels or other receptacles, or to keep or store in a garage any barrel or other receptacle from which volatile inflammable oil has been drawn.

Sec. 45. Each oil separator installed in a garage shall be connected to the house drain and so arranged so as to separate all oils from the drainage of the garage. The drainage from water closets in garages shall not be emptied into the separator, but shall be discharged directly into the sewer.

Sec. 46. It shall be unlawful for any person to throw or discharge any volatile inflammable oil into the urinals or water closets of a garage.

Sec. 47. The oil receptacle of an oil separator shall not exceed fifty gallons in capacity, and shall be emptied as often as may be necessary to prevent the oil from overflowing; and such oils as are recovered from the separator must be removed from the garage within twenty-four hours after being taken from the separator.

Sec. 48. All volatile inflammable oils spilled in a garage must be recovered by sponging or swabbing, and poured into the drain leading to the oil separator.

Sec. 49. A garage shall not be artificially lighted except by electric lights having air-tight tubes or bulbs or globes encased in suitable wire cages, fitted with keyless sockets. All electric switches and plugs shall be placed at least four feet above the garage floor.

Sec. 50. No system of artificial lighting other than incandescent electric lights shall be installed in any garage unless a certificate of approval for such system shall have been issued by the Fire Commissioner.

Sec. 51. No stove, forge, torch, boiler, furnace, flame or fire; electric dynamo, motor hoist or other electric appliance which is likely to produce an exposed spark, shall be allowed in any garage or in any building wherein a garage is situated, unless that portion of such building is separated from the garage by unpierced fireproof walls and floors.

Sec. 52. No motor vehicle shall be stored or kept in a garage unless the tank of such motor vehicle is equipped with a safety or fusible plug for which a certificate of approval has been issued by the Fire Commissioner.

Sec. 53. All fires and lights in or upon a motor vehicle shall be extinguished before bringing it into a garage, and shall not be lighted while the motor vehicle remains in the garage.

Sec. 54. It shall be unlawful for any person to smoke or carry a lighted cigar, cigarette or pipe within a garage or any room or enclosed place in which volatile inflammable oil is kept. A notice bearing in large letters the words "SMOKING UNLAWFUL," together with a copy of this section in smaller letters, shall be displayed in one or more conspicuous places on each floor of a garage.

Sec. 55. It shall be unlawful for any person to use or handle volatile inflammable oils within a garage for any purpose other than that of filling the tank of a motor vehicle.

Sec. 56. Each garage shall be permanently equipped with fire buckets filled with sand and kept on each floor, for use in extinguishing fires. A quantity of sand shall also be kept upon each floor of a garage for absorbing waste oils. The quantity of sand and the number of buckets for each garage shall be designated by the Fire Commissioner and stated in the permit.

Sec. 57. Each floor of a garage shall be equipped with self-closing metal cans, and all inflammable waste material shall be kept therein.

Sec. 58. All calcium carbide stored in a garage shall be kept in water-tight metal containers with securely fastened covers, but the aggregate quantity kept on hand at any one time shall not exceed fifty pounds.

Sec. 59. A person who violates any of the provisions of this chapter is guilty of a misdemeanor.

Sec. 60. (Sec. 25. Chap. III). For a garage permit issued under sections 5 and 6 of Chapter XXI of these regulations, the applicant shall pay an annual fee of Five Dollars for each motor vehicle stored therein.

Sec. 61. (Sec. 26. Chap. III). For a garage permit allowing the storage of volatile inflammable oils, the applicant shall file a bond in a penal sum to be fixed by the Fire Commissioner, but in no case shall the amount thereof be less than Five Thousand Dollars, and shall pay an annual fee of Fifty Dollars for a single storage tank and Twenty-five Dollars for each additional storage tank installed in such garage.

CHAPTER XXII

MOTOR VEHICLE REPAIR SHOPS

Definition—By the term motor vehicle repair shop is meant, a building, shed or enclosure, or any portion thereof, wherein motor vehicles are repaired for hire or by hired employees.

Sec. 1. Except as provided in the following section, it shall be unlawful for any person to keep or maintain a motor vehicle repair shop within the City of New York without a permit from the Fire Commissioner.

Sec. 2. A person holding a permit issued in conformity with the provisions of chapter XXI of these regulations shall not be required to obtain a permit under this chapter.

Sec. 3. Applications for permits to maintain motor vehicle repair shops shall give in detail the following information:

(a) Name of applicant.
(b) Location of premises where the repair shop is to be maintained.
(c) Nature of construction of building.

Sec. 4. It shall be unlawful for any person to store or keep in a motor vehicle repair shop any volatile inflammable oil or calcium carbide.

Sec. 5. It shall be unlawful for any person to introduce or receive into a motor vehicle repair shop any motor vehicle containing a volatile inflammable oil, unless the building or that portion of the building occupied as such repair shop is of fireproof construction throughout.

Sec. 6. A person who violates any of the provisions of this chapter is guilty of a misdemeanor.

Sec. 7. (Sec. 28, Chap. III). For a permit allowing the operation of a Motor Vehicle Repair Shop, the applicant shall pay an annual fee of Twenty-five Dollars.

CHAPTER XXIII

MANUFACTURE, TRANSPORTATION, STORAGE AND SALE OF PETROLEUM, AND OTHER MINERAL OILS

Sec. 1. Except as otherwise provided in these regulations, it shall be unlawful for any person to manufacture, refine, transport, store, sell or deliver, any petroleum, or the liquid products thereof or of coal tar or shale oil, without a permit from the Fire Commissioner.

Sec. 2. Applications for permits to manufacture, refine or distill petroleum, coal tar or shale oil, within the City of New York, shall give in detail the following information:

(a) Name and office address of the applicant.
(b) Location of plant.
(c) Manner and place of storing raw material.
(d) Manner and place of storing finished product.
(e) Nature of finished product.
(f) Maximum capacity of the plant in daily output.
(g) Name of each person designated by the applicant to have charge or supervision of the whole or a part of the plant.
(h) Operation necessary for the manufacture of the finished product.

Sec. 3. In connection with the application mentioned in the preceding section, the applicant shall file a plan, in duplicate, drawn to a scale of not less than one-sixteenth of an inch to the foot, showing clearly thereon the following information:

(a) Location of plant.
(b) Nature of construction and dimensions of each building, storage tank and supply pipe in the plant enclosure.
(c) Purpose for which each building is used.
(d) Description and maximum quantity of material to be stored in each storage tank or building.
(e) Maximum quantity of oil passing through each supply pipe per hour.
(f) Location of each building with reference to nearest buildings outside the enclosure on all sides.

Sec. 4. The provisions of sections 2 and 3 of this chapter shall apply only to plants for the manufacture, refining and distilling of petroleum now existing in the City of New York, and no permit shall hereafter be issued for the erection or operation of any new plant of a similar character.

Sec. 5. It shall be unlawful for any person to transport, deliver or receive within the City of New York any volatile inflammable oil in a receptacle other than a galvanized steel barrel equipped with a safety or fusible plug for which a certificate of approval has been issued by the Fire Commissioner.

Sec. 6. The provisions of the preceding section shall not apply to the transportation of volatile inflammable oils when contained in glass bottles of not more than four ounces capacity each and plainly marked on the outside "DANGEROUS: Keep from Flame"; nor shall the provisions of said section apply to the transportation of such oils in cans of a capacity not less than one nor more than five gallons, for delivery only to persons holding permits for the storage and sale at retail of such oils.

Sec. 7. It shall be unlawful for any person to sell or deliver within the City of New York any volatile inflammable oil in quantities greater than one gallon unless the purchaser or receiver thereof holds a permit issued by the Fire Commissioner in conformity with these regulations for the storage, sale or use of such oils.

Sec. 8. Each vender of volatile inflammable oils shall render to the Fire Commissioner on the first business day of each month a written statement, verified as to its correctness by an affidavit, describing the deliveries of volatile inflammable oils in quantities greater than one gallon made within the City of New York during the preceding month. Such statements shall be made upon forms furnished by the Fire Commissioner, and shall give in detail the following information:

(a) Date of delivery.
(b) Name of purchaser and number of his permit.
(c) Place of delivery.
(d) Quantity and kind of oil delivered.

Sec. 9. All cans used for the delivery of volatile inflammable oils shall be equipped with a metal seal so arranged that there shall be no outlet for the oil unless the seal is broken.

Sec. 10. No barrel, can, drum or package shall be used for the delivery of volatile inflammable oil unless a certificate of approval therefor has been issued by the Fire Commissioner.

Sec. 11. Petroleum and all liquid products thereof and of coal tar and shale oil, except volatile inflammable oils, may be transported within the City of New York in the following containers:

(a) In tank cars or through supply pipes.
(b) In steel, iron or wooden barrels, of a capacity not exceeding fifty-five gallons each.
(c) In cans of a capacity not exceeding ten gallons each, made of galvanized iron or at least No. 24 B. & S. or I. C. charcoal tin or terne plate, and packed in substantial wooden cases.
(d) In cans, drums or packages not exceeding ten gallons capacity each, made of at least No. 25 B. W. G. tin or terne plate.

Sec. 12. It shall be unlawful for any person to carry or transport within the City of New York any petroleum or the liquid products thereof or of coal tar or shale oil, in a tank wagon unless a certificate of approval has been issued therefor by the Fire Commissioner.

Sec. 13. The tank of a wagon used for the transportation of petroleum or the liquid products thereof or of coal tar or shale oil, shall be constructed of iron or steel not less than one-eighth of an inch in thickness for the top plates and three-sixteenths of an inch in thickness for the bottom plates, and equipped with faucets which shall be kept locked when not in use. The capacity of a tank wagon shall not exceed thirty barrels of fifty-five gallons each.

Sec. 14. All tank wagons shall have painted on both sides thereof, in conspicuous letters not less than two inches high, the name of the person, corporation or association operating the same, and the number of the certificate of approval.

Sec. 15. It shall be unlawful for any person to drive or have charge of a tank wagon in transit within the City of New York without having obtained a certificate of fitness from the Fire Commissioner.

Sec. 16. It shall be unlawful for any person to transport or carry in or upon a wagon or other vehicle, except a tank wagon, any petroleum or the liquid product thereof or of coal tar or shale oil, in quantities aggregating more than twenty-five barrels of fifty-five gallons each.

Sec. 17. Permits for the storage of a petroleum or the liquid products thereof or of coal tar or shale oil may be issued by the Fire Commissioner upon written application giving in detail the following information:
(a) Name and office address of the applicant.
(b) Location of plant.
(c) Nature and maximum quantity of oil to be stored.
(d) Name of each person designated by the applicant to have charge or supervision of the plant, and the number of his certificate of fitness.
Sec. 18. In connection with the application mentioned in the preceding section the applicant shall file a plan, in duplicate, drawn to a scale of not less than one-sixteenth of an inch to the foot, showing clearly thereon the following information:
(a) Location of plant.
(b) Nature of construction and capacity of each tank and building and the location thereof with reference to the nearest buildings not forming part of the plant.
Sec. 19. It shall be unlawful for any person to store or keep in a storage plant within the City of New York any petroleum or the liquid product thereof, or of coal tar or shale oil, in quantities in excess of the following:
(a) Volatile inflammable oils: fifty steel barrels of fifty-five gallons each.
(b) Other oils that do not emit in inflammable vapor below 100 degrees Fahrenheit; if in barrels, three hundred barrels of fifty-five gallons each; if in cans, a quantity not exceeding one thousand gallons; if in storage tanks, a quantity not exceeding fifty thousand gallons.
Sec. 20. Except as provided in the following section, all storage tanks shall be embedded in soft earth so that the tops thereof shall be at least two feet below the street level.
Sec. 21. For the purpose of facilitating the filling of tank wagons, there may be installed in a storage plant not more than four tanks, elevated on brick piers, and having an aggregate capacity of not more than five thousand five hundred gallons, for the storage of oils that do not emit an inflammable vapor below 100 degrees Fahrenheit. Such oils must be returned to the storage tanks underground each day at sunset.
Sec. 22. It shall be unlawful for any person to connect any part of a storage plant with a sewer, or to allow any of the liquid products of petroleum to escape into any sewer within the City of New York.
Sec. 23. It shall be unlawful for any person to keep or maintain a plant for the storage of petroleum, or any of the liquid products thereof or of coal tar or shale oil, unless such plant is continuously in charge of a person holding a certificate of fitness issued by the Fire Commissioner.
Sec. 24. No permit shall be issued for the storage of petroleum or any of the liquid products thereof, or of coal tar or shale oil, in any building which is occupied wholly or in part as a tenement house or dwelling, or in any building having more than one floor below the street level; nor for the storage of any such oils upon any floor of any building above the ground floor.
Sec. 25. Whenever the physical conditions along the shore front in the City of New York are such as to make it impracticable to place underground a storage tank for the storage of volatile inflammable oils to be delivered to launches and other vessels for generating motive power, the Fire Commissioner may, upon the recommendation of the Municipal Explosives Commission, issue a permit for a tank not to exced two thousand five hundred gallons capacity, to be placed and maintained in such manner and under such conditions as the Municipal Explosives Commission shall prescribe, which conditions shall be clearly stated in the permit.
Sec. 26. For the purpose of filling the tanks of launches and other vessels using a volatile inflammable oil for generating motive power, such oils shall be transferred to the tank of such vessels directly by a pipe from a storage tank, and not otherwise.
Sec. 27. It shall be unlawful for any person to smoke or to carry a lighted cigar, cigarette or pipe within a storage plant where petroleum, or any of the liquid products thereof or of coal tar or shale oil, is stored or kept; and a sign bearing, in large letters, the words "SMOKING UNLAWFUL," together with a copy of this section in smaller letters, shall be posted in one or more conspicuous places in such plant.
Sec. 28. A person who violates any of the provisions of this chapter is guilty of a misdemeanor.
Sec. 29. (Sec. 31, Chap III.) For a permit allowing the storage of petroleum, or any of the liquid products thereof, and of coal tar and shale oil, in a storage plant as provided for in section 17 of chapter XXIII of these regulations, the applicant shall pay an annual fee of One Hundred Dollars.

CHAPTER XXIV

STORAGE AND SALE AT RETAIL OF VOLATILE INFLAMMABLE OILS

Definition—By the term volatile inflammable oils is meant, any oil or liquid that will generate an inflammable vapor at a temperature below 100 degrees Fahrenheit when tested either in the open air or in the closed pyrometer of Giuseppe Tagliabue.
Sec. 1. Permits for the storage and sale at retail of volatile inflammable oils may be issued by the Fire Commissioner upon written application giving in detail the following information:
(a) Name and office address of the applicant.
(b) Location of the premises in which the oils are to be stored.
(c) Nature of construction of the building.
(d) Purpose for which the building is used.
(e) Nature of the business in which the applicant is engaged in such building.
Sec. 2. No permit shall be issued for the storage or sale of volatile inflammable oils within the City of New York in any building:
(a) Which is occupied wholly or in part as a tenement house, dwelling, school or place of public assembly or amusement.
(b) Where any explosives are stored or kept for sale.
(c) Where dry goods of any kind are manufactured, stored or kept for sale.
(d) Which is lighted by any artificial means other than electricity.
Sec. 3. No volatile inflammable oil shall be stored in a building for which a permit has been issued in accordance with the provisions of this chapter in quantities aggregating more than fifty gallons.
Sec. 4. It shall be unlawful for any person to store, keep, sell or deliver any volatile inflammable oil except in original packages with the seal unbroken, or to open any such package within the premises covered by the permit, or to sell or deliver any volatile inflammable oil in a quantity less than one gallon.
Sec. 5. It shall be unlawful for any person to smoke or to carry a lighted cigar, cigarette or pipe within any premises covered by a permit issued in accordance with the provisions of this chapter; and a sign bearing, in large letters, the words "SMOKING UNLAWFUL," together with a copy of this section, in smaller letters, shall be posted in one or more conspicuous places in such premises.
Sec. 6. The floor of each store or premises covered by a permit issued in accordance with the provisions of this chapter, shall at all times be kept clean and free from all accumulation of waste paper and other inflammable material, and shall be provided with self-closing metal cans for keeping sawdust or cotton waste used for cleaning purposes, and also with a number of buckets filled with sand for use in exteinguishing fires; the number of buckets to be so kept shall be determined by the Fire Commissioner and shall be stated in the permit.
Sec. 7. A person who violates any of the provisions of this chapter is guilty of a misdemeanor.
Sec. 8. (Sec. 34, Chap. III). For a permit allowing the storage and sale at retail of volatile inflammable oils, as provided for in chapter XXIV of these regulations, the applicant shall pay an annual fee of Ten Dollars.

CHAPTER XXV

STORAGE AND SALE AT RETAIL OF KEROSENE OIL

Definition—By the term kerosene or kerosene oil is meant, any liquid product of petroleum commonly used for illuminating purposes which does not emit an inflammable vapor below the temperature of 100 degree Fahrenheit when tested either in the open air or in the closed pyrometer of Giuseppe Tagliabue.
Sec. 1. It shall be unlawful for any person to store, keep or sell within the City of New York any kerosene or other mineral oil to be used for lighting purposes in quantities greater than five gallons without a permit from the Fire Commissioner.
Sec. 2. Permits for the storage and sale of kerosene and other mineral oils used for lighting purposes may be issued by the Fire Commissioner upon application giving in detail the following information:
(a) Name and address of the applicant;
(b) Location of premises;
(c) Character of construction of building;
(d) Purpose for which the building is used and number of families residing therein, if any;
(e) Nature of the business in which the applicant is engaged in such building.
Sec. 3. No permit shall be issued for the storage and sale of kerosene or other mineral oil used for lighting purposes in quantities greater than seventy gallons in any building occupied wholly or in part as a tenement house.
Sec. 4. No permit shall be issued for the storage or sale of kerosene or other mineral oil used for lighting purposes in any building in quantities greater than two hundred and seventy-five gallons.
Sec. 5. It shall be unlawful for any person to store or keep any kerosene or other mineral oil used for lighting purposes except in the original package, or in a tank, can or container for which a certificate of approval has been issued by the Fire Commissioner.
Sec. 6. Certificates of approval for cans, tanks and other containers for the storage of kerosene or other mineral oils used for lighting purposes may be issued by the Fire Commissioner upon the recommendation of the Municipal Explosives Commission.
Sec. 7. It shall be unlawful for any person to sell or offer for sale any kerosene or other mineral oil used for lighting purposes which will emit an inflammable vapor at a temperature lower than 100 degrees Fahrenheit, when tested either in the open air or in the closed pyrometer of Giuseppe Tagliabue.
Sec. 8. All kerosene barrels, cans and containers shall be removed from the premises immediately after being emptied.
Sec. 9. A person who violates any of the provisions of this chapter is guilty of a misdemeanor.
Sec. 10. (Sec. 35, Chap. III). For a permit allowing the storage and sale of kerosene or other mineral oils to be used for lighting purposes, as provided for in chapter XXV of these regulations, the applicant shall pay an annual fee of Ten Dollars.

Preparing for Richmond's Good Roads Meeting

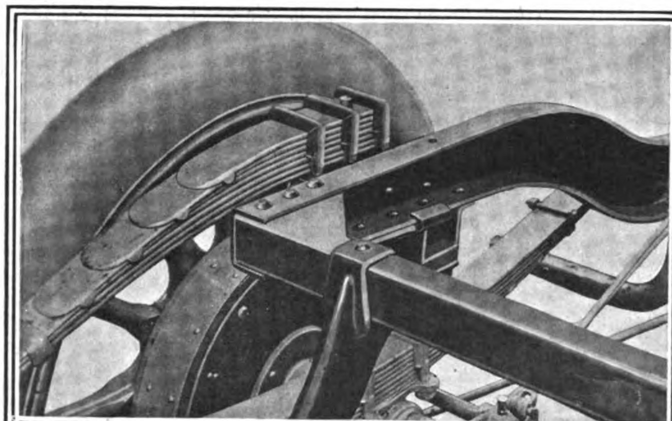
RICHMOND, VA., Oct. 23—Novel, indeed, are the suggestions made by the executive committee of the Richmond Automobile Club for decorated automobiles during the convention of the National Highway Association, the week of November 20.

It is proposed to make the auto parade historical, depicting the men who settled Jamestown, the red men who watched them, the men of the time of Bacon's Rebellion, Governor Berkeley, Patrick Henry, John Marshall and "Light Horse" Harry Lee. The idea would be to put these historic men in automobiles and take them over the road to Petersburg and let them see the scene of the battle of the Crater, and other historical points.

President Taft has given every assurance that he will be here to attend the big highway meeting.

Seventeen Entries in Chicago Run

CHICAGO, Oct. 23—Seventeen cars are entered in the fifth annual reliability run of the Chicago Motor Club, which starts Friday for a 1,300-mile trip through five States. In the touring car class there are entered two Molines, two Halladays, two Staver-Chicagos and one each of the Case, Lion, Abbott-Detroit and Oldsmobile. The roadster division includes two Molines, two Velies, and one each of the Oakland, Bergdoll and Grout. The itinerary of the tour calls for night stops at Indianapolis, Louisville, Cincinnati, Columbus, Detroit and Grand Rapids. Sunday will be spent in Louisville. In addition to the contestants there will be several official cars—a Halladay pilot, a Packard pacemaker, a National press car, a Midand checker's car and a Haynes technical committee car.



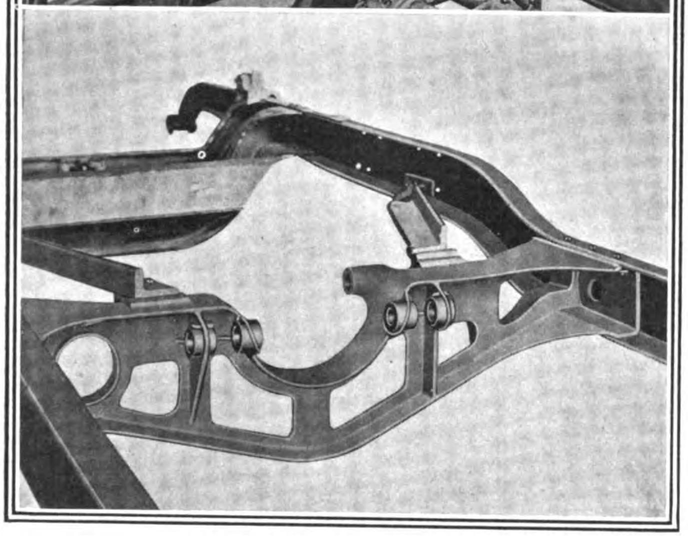


Fig. 5—Showing the attachment of rear springs on all Overland chassis for 1912 models

Fig. 6—The celebrated malleable iron cross member in the frames of all Overland cars

In the motor the thermo-syphon water piping has been increased in capacity from 25 to 75 per cent. in the different models. These pipes are aluminum castings. As in all thermo-syphon motors the radiator has to be well elevated above the cylinder heads. The aluminum crankcase is a two-part casting, the upper carrying the five crankshaft bearings, the lower constituting an oil reservoir and basin. In models 58 and 59 a mechanical oiler is used and consequently the lower part of the crankcase serves merely as a basin; whereas in 60 and 61 a circulating oiling system is used and the base of the cage contains a sump or oil reservoir beneath the crankcase proper. In the circulating system the oil is delivered from the gear pump through a pipe to the middle of the crankcase, where it is poured against a divider of inverted V form cast on the inside of the case. The oil falling onto the apex of this divider is sent half to the front of the case and half to the rear. This supplies two splash levels and the oil splashed by the four connecting rods lubricates the crankshaft and camshaft bearings and also the cylinder walls, wrist pins and piston rings.

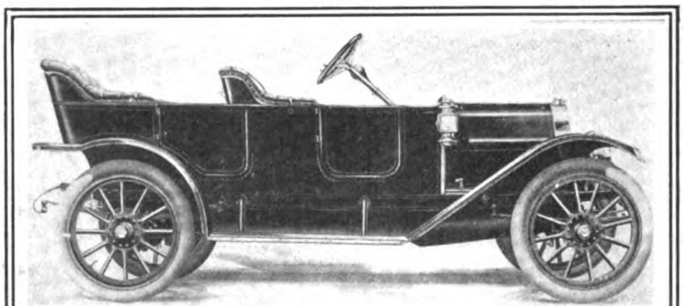
On models 58 and 59 the mechanical oiler is carried over the intake water pipe on the right side of the motor and has six leads, four to the cylinders, one to the rear crankcase compartment and one to the timing gear compartment at the front end of the motor.

A most important motor improvement on some of the models is the enclosing of the valve spring, Fig. 2, on the model 51. The cover for each valve spring is made up of semi-cylindrical parts held in place by two circular springs which surround them as clamps. A further improvement, one not shown in the illustration, is the method employed of preventing oil from leaking out by way of the valve stem. A real packing-box system is used. The bottom of the valve-stem bushing, which sets into the cylinder casting, is formed with an annular recess and into this packing is fitted, a steel washer being used below the packing to retain it in position. The washer is in turn retained in place by a small spring similar to the valve spring, and located around the valve stem and inside of the valve spring. Provision is also made to prevent the valve-lifter rods from acting as plunger pumps and lifting oil which is splashed on their lower ends within the crankcase. The guide for the lifter is made with two vertical slots from top to bottom, in conjunction with an annular space at the top of the slots, so that the oil, which works up by the pumping action, flows off of the lifter into the slot and then flows down the slots into the crankcase, thus not only conserving the oil supply but aiding in keeping the motor clean—a potent factor in the modern car.

The Overland company has been a consistent exponent of the cone clutch, and continues its use. It is equipped with a clutch brake, which bears upon the cone face when disengaged to prevent its spinning, thus slowing it down and making gear shifting possible without grinding of the teeth of the meshing gears. Another clutch feature is the limited plunger action of the six radial plungers, which are regularly spaced around the cone periphery and bear outward beneath the asbestos facing. Each plunger stem is carried in a bracket attached to the cone. In the stem, near the clutch center, is a restricting pin, which, when the plunger presses outward 3-32 inch, bears against the bracket, stopping its movement. This prevents too quick engagement, or gripping when throwing the clutch in. The cone-clutch part is self-centering with the flywheel through the use of a three-arm spider, which bears upon a semi-spherical support, the semi-sphere allowing of the cone finding its own center.

The dual ignition system is used in all four chassis: On 58 and 59 the Splitdorf outfit is employed; on 60 it is the Remy, and on 61 use is made of the Bosch. The carbureter is the new Schebler model L. The carbureter is carried very low, the top of it being on a level with the lower half of the crankcase. Gravity feed is used.

One of the Overland frame features is the use of a malleable-iron cross-member, Fig. 6. This takes the place of forty-seven original pieces in the frame. It serves, in a word, to support the clutch and brake-operating parts and on its rear face are two eye-holes to which the arms of the yoke on the front end of the torsion tube, containing the propeller shaft, are attached.



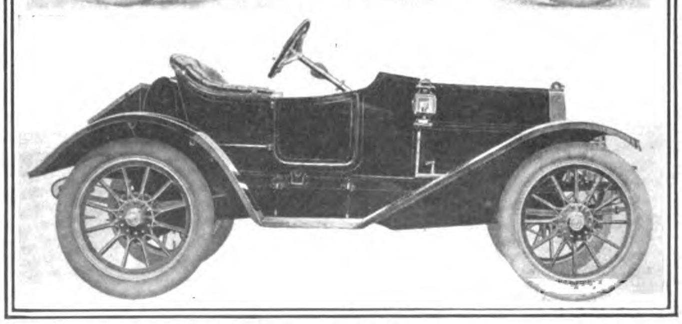


Fig. 7—Overland Model 59 touring car with 106-inch wheelbase and 32 by 3.5-inch tires

Fig. 8—Overland Model 58 roadster with 96-inch wheelbase and 32 by 3.5-inch tires

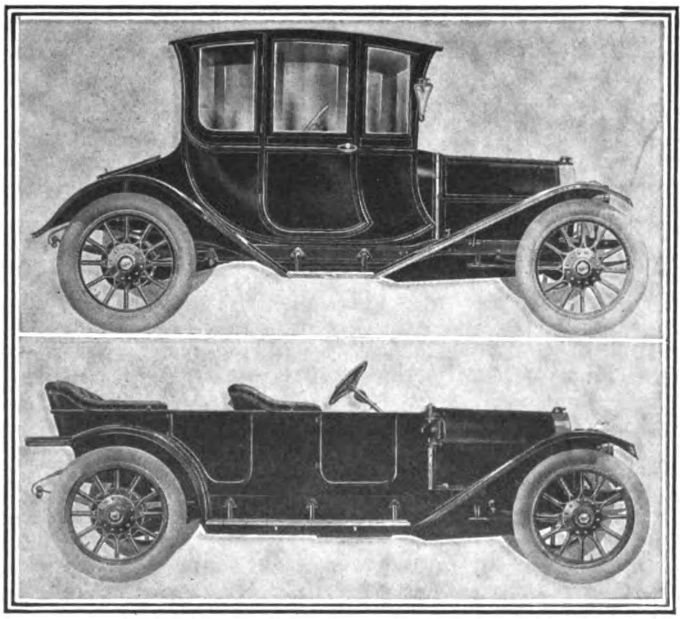

Fig. 9—Overland Model 61 coupé with 118-inch wheelbase and 34 by 4-inch tires

Fig. 10—Model 61 Overland touring car with 118-inch wheelbase and 34 by 4-inch tires

On all models the brakes are of the same design as used this year; that is, internal and external on the rear wheel drums. Fig. 11 shows the method of adjustment. On the brake rocker shaft is a sector, with a slot which has a toothed or serrated margin. The brake connection arm takes a pin with nut on the opposite end. By loosening the nut this arm can be set in any position in the slot in the sector and held there. This gives every possibility of range. By adding the springs all rattling of the external band has been eliminated. These are new. Quick disengagement of the expanding brakes is insured by the springs. The drum sizes are 10 x 2 inches on 58 and 59; 12 x 2 on 60, and 14 x 2 1-2 on model 61.

On all models semi-elliptic front springs are used. On 58 the rear springs are elliptics, but on the 59, 60 and 61 a three-quarter elliptic is used. Fig. 5 shows the bracket for attaching these springs to the frame. The spring is held by three clips and the lower part of the bracket is turned over or clinched on the lower lip of the frame. The heavy corner gusset reinforces the frame at this point.

Where selective gearshifts are used—and they are employed in all but one model—the three-speed set is made use of. On models 60 and 61 chrome vanadium steel gears are used and F & S annular ball bearings fitted. On models 60 and 61 an improvement in direct drive is the use of an internal gear into which meshes the sliding unit, in place of the dental-face teeth for locking the gears formerly used and still continued on model 59. Shifting is decidedly easier with the internal-gear scheme.

The precautions taken by the Overland company to prevent leaking of oil from the motor parts are also in evidence in the rear axle. With rear axles the big problem is to keep the lubricant in the differential housing, where it is needed, and prevent its leaking out at the ends of the axle sleeves and getting on the brake drums as well as on the spokes of the wheels. In this work two systems are used, the simpler on models 58, 59 and 60, and a more elaborate one on model 61. On models 58, 59 and 60 a packing is held at each side of the differential in the axle sleeves. It is retained by a washer at each side of it. The outer washer bears against a shoulder formed by the end of the axle sleeve and the inner washer is pressed against the packing by a coil spring. This holds the packing firmly in position.

In the model 61 a real stuffing-box scheme is made use of. A stuffing box threads into the axle sleeve and is anchored there. The axle driver shaft where it passes through the stuffing box is ground to give a non-leak fit.

The Overland model 61 has other special features as compared with models 58, 59 and 60. One of these is a new gearshift. The gearshift lever works in a single slot, which is a feature in fore-door bodies and especially so if the shift lever is placed in the center of the car for manipulation by the left hand. The lever has a ball end, which is really not on the lever but on the latch which works inside of it. The lower end of this latch works in two slots, one located above the other, with a crossway between them. The different speeds are obtained as follows: By pushing the lever forward without pressure downward on the ball gives reverse, and pulling the lever back without downward pressure gives low speed. To get second speed the lever is moved forward with downward pressure on the ball, and to get direct drive it is pulled backward with the downward pressure. On the models 58, 59 and 60 a side movement of the gearshift lever is necessary.

Increased Use of Aluminum

According to a recent article in the Franfurter *Zeitung*, the development of the aluminum industry has been unusually rapid, the world's production having risen from 11,500 metric tons in 1905 to 24,200 metric tons in 1909, and 34,000 metric tons in 1910. The distinctive feature about the aluminum trade is that it is in the hands of only 12 companies, of which five account for nine-tenths of the total output. The price of aluminum per kilo. (2.2 pounds) was $6.50 in 1890, 50 cents in 1900, 80 to 90 cents in 1905, 27 to 36 cents in 1909 and 27 to 38 cents in 1910.

The Automobile in Many Lands

Rubber Industry in the East Indies Is a Most Important One — Help Becoming Scarce — Emperor William Now Owns Thirty Automobiles—Mexican Rubber Prices—English Signal Regulations—Other News Items from Continental Districts

HERE are some new and interesting facts connected with the rubber plantation industry in the Malays. Contract laborers—Chinese coolies—on the rubber estates are a sturdy lot of men. A contract printed in English and Chinese, signed by the local representative of the Planter's Labor Bureau, is given to each man. The contract provides for eight hours' work per day, 24 working days per month and extra pay for overtime, monthly payment of wages due and free passage back to Hong Kong after the three years' contract shall expire.

There is wonderful activity in the rubber plantation industry all over the Malay States. Large areas of jungle lands are being cleared for plantation rubber growing. The forests, very dense, are being subjected to the same heroic treatment as is the case in Ceylon and British Guiana, where trees are being planted and cultured. The dense forests are being felled and the underbrush is burned away. Some of the men who realize the rapidly growing demand for paper argue that the wild rubber trees that are being cut down to make way for the plantation industry might be converted into pulp, instead of letting them go to waste. Everywhere in the southeast part of India interest in the new industry is taking on a marvellous impetus. Coolies are in great demand. The planters in the Malays claim that 15,000 coolies are needed to tap and collect the latex of 4,000,000 trees. The planters are beginning to wonder where they will be able to get a sufficient amount of coolies from when the rubber trees of the Malay Peninsula shall have increased to 45,000,000 in number. They are already casting eyes upon China in anticipation of the need of more coolies.

There is much to be done before the rubber is ready to ship from the Malays to London—the charge for which amounts to about $17 per ton. There is the sorting process, work which requires great care, on account of the various prices that attach to the various grades of rubber, mixed lots selling at a reduction over lots that have been sorted after a system. The thin, transparent sheets and crêpes of rubber are most in demand in the market. After the rubber is put into cases—which are made in Japan, of white wood—it is weighed, a full case containing about 110 pounds. It is then carried to the transportation companies for shipment to London.

The high charges of the London rubber market have had the effect of inducing the plantation-rubber cultivators and buyers of the Malay States to organize a Rubber Exchange in Singapore. This in order that they may avail themselves of the opportunity to purchase raw rubber direct at the place of production. They argue that with this plan in operation they will be able to operate against the London brokers and extend the rubber market. The planters declare that up to the present time they have been absolutely at the mercy of the brokers and that for this reason they wish to have the business transacted near to the base of supply. Singapore being the center of the rubber-producing belt, it offers every advantage as a place of sale.

One firm in Singapore disburses $5,000,000 worth of raw rubber annually. A member of the firm is authority for the statement that by establishing an exchange a large portion of the para rubber output of the plantations would be marketed there, including Borneo, Malaysia, Sumatra and Java, and for the reason that the planter would be able to obtain the best prices. The services of the local middle-man would be less expensive, and at the same time more effective, than those of the broker thousands of miles away. The Exchange would be under obligation to prove that prices would be fair, made by free competition of the members to buy and sell the product entrusted to them. The Exchange would serve as a general storage plant, as well as a meeting place of members, and the business would be handled by a staff of experienced men.

The total amount of cultivated rubber exported from the Federated Malay States and Ceylon during the last seven years was 26,854,842 pounds.

Except in the case of re-exports from England or France, it is out of the question to buy American-made tires in Rio de Janeiro. The automobile accessories imported into Brazil yearly amount to $150,000, and yet the United States gets only $12,000 worth of this trade. Such accessories are sold there almost exclusively by agents representing European automobile houses. Another disadvantage which the American manufacturers of rubber tires encounter is the fact that the automobile trade is monopolized by European houses.

Rubber seed has become a valuable commercial factor in China, where it is proving a fine food for cattle. It is also an effective fertilizer. The seeds yield a clear oil, not inferior to linseed oil.

The new motor-car system of taxes went into force in Sheffield on the first day of September, 1910. Licenses are issued upon the basis of horsepower units, and they are apt to make cars an expensive luxury—one which none but the rich or the very extravagent could afford to carry even if so disposed. The new tax rate is from $4.86 for a motor-bicycle to $204.39 for a car above 60 horsepower. Many of the larger types of touring cars are being offered for sale at a sacrifice. The demand for cars above 20 horsepower is limited. The most popular cars in and about Sheffield are 15-horsepower machines. On cars of these dimensions a duty of $19.47 is levied.

The gauge of automobiles in Nuremberg and vicinity is from 4 feet and 1 inch to 6 feet and 1 inch, the size of the car governing the gauge. This is wider than the standard gauge of other vehicles, which is from 3 feet and 7 inches to 3 feet and 8 inches.

There are now about fifty automobiles in Yarmouth, Nova Scotia. This number includes twelve new machines purchased during the year ending in October, 1910. Of the half-hundred machines, thirty-four were manufactured in America. During the Summer half a dozen Canadian-made cars were brought to Yarmouth by cottagers.

Emperor William of Germany has just purchased four more new types of automobiles, thus augmenting his motor car fleet to thirty and again emphasizing his stand as an enthusiastic motorist. The majority of his machines are of German and French make. Six of these cars are utilized as luggage vans. The Kaiser keeps five of his automobiles at Corfu. No other person is permitted to possess a horn like that used on His Majesty's motor cars, the type of horn being that of a peculiar fanfare. When in commission the car bears the Imperial Standard flag, which flies beside the chauffeur by day. This ensign is replaced at night by an illuminated glass shield, revealing the Standard in regulation colors.

English law makes it compulsory upon automobilists to "carry a bell or other instrument" on motor cars. To this end the Local Government Board says that the signal "shall be used whenever necessary." This rather indefinite phrase is sometimes hard to interpret, for example, in a case of alleged neglect, when the matter is referred to a Magistrate. But the problem of the motor car horn, "hooter," siren or "road clearer" has become so great and the kinds of "instruments" in use so numerous that both motorists and pedestrians are in a muddle. To get out of it they are considering the feasibility of calling upon the respective Local Government Boards to agree upon some one definite type of horn to be used. Throughout the country English motorists seem to show a liking for a certain type of bugle, which contains ten notes, comprising the diatonic scale of the key of G, with F sharp and an extra A added.

France has just introduced a new type of motor truck. It is equipped with a tilting platform, about thirteen feet in length, and a capstan. The truck has a capacity for carrying loads of great weight, which, by reason of platform and capstan, are handled both in the loading and unloading at a wonderful saving of hand labor. The platform is tilted over the rear axle, while the loading truck is run out upon the ground. After having loaded the goods upon the truck, the workmen draw the truck back upon the tilting frame by means of the capstan. The frame is then tilted back and locked in its place. Not only have manufacturing concerns and commercial houses adopted the truck, but the military authorities have put it into commission.

Eisenach, Arnstadt and Apolda, in Germany, each maintain extensive automobile manufacturing plants and the output of motor cars and accessories from these factories is growing at a tremendous rate. Naturally, the demand for tires keeps pace. The people residing in the Erfurt region, where the above-named towns are located, know very little about American-made tires, Germany having supplied the bulk up to the present time, although there is one Great Britain firm which keeps a supply of tires in a branch factory in Germany. Tires made in France also go well in this vicinity. Upon the whole, Germany is beginning to demand a higher grade of tire than formerly used. Upolda and Arnstadt manufacture tires principally for small motor cars, the price of which is about $1,000 or less. The Thuringia hill country in the Erfurt section affords some of the grandest roads in Germany. The great touring cars made in this locality comprise high power, with a relative light weight, the automobiles made here being especially designed with the view to hard climbing. Heavy tires that will stand up, endure the strain over the mountain highways and not skid are in demand. At the same time these machines must be built so as to resist snow and ice.

The fact that a uniformity of prices prevails in the case of German-made tires stimulates the supposition that this line of industry, as it is conducted in the German Empire, yields a fair amount of profit to the manufacturers.

The requirements of the metric system obtain in Germany, as they do in Great Britain. Some of the American manufacturers have shown a disposition not to conform to patterns of automobiles built for export to the requirements of the metric system. This has proven to the disadvantage of American trade in Germany, at least in the matter of fixtures and mechanical attachments.

Manufacturers of rubber tires in Germany carry on an extensive business not alone with small dealers in automobiles, but they sell direct to the motor car factories. The customary terms given by German manufacturers are thirty days, with 2 to 3 per cent. discount for cash.

Some of the German tire manufacturers give a guarantee on tires "for 10,000 miles, to be run within twelve months from the date of delivery," under conditions which restrict the heft of loads.

Although crude guayule (Mexican) rubber, which sold for a time at $1.25, has dropped to 60 cents the pound in gold recently, the production in the Torreon section of that country does not seem to have fallen off. The amount of the product shipped from Mexico between November 23 and December 14, 1910, is given as 1,474,000 pounds. New York received the greater portion of it. In addition to this output the State of Coahuila has been coming to the front with a product of guayule rubber which has yielded something like $450,000 per month. There is a concern in Mexico whose product is over 1,500,000 pounds per month. The promoters are endeavoring to build up a European trade, especially in Germany, France and England. A considerable amount of guayule rubber has already been shipped to these countries. Estimates showing the cost of manufacturing the crude rubber from the guayule shrub run all the way from 40 cents the pound down to ten cents the pound. A great many contracts were made in the beginning—some of these are still in force—for shrubs at from $25 to $30 Mexican money per ton. The price at which the shrub is purchased and the expense involved in delivering it to the factory have a great deal to do with the extent of the profit.

Harking Back a Decade

THE following extracts have been taken from the *Motor Review* of October 24, 1901:

Alexander Winton has accepted an invitation from the Detroit Driving Club to use the Detroit track in an attempt to regain the mile track record now held by Fournier, which was wrested from him a few days ago.

George V. Brower, Commissioner of Parks of New York, having given his formal approval to the use of the Coney Island boulevard on Saturday afternoon, November 16, from 1 o'clock until 5, The Long Island Automobile Club announces a series of races for gasoline and electric vehicles, the horsepower of the gasoline vehicles to range from 6 to 20 horsepower.

The first annual convention of the National Association of Automobile Manufacturers, for the discussion of trade topics, will be held in the assembly room of the Madison Square Garden during the week of the automobile show on the forenoons of Tuesday and Wednesday, November 5 and 6.

The Stearns Steam Carriage Company, Syracuse, N. Y., has completed a new style surrey which will be sent to New York to be exhibited at the Madison Square Garden show. The surrey has a boiler of 621 flues and engines of 12 horsepower.

The municipal council of New York City last week aimed a blow at automobiles and their drivers by passing a resolution to enforce the automobile laws now in existence to the end "that pedestrians on the streets, avenues and roadways of the parks and passengers in vehicles drawn by horses may be protected."

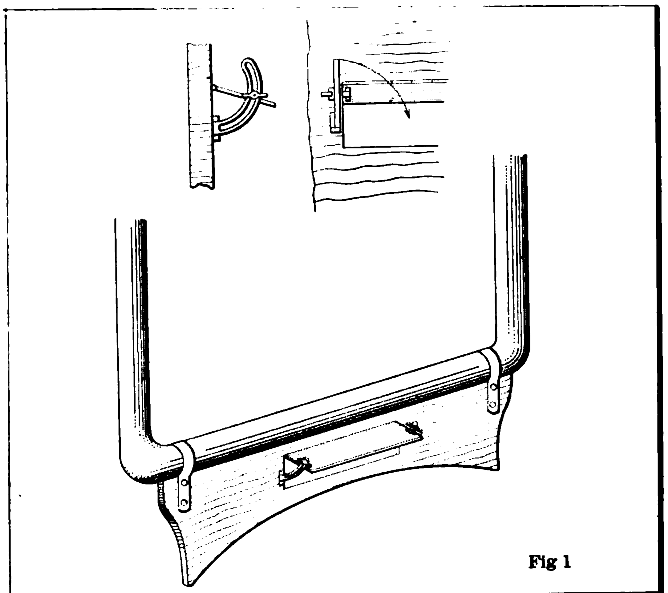
The Long Island Automobile Club conducted its initial run of the season on October 12, reaching Garden City at 2 p. m., where a special dinner awaited the chauffeurs, among whom were a number of women.

At the Providence, R. I., race meet it was expected that William K. Vanderbilt, Jr., with his Red Devil, and Foxhall Keene would be present, but owing to accidents to the machines they were unable to start. Arthur C. Bostwick with his 40-horsepower Winton went after records on the track. He soon had the spectators on tip-toe, and when it was announced that his first mile was made in 1:20¼ the people realized that there was speed in the machine. He made the 10 miles in 14:09¾.

Albert Champion, the noted French motor bicycle chauffeur, broke the world's records for 2, 3 and 4 miles in his race yesterday at Vailsburg, N. J. His times were: Two miles, 2:32; 3 miles, 3:50; 4 miles, 5:07, and 5 miles in 6:24.

Special Windshield Adaptations

By George J. Mercer



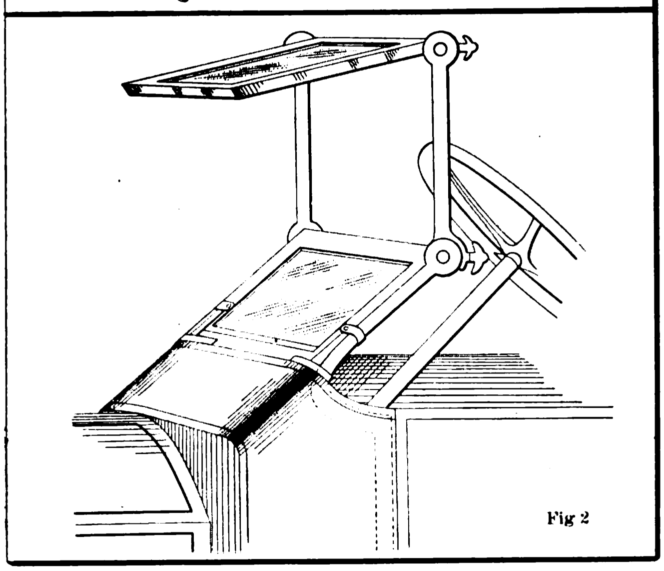


Fig. 1—Ventilator in base board of windshield for fore-door bodies
Fig. 2—The zigzag type of windshield with a leather filler board used

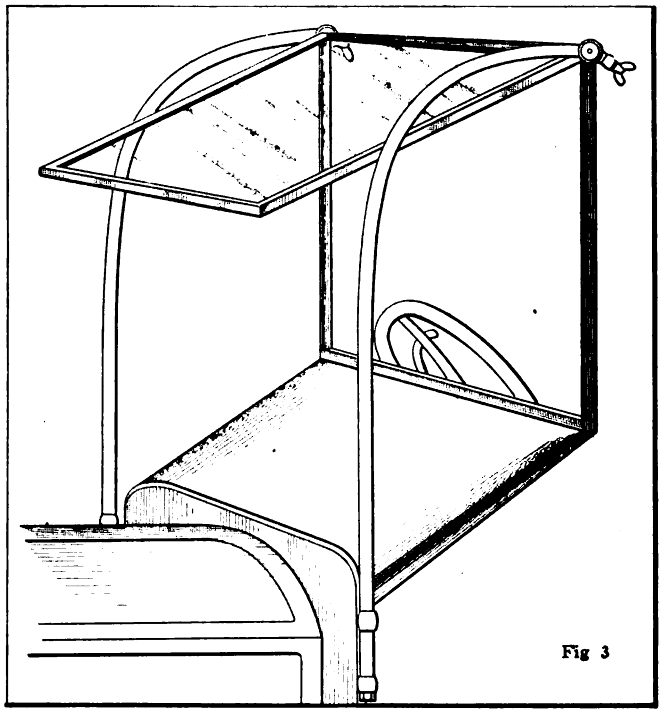

Fig. 3—A type of windshield that has many points of merit and is adaptable to many makes of cars on the market to-day

WITHOUT casting any discredit on the general appearance of the stock windshield, it is only reasonable to suppose that the shield made to conform to the body design, and built to the body as a part of it, will always carry a class that the ready-made product is lacking. It is quantity production against custom work and the price is according. Two illustrations, Figs. 3 and 4, show the altogetherness and harmony of design with the shield that is built on the body. The first design, Fig. 3, is used in this country on the Metallurgique car and it is the writer's impression that originally it came out on the English Daimler. It has merit both for its clean, symmetrical appearance as well as for its practical worth. It is made to conform to the design of the body front, the lower panel being a continuation of the cowl. The side rods are made to bend gracefully at the point of intersection with the cowl and are continued down and inside the body to form a supporting brace. The use of thumb nuts for fastening the swinging frame in position is shown on the illustration, but there is nothing to prevent the use of the automatic fastening and it would improve the shield, in fact it will soon be an impossibility to market a windshield that is not automatically fastened or made to operate with one hand.

In Fig. 4 is illustrated a shield made on the body. It is generally used on cars that have a very high cowl and where the owner is used to driving his car without an extension top. It can be tilted to any angle desired, the point of turning being at the bottom. The method of securing the braces to the body is shown and no stay rod is required at the front. It can be quickly removed from the body and the painted surface of the cowl is not left scarred as with the ordinary shield.

In Figs. 5, 6, 7 and 8 are four views of an English-made shield that does duty as a protection for the occupants of the rear seat of the car. A friend of the writer's assured him that this shield is as effective as its advocates claim, and his experience during a recent tour in England has made him a convert to its merit, especially for the between seasons when the air is raw and full of misty rain and the wheels are splashing the mud around and the wind is strong enough to carry it back to the tonneau of the car. Figs. 5, 6 and 8 show the plan, front and side views of the shield in position ready for use, and the arrows on the plan view show the means of folding the shield as well as indicating the means of extending or shifting the shield to best suit the needs of the user. It will be noted that there is great flexibility and the supports are made suitable to hold the shield rigid in a great variety of positions.

Fig. 7 indicates the position of the shield when folded and out of commission; it is made to lie closely to the rear of the front seat and there is in addition a shirt or cloth that hangs from the bottom of the frame. This cloth is long enough to almost touch the floor of the body and its object is to carry the protection afforded by the glass down to a point that the wind cannot enter, and when the glass frame is folded, as indicated in Fig. 8, this cloth can be made to fold over the same in the manner of a robe over the regulation robe rail. This cloth is not shown in the illustrations, as its effect would be to hide the more important parts of the shield.

The windshield until quite recently was listed as an extra by automobile manufacturers; that is, the stock car was a complete unit without it and the purchaser simply went a little deeper into his pocket if he thought a shield was essential to complete the outfit. Any doubt that existed in his mind as to the usefulness of a shield to him as a car user was generally founded on the fact that an inefficient article was being handed to the public at an inflated price because protection from the elements during certain months of the year must be provided for in some manner and a good windshield together with a good top will add the necessary comfort to the touring car and the runabout.

The commercial windshield on the market to-day is uniformly good and the variety is sufficiently large to suit nearly all requirements. The range of models extends from the simple shield, made of celluloid and pantasote, to the intricate shield with metal frame that can be made to assume a variety of different angles for deflecting the wind and the rain and that can also be made to collapse when not required. All these types of shields are common to car users and the description of such will be confined to the new feature that has lately been added to some models now on the market, that is, the ventilator that allows a current of air to be forced downward around the feet of those seated in the front of the car, the object being to offset the heated conditions that exists where fore-doors are used. Fig. 1 illustrates a standard make of shield with a ventilating door in the filler board. It is simply a metal door at the rear or inner side and is hinged at the top so it can be raised to permit the desired opening. The method of fastening is shown enlarged on the two sectional views at the top of the illustration. The slotted side arms are hinged at the bottom and when the door is closed these arms turn, as indicated by the arrow, and lie flat against the door, thus eliminating any projections from the board when the door is closed. The ventilator is still an experiment and the new shields coming out will no doubt present a variety of methods for accomplishing the desired result.

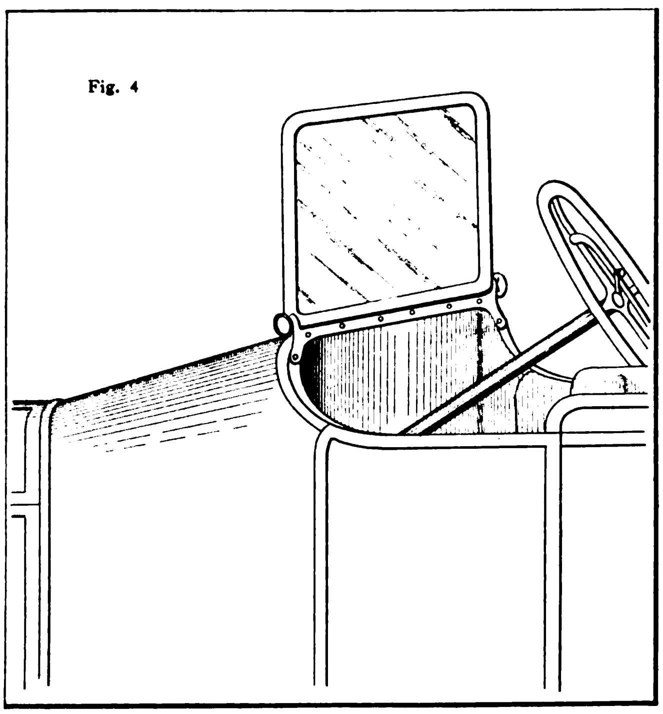

Fig. 4

Fig. 4—This illustration shows the results that can be obtained when a windshield is designed to especially suit the cowl dash and where its design harmonizes with the body lines of the car

Fig. 2 illustrates an essentially custom-made shield which can be made to fit any car easily and can be quickly removed or put on. It is easy to operate and is of the zigzag type without being as heavy as the usual shield of that style and the davits or side rods hold the frame firmly without the aid of stay rods. The lower panel is formed of leather and underneath this panel is a small rod from the dash to the frame to keep the latter from swinging forward. The leather will keep it from going backward. With this as with the zigzag shield the extension top can be made the minimum length forward over the driving seat. This shield is an American improved adaptation of the French model brought out a few years ago.

A Substitute for Platinum.—The great increase in the price of platinum, which is due to its scarcity, is resulting in a brisk demand for another rare metal which seems destined to take its place in many industrial applications. Palladium is the metal which possesses practically all the properties of platinum, being extremely hard, malleable, ductile and refractory to acids. Lately this substance has been obtained in relatively large quantities from the mining districts of Ontario, Canada. In the reduction of 200,000 tons of nickel ore 3,000 ounces of palladium is one of the valuable by-products.—*Riviste Mensile del Touring Club Italiano.*

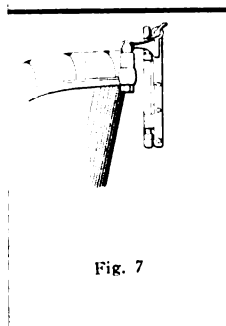

Fig. 7

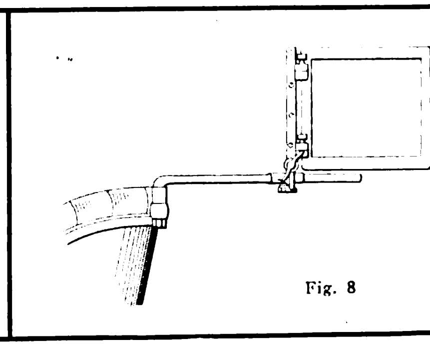

Fig. 8

Figs. 5, 6, 7 and 8 show different views of a type of windshield that can be carried on the back of the front seat of a car and used for the benefit of those in the tonneau. It has a wide field of uses and is a big comfort factor in a car

Digest of the Leading Foreign Papers

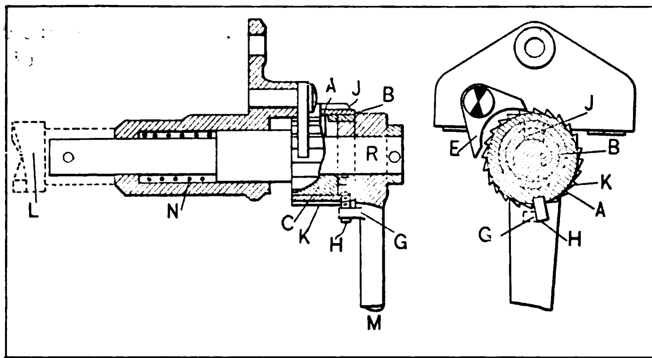

Fig. 1—The Clemencet safety starting crank

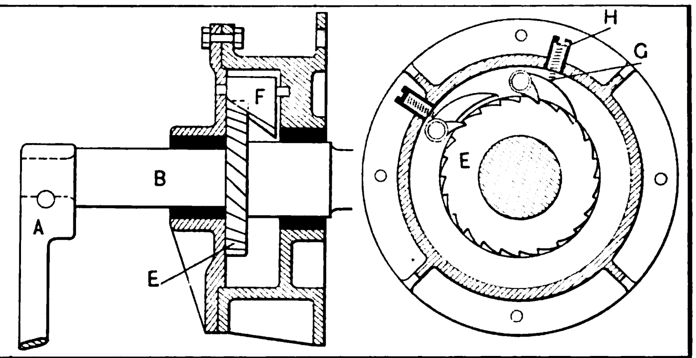

Fig. 2—The Castagnet safety starting crank

Safety Starting Cranks

FIFTY-EIGHT competitors responded to a call from the Industrial Society for the Prevention of Accidents in the Performance of Work when the latter planned an international test of devices for preventing all unintentional rotation of cranks for hoisting apparatus, such as cranes, winches and iron shutters for stores and warehouses, and particularly of starting cranks for automobiles. The object was to arrive at some standard construction by which accidents could be eliminated.

With regard to starting cranks it was required that the devices submitted for test should effect the immediate disengagement of the crank the moment the engine is either started in the normal direction or backfires. Only sixteen of the fifty-eight devices submitted met this condition and five out of these sixteen were for various reasons not presented at the trials, leaving only eleven to be compared and judged in practice. Some of these are herein partially described and illustrated.

The Clemencet safety crank, Fig. 1, is connected with the motorshaft by the customary jaw-clutch *L* and release spring *N*. The boss of the arm *M* is mounted idly upon the motorshaft extension *R*, but its axis is eccentric in relation to the axis of the shaft. On the arm there is a dog *G* to receive the thrust of disengagement. On the shaft *R* there is formed an integral collar *C* and a sleeve *A* mounted idly upon it with its cylindrical bore having the same eccentricity as that of the crank boss; its surface is provided with ratchet teeth *K* acting against the ratchet pawl *E*, so that the sleeve can turn only with the sun. This sleeve also carries the dog *H*, and when this dog *H* is nearly in contact with the dog *G* on the crankarm the center of the sleeve coincides with the center of the crank-boss and there is therefore room between the boss and the sleeve for the cylindrical ring *B*, which engages a slot in collar *C* by means of feather *J*. It must therefore rotate with collar *C* and shaft *R*. The operation is as follows: When the crankarm is turned for starting, dog *G* has no action on dog *H*. The eccentricity of the crank boss causes ring *B* to be gripped at once, carrying shaft *R* with it. And sleeve *A*, which can move in this direction, is also carried along, so that the whole system turns, dog *H* following dog *G* a few tenths of a millimeter behind. When the motor starts it does not take the crank with it, even if the customary release device fails to work; in fact, sleeve *A*, being free to rotate on collar *C* on shaft *R*, is held from movement in this direction by dog *H* abutting against dog *G*, and the ring *B* turns freely. If the motor backfires and turns the shaft *R* in the opposite direction the sleeve *A* is immediately stopped by the pawl *E*, the dog *G* is arrested by the dog *H* on the sleeve *A* and the ring *B* turns freely. The crank *M* is thus immediately released in either case when the motion is started from shaft *R*.

In the Castagnet safety crank, Fig. 2, the shaft *B* of the crank *A* carries a miter gear *E*. Two pawls *F* are so placed that one or the other can act at once, being spaced half a tooth apart in their action (though the illustration does not show it). They are applied against the miter gear by means of two helical springs *G* enclosed in the hollow adjustment screws *H*. The end of the crank spindle is provided with the usual clutch for gripping the motorshaft. In operation, if a reverse movement is produced, the crank tends at first to being carried along, but by reason of the angle of the pawls and the form of the gear teeth there is produced a longitudinal displacement of the spindle which causes the immediate disengagement of the clutch.

In the David safety crank, partially shown in the sectional view, Fig. 3, the crank hub is mounted upon the motorshaft *A* by means of a shoulder, a washer and a screw nut. The crankarm is secured to the collar *H* by a cotter. The collar *H* is externally concentric with the shaft *A*, while its bore is slightly eccentric. Two segments *K* and *K1* are placed in the space between the collar *H* and the shaft *A*. *K1* is secured to the collar *H* by screws, but *K* is notched to receive the rollers *g* and carries on one side the helical spring *r* and on the other the spring pawl *m*, which passes through a mortised hole in the collar *H* and engages a ratchet ring. When the crank is turned for starting the collar *H*, being eccentric, pinches segment *K* between itself and the shaft *A*, and the latter is rotated, while the pawl jumps from tooth to tooth. When the motor starts *K* is loosened and the crank is freed. If the motor is reversed the pawl immediately releases *K* and the crank is again free.—From *Bulletin Official*, August.

MOTOR POWERS FOR FARM AND SHOP—In reply to an inquiry, the following estimates are offered with regard to the work which may be entrusted to a gasoline motor, automobile or otherwise, particularly referring to work which in common European practice has usually been done by hand or horsepower.

The 4-horsepower motor can operate a threshing equipment (as distinguished from the portable threshing machine outfit), which has previously been worked with two horses. A 6-horsepower motor will take care of an equipment intended for four horses and with a capacity of about 150 bushels, in the case of wheat, per day. A 2-cylinder motor of 8-horsepowers will operate an equipment turning out 250 to 300 bushels of wheat per day and provided with a chaff-blower, a cleaner and a mechanical binder. With the same equipment a 10 to 12-horsepower motor will increase the output about 50 per cent.

Eight horsepowers will operate a circular saw cutting about 14 inches deep at the rate of 3 feet per minute. With a bandsaw the depth of the cut may be doubled.

The 4-horsepower motor will produce electric light for forty lamps of 16 candlepower each, at a cost of 5 cents per kilowatt (would be 2 cents per kilowatt at American prices for gasoline, provided the motor did not waste the difference by reason of poor design). An 8-horsepower motor is sufficient for running a moving-picture machine or to light a hall with a seating capacity for 300 to 500 persons.

The 4-horsepower motor will turn at the same time a cream separator, a churn, a feed-mixer, a kneeding machine and a washing machine on a farm of medium size. It can pump sufficient water in 1 hour from a depth of 90 feet for supplying a farm of 200 to 300 hectares (1 hectare equals 2.4 acres) with all the cattle usually kept on such an acreage. It is also amply large for doing all the power work in a small brewery and for running all the tools is a cabinet maker's shop. In a machine shop it will run at the same time two lathes, three drills, a milling machine and an emery grinder.

With 2 more horsepowers the farmer can run at the same time a chaff-cutter or a crusher and a root-cutter, a pump and a sheep-shearing machine.

A contractor with a motor of 4 to 6 horsepowers can transport by wagonets 2,000 cubic meters or yards of excavation material in 700 hours over a distance of 3 kilometers and with a difference in levels of 300 meters. He could take the same quantity a distance of 150 meters and to a level 15 meters in 35 hours.—From *La Vie Automobile,* Sept. 23.

How to Save Fuel—First of all give the carbureter plenty of air. In nine cases out of ten the mixture used is unnecessarily hot after the motor is once warmed. When running down hills, either take the clutch out and throttle the engine to dead slow, or shut the throttle off altogether and let the engine brake against the compression whenever possible. In this case there should be an air inlet upon the induction pipe, to be opened so as to prevent the formation of partial vacuums in the combustion chambers and the resulting flooding thereof with lubricating oil. Or else, the gear can be put into the neutral position and the engine stopped—that is if it starts easily off the switch on every downgrade. Much fuel may be saved by keeping the pace down to the most economical speed, which for ordinary cars is generally about 20 to 25 miles an hour on the top gear, as above this speed the wind resistance comes in as an important factor in adding to the work to be done by the engine and puts up the fuel consumption at once. Lastly, there must not be any racing of the engine up hills on any speed, and the engine must not be left working when any stop over half a minute is necessary. In a month's running of about 1,000 miles, the writer has been able to save about 9 gallons of gasoline, by following these precepts, making 17 1-2 miles per gallon instead of 15 miles, as by his previous driving practice.—From *The Car,* Sept. 27.

Mexican Rubber Industry Develops

Torreon, Mexico, Oct. 10—The industrial world may well be astounded at what has been accomplished in the development of the guayule rubber industry during the last 7 years in Mexico and Texas. The report of the Federal government just issued shows that during the last fiscal year there was exported from Mexico refined and crude guayule rubber to the value of $32,985,679. This was an increase of $6,757,490 over the value of the guayule rubber exportations of the preceding fiscal year. But for the interruption of the different rubber manufacturing plants during the period that the revolution was in progress the value of the product manufactured during the year would have reached nearly $50,000,000, it is said. For several months several of the larger factories in the Torreon district were shut down and nothing was done upon the ranch lands in the way of cutting the shrub.

When the fact is considered that 8 or 9 years ago the guayule shrub was unknown as a source of rubber supply and that since the discovery that it yields a good quality of the product more than $60,000,000 has been invested in the industry in Mexico and about $2,000,000 in Texas, the enormous annual production that is now being obtained is remarkable.

Practically all of the guayule rubber produced in Mexico is exported to the United States, where it enters largely into the manufacture of automobile tires and electrical appliances. Owing to the fact that most of it is mixed with the Para product when it gets to the refineries and manufacturers it loses its identity as to name so far as the general trade is concerned.

It is not known here what the production of guayule rubber in Texas during the last fiscal year amounted to, but it is said to have been considerable. The development of this industry in Northern Mexico and in the upper Rio Grande border region of Texas means that the United States is now equipped with a new element of industrial greatness. The supply of guayule shrub is practically inexhaustible. It is indigenous to a region embracing many millions of acres of land that is almost worthless for any other purpose. The shrub belongs to the semi-desert class of vegetation and grows slowly under natural conditions, but it has been proved by experiments that by cultivation it can be made to attain a commercial size in 2 years after planting. In its wild state it takes about 4 years to reach the desired height for cutting. The shrub is being extensively propagated in Mexico and Texas and experiments are being made in growing it in New Mexico and Arizona.

The two largest guayule rubber producing interests in Mexico are the Madero family, to which President-elect Francisco I. Madero, Jr., belongs, and the Intercontinental Rubber Company and its subsidiaries, which is controlled by the Rockefeller-Aldrich syndicate. This city is the chief manufacturing center of the industry. Besides the large rubber factories that are situated here a number of others are scattered through the states of Zacatecas and Coahuila.

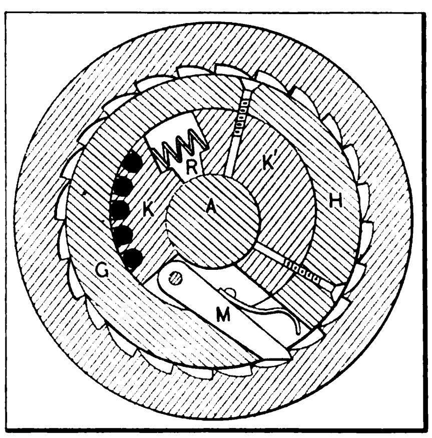

Fig. 3—The David safety starting crank, which was one of the competitors in the contest promoted by the Industrial Society for the Prevention of Accidents in the Performance of Work

One of the things which a careful automobilist should always have at his disposal is a stick which is notched at various points along its length. The stick can be inserted into the gasoline tank opening for the purpose of determining the amount of gasoline in the tank. The notches are laid off in spaces which represent a gallon a notch. When the stick is withdrawn the part which is wet will indicate the depth of the gasoline.

Letters Answered and Discussed

Use a Pair of Calipers

Editor THE AUTOMOBILE:

[2,880]—I wish to determine whether a steel shaft that I am going to use as a drive-shaft for a piece of machinery has any taper or if it is perfectly straight and if the same diameter throughout its length. Could you tell me any accurate method of determining the taper, if there is any, and how I can measure it? READER.

Davenport, Iowa.

The simple calipers are about as good a tool as there is to use for the purpose you desire. The calipers are held above the shaft, as shown in Fig. 1, and allowed to slip over the shaft in such a manner that they are not sprung as they are slipped over, but the points just fit snugly over the shaft. The calipers are set at this measurement and then tried at various points along the length of the shaft. If they will not pass over the shaft, or if they pass too loosely, there is an irregularity in the shaft which may be scaled as follows. The calipers are set to the part of the shaft with the largest diameter and then moved along the shaft. The differences are obtained by inserting a feeler gauge between the calipers and the shaft.

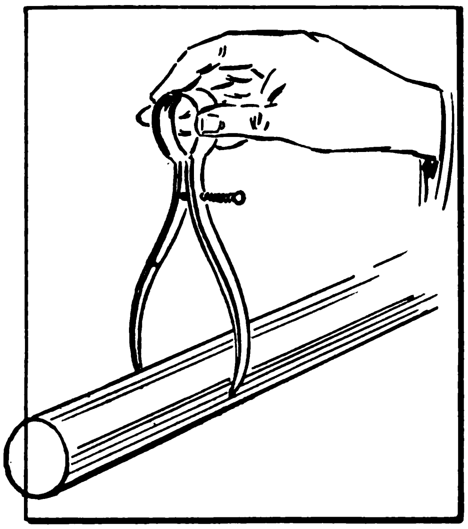

Fig. 1—Calibrating a shaft is the best method of detecting taper

Testing for Radiator Leaks

Editor THE AUTOMOBILE:

[2,881]—I know that there is a leak in my radiator but I do not know where it is. Would you kindly tell me how to go about finding it? The radiator is of the tubular type. H. W.

Mount Vernon, N. Y.

As the average car owner has no supply of compressed air on hand he may use a tire pump. The radiator is placed in a tub of water, as shown in Fig. 2, and the tire pump connected to it. A plug is placed in the water outlet at the bottom of the radiator and the air pumped in. Bubbles coming from the leak will indicate exactly where it is located.

The leak may be readily repaired by means of a little prepared solder. The solder is made so that the metal is cored out and the flux placed in the center. This will save the trouble and time of preparing the flux outside of the work of soldering. The prepared solder generally comes in sticks and can readily be used with a candle or match. If matches have to be used, two or three of them can be burned at once so that the flame will be hotter than that given forth by one match. It will often be found that a candle is not handy just at the time it is needed for the repair work.

Has Carbureter Troubles

Editor THE AUTOMOBILE:

[2,882]—Will you kindly give me reasons for my trouble? I have a single-cylinder motor which I am unable to start. Everything seems to be in good condition, but I can get no explosions except by putting my hand over the intake pipe of the carbureter and shutting off nearly all air; in this way I can occasionally get very weak explosions, but the carbureter will flood in a very short time.

I have tried adjusting the carbureter in every way possible but can get no results. The carbureter is about 6 inches from the cylinder and is connected to manifolds of 1-inch brass pipe. J. U. H.

Salem, Mass.

The symptoms given may apply to many cases and it is difficult to say what the cause of the trouble might be. Examine the manifold connection to the engine and carbureter to see if there is a leak which manifests itself at either of these points. The needle valve of the carbureter perhaps requires grinding in order to prevent too great a flow of gasoline into the float chamber. The float of the carbureter may bind or stick in such a way that the gasoline supply is not properly regulated. Take the carbureter from the engine and examine the float for the purpose of determining whether there is anything which interferes with its action. There might be an air lock in the piping from the tank to the carbureter. Do not permit any vertical bends in the piping. Perhaps there is no vent in the fuel tank to permit the air to enter as the gasoline leaves. As a final resort, if the above causes are not suitable to your case, the carbureter should be sent to the factory for examination as it is probably defective. This advice is based on the assumption that the other parts of the motor are in good condition.

Wants Non-Freezing Solution

Editor THE AUTOMOBILE:

[2,883]—During the Winter months I store my car in a garage where the temperature often drops below the freezing point. Consequently I have to drain my radiator to prevent it from being damaged. Do you know of any solution which one could add to the radiator water to prevent freezing under ordinary temperature conditions, and, at the same time, be absolutely harmless to the circulating system? W. C. MAND.

Chatham, N. J.

Denatured alcohol is about the most commonly used solution; it is harmless and effective. A 20 per cent. solution will freeze at about 10 degrees above zero; this is a proportion of 1 quart of denatured alcohol to 1 gallon of water. A 30 per cent. solution, 1 1-2 quarts of denatured alcohol to 1 gallon of water, would freeze at about five degrees below zero. Freezing point of water is at 32 degrees above.

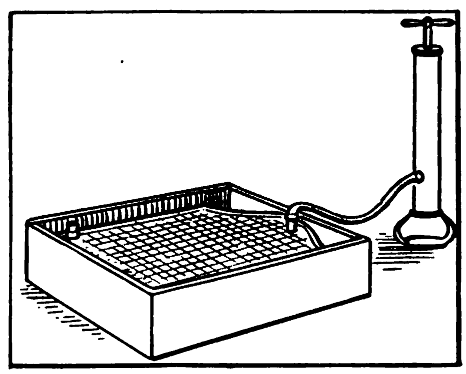

Fig. 2—Illustrating method of testing for leaks in radiator

Care of Mohair Tops

Editor THE AUTOMOBILE:

[2,884]—What is a good dressing to make mohair tops waterproof? How is it applied? MURRY FAHNESTOCK.

Alleghany, Pa.

In the issue of September 7, on page 394, there is an answer to a similar question which will cover this case. In other words mohair tops should not be dressed.

Wants Article on Transmission

Editor THE AUTOMOBILE:

[2,885]—I am very much interested in your paper and would like to see an article on transmissions, progressive vs. selective types. Just at present I am having trouble with my gearset, having broken a countershaft and two main shafts. The gears are noisy and rumble while in mesh and the car jerks when going slow if I disengage the clutch with either first or second gear in mesh.

J. W. REEVE, JR.

New York City.

The gearset you employ is no doubt inadequate to fit the needs of the car and should be replaced by one made by a reliable concern. It is very well possible that the clutch is also in need of refacing if it takes up fiercely at low speeds. If it is a leather faced cone clutch it should be blocked out of engagement by propping the pedal and castor oil applied. A liberal coating of oil should be given and allowed to stand over night.

Uses Too Much Oil

Editor THE AUTOMOBILE:

[2,886]—As a subscriber to your valuable paper, I would like to ask you some questions regarding my engine.

The front cylinder seems to let oil through it when running; I have taken the cylinder head off and find that the rings are tight. I poured oil in the cylinder with the head down about 1-2 to 1 inch from the top and poured oil into the cylinder. It held the oil tightly and the cylinder has splendid compression.

The engine runs very well but it consumes entirely too much oil. As there are no leaks in the crankcase outside of a few drops, I cannot understand where it goes or how it gets into the top of the cylinder. None of the other cylinders give any trouble in this way the trouble being entirely confined to the cylinder nearest the radiator. It gathers carbon quickly while the other cylinders rarely have to have their spark plugs cleaned; the motor runs as noiselessly as the majority and is economical in all respects except in the matter of lubricating oil.

ED. C. BATES.

Clarksville, Tenn.

If you will take the piston rings out and replace them you will find that this trouble will disappear. The trouble is that while the engine is running the oil will be forced past them because they are worn.

Illustrates Score Board

Editor THE AUTOMOBILE:

[2,887]—I take pleasure in sending you a photograph of the score board of the fourth annual 200-mile race of the Quaker City Motor Club (reproduced in Fig. 3), held in Fairmount Park, October 9. I am sending this because it is a complete story of the standing of the cars in the race, and because as a work of art it stands alone in this respect. This board is 22 ft. high by 44 ft. long, and the excellent system that the writer inaugurated as official timer and scorer enabled the public in 95 per cent. of the time to obtain figures from fifty seconds to one minute and ten seconds after the cars had crossed the tape. In other words, to show our excellent timing and scoring there was only a delay of from fifty seconds to seventy seconds after a car would cross the tape before the painters would have the score recorded on the board.

No time in the history of automobile racing has there been a score board of this character provided that afforded a correct record of the race and the score so quickly recorded.

Believing that this photograph and the above information will be of interest to you, and that you kindly acknowledge receipt of this, I remain,

Yours truly,

PAUL B. HUYETTE, M.C.

Philadelphia, Pa.

A Little Road Incident

Editor THE AUTOMOBILE:

[2,888]—As a little illustration of how hospitable people will be along the roads I wish to relate an experience I had the other day while taking a short cross-country tour up in Connecticut. We were going along the road at a fair rate of speed when the car skidded in turning a corner and ran into a telegraph pole. The steering knuckle snapped and we were left helpless upon the road.

Evening was approaching and a rainstorm threatened at any moment, the wind blowing out of the northeast with all the discomfort accompanying it which a northeaster can possibly bring with it. There were two ladies in the car, and the roads were in no fit state for any pedestrian, so we were "up a tree."

While we were debating what to do under the circumstances, an old farmwagon hove in sight and, seeing our plight, stopped. After considering us for a short time in the way of countrymen, he announced that he had some neighbors who lived nearby and they would be glad to shelter us from the rain. It had started to fall. Well, to make a long story short, we sat down to the best kind of a New England dinner and the farmer's son guarded the machine until help arrived from a nearby village which was blessed with a garage.

C. Q. D.

New York City.

Little Bits of Motor Wisdom

Pertinent Pointers o1 Interest to Repairman aad Driver

Cam Actions—The principle of the wedge is not applied in a more useful form than in the cam. In nearly all machines some part of the mechanism is manipulated by means of the action which is imparted to its various parts by a cam arrangement. In the internal combustion engine this principle has been utilized to the greatest extent in the operation of the valve mechanism. To secure the greatest efficiency possible with a given engine the valve action must be correctly timed, the gases must be admitted to the cylinder at the proper instant and must flow into the cylinder in such an interval of time that the required weight of charge is in the cylinder and at the same time not overlap any other part of the cycle in such a way that it will interfere with it.

In the case of an average valve timing, which was compiled by taking the timing of several different cars and striking an average between them, the cams were arranged so that the inlet cam held open the valve which it manipulated during the time that the crank passed from 10 degrees past the upper dead center until it reached a position 30 degrees past the lower dead center. The exhaust cam in this case was arranged so that it held the valve open from 40 degrees before lower dead center on the end of the explosion stroke to 5 degrees past upper dead center. It will be noticed that while the inlet valve was held open for 110 degrees the exhaust valve was held open for 135 degrees. This difference in the length of time that the valves are held open will entail a difference in shape of the cams which may be well brought out by illustrating the cams on an average engine. The cams shown in Figs. 2 and 3 bring out the difference in contour between the exhaust and inlet valve cams. The cams which have the longest face are for the exhaust action while the shorter faced cams are for the inlet. If the actions of the inlet and exhaust valves were similar so far as time of opening were concerned the shape of the cams would naturally be exactly similar, though they would be set at a different angle on the camshaft.

There are many variations so far as the relative valve opening and closing times are concerned; these variations being based on the different theories of the designers of the various makes of engine. There are two principal theories, however, which hold sway at the present day in the inlet timing of the four-cycle motor. According to one idea the inlet valve should open before the exhaust valve closes so that the entering charge will aid in scavenging the motor by sweeping out the remainder of the dead gases. The other scheme, which is used by the majority of engine builders, is to have the inlet valve open shortly after the exhaust is closed. In the average engine above mentioned, the period between the closing of the exhaust and the opening of the inlet valves is 5 degrees in the crank circle.

Using the Hacksaw—The hacksaw is among the tools which may be used for a variety of purposes. Four of the different pieces of work which may be accomplished with this useful tool are shown in Fig. 4. The operation indicated by A, in this illustration, is one of cutting a piece from a solid block. This is a tedious piece of work at best, but could not be accomplished by any other hand tool as simply as it may be done by means of the saw. The work may be clamped in the vise in the manner most convenient for the workman to proceed with the operation and may be shifted from time to time according to the manner in which it is required to make the cut.

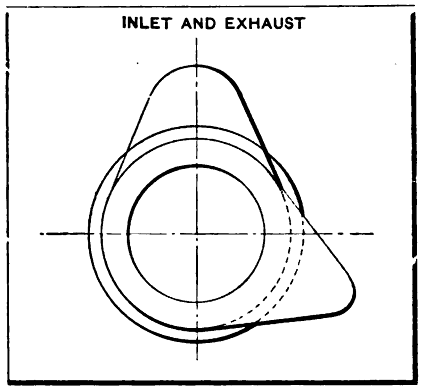

Fig. 2—Showing the relative shapes of the inlet and exhaust cams

At B the operation of removing a tight bushing without damage to the part containing it is shown. If the bushing is removed by driving it from the pinion, there is a great chance that the pinion would be marred or the teeth destroyed or damaged in some way. By using the hacksaw a simple vertical cut or two may be made which will permit of the removal of the bushing without trouble. A wise precaution which may be taken in performing this operation or any other in which the part is clamped within a vise, is to slip a piece of wood between the jaws of the vise and the part enclosed within them. The wood being so much softer than the metal will take up the squeeze of the vise and hold the part firmly, yet at the same time the sharp metal edges of the vise will not be able to mar the metal.

It may sometimes be necessary for the automobilist who strays far from the beaten path to make himself a gearwheel which will at least fill the position of a disabled member for a short length of time. At C this operation is being carried out. It will take a long time to do it, but in the case where the automobilist is far from the factory or nearest service plant it will perhaps take him a shorter time to set to work with the saw than it would for him to wait until the needed part ar-

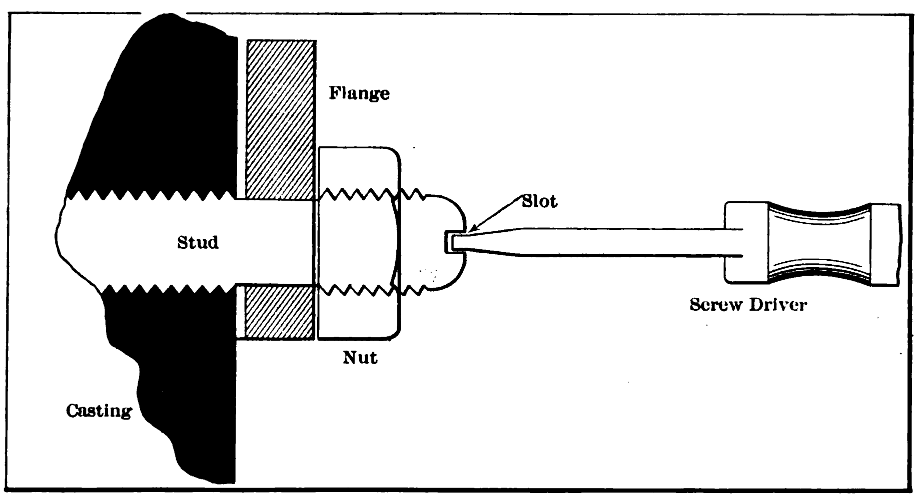

Fig. 1—A case where a stud may be fitted which can be adjusted by means of a screwdriver

rives. The broken gearwheel will serve as a guide and template in laying out the new wheel; or, if the old wheel be lost, the diameter of the pinion required may be measured on the machine itself. The number of teeth in the wheel will depend on the function it is called upon to fulfill. It may be easily calculated at any rate by remembering the simple rule that the number of teeth upon a gear wheel of any size varies directly with the diameter of the wheel when the pitch of the teeth is constant. The pitches of the teeth on wheels which operate in mesh with each other are naturally the same.

It may often be the case that a screw of a certain size will be required at a place and that there are none available. If the operator is equipped with a hacksaw the problem will resolve itself down to about a half hour's work. A bolt of the same size as the screw required may be clamped in the vise. The head is then sawed off by a horizontal cut. The next operation is depicted at D. The operator has merely to make a vertical cut into the top and a perfect screw will be made. The threads may be filed from the top if it is desired.

Screwdriver Handier.—There are many instances where the parts which require frequent adjustment on the automobile are not so accessible as they might be. In fact accessibility is just becoming prominent in the minds of those to whom the world looks for the best in automobile design. In the automobile, as well as in all new mechanical devices, the first developments lie almost entirely along the lines of the really essential features, while those things which would tend towards the greater comfort and convenience of the operator of the machine, and yet are not an absolute necessity in the construction, were not considered of prime importance.

It will often happen that a nut is fitted upon the motor at such a place that while it may be entirely within reach before the motor body is mounted upon the chassis or the motor itself placed within the chassis, yet after the assembly has been made it requires a series of gymnastic feats to tighten the nut after it has been removed. The nut may be brought home a considerable distance and yet it will be a physical impossibility to give it the final turn which will produce the necessary tightness of fit. This is generally the case where the wrench can not be properly applied owing to the cramped position.

The screwdriver can often be used in cases where it would be impossible to attempt to use a wrench, so that if the end of the stud is threaded as shown in Fig. 1, it may be screwed home by the screwdriver. The nut in this case would act merely as a locknut. The screwdriver would have to be large in order to do its duty properly in a case of this kind, as there would naturally have to be a considerable amount of force employed to turn the stud home as tightly as if a wrench were employed. The greatest advantage in the use of a wrench is the amount of leverage which can be employed when it is desired to tighten the nut as firmly as possible. A screwdriver, however, if composed of good material so that it will not crumble away at the end if pressure is placed upon it, will be perfectly capable of turning the nut as far as it is necessary. In many instances the end of the screwdriver may be flattened and the wrench placed over this part of it.

It will be a matter of but a few minutes to make the change described above and of applying the screw-headed stud to a part such as is depicted in Fig. 2. The nut will take some of the strain, so that it will not all be upon the threads within the tapped hole. The screwdriver will be much handier to manipulate in the cramped space than the wrench, and will be found to give adequate satisfaction so far as tightness is concerned. A point to remember in connection with the neatness of the job is that the length of the end of the stud screw should be regulated so that there will not be a long shank projecting out behind the end of the nut. A small amount may be allowed; that is, enough so that there will be no danger of the stud being shorter than the end of the nut.

Use Straps for Baggage—The ancient rope is one of the most useful of man's servants, but in spite of this fact it has its limitations, which cannot be denied. One of these limitations is in the line of its use as an instrument in holding baggage upon the automobile.

A buckle is ever so much more convenient than a knot, no matter with what skill the latter may have been tied, and when the weather happens to be rainy the truth of this statement will be demonstrated. A strap may easily be unbuckled, and then, if it is desired to fasten it in any other place after changes have been made, it is very simple to punch a new hole in the strap at any place along its length and fasten it at that point. When baggage is carried in two or three suit cases which are tied together it is much more simple to have them bound by straps in place of ropes.

The leather of the strap should be well taken care of. This is a point which is often overlooked, and yet it is of considerable importance so far as economy is concerned. A little neat's foot or castor oil will keep it pliable.

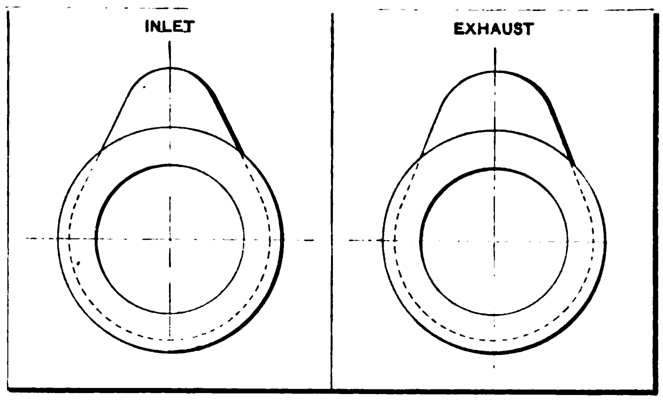

Fig. 3—The inlet cam has a shorter period than the exhaust

When a Valve Is Disabled—It is not necessary to throw the hands up in despair if the valve on one of the cylinders of a multi-cylinder engine is disabled, as it is very well possible to get home on the other cylinders without a great amount of trouble if a few simple steps are taken. The inlet passage can be sealed so that it is impossible for the cylinder to draw in a charge of fuel. The exhaust valve should also be closed so that there will be no chance for the motor to suck dead particles into the cylinder.

A good method of sealing the valves is to open the joint where the gasket is inserted and putting a blank gasket in place. The cover is then bolted on, and the engine is ready to be operated in spite of the break. The motorist is able to get home in this way without the slightest fear that any damage will be done to the motor further than the valve breakdown.

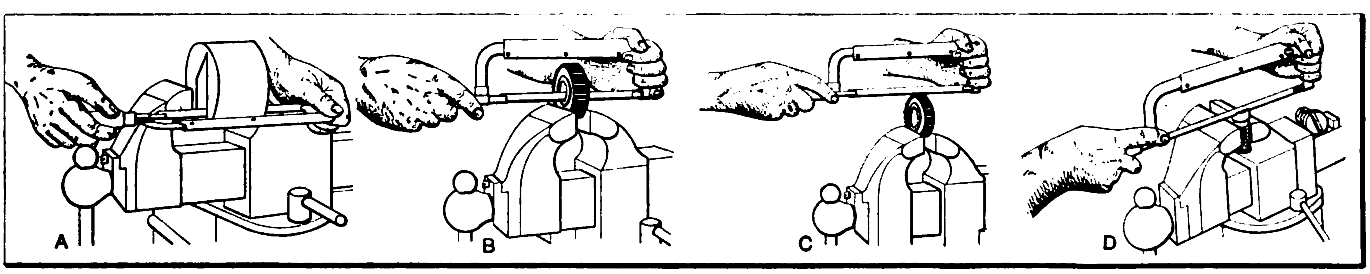

Fig. 4—Depicting four different operations which can be carried out by means of a hacksaw

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

Used Leather Washers

Editor The Automobile:

In answer to your interesting invitation to automobilists to send in a description of their temporary or permanent repairs, I am sending you a sketch (Fig. 1), showing how I made a temporary road repair on my left front wheel after the cones had burst when descending a steep hill; and by the use of three leather washers went merrily on my way.

The illustration shows a section through a hub. The end of the axle A rested on ball bearings, which were located at B. P is a cotter pin through the nut, and C the cap. The hub of the wheel is indicated at H and is shown riveted to the wheel. It was at the point W that the accident happened, and at the time I had only been driving and owning a car for four weeks.

I went to a farmhouse and procured a piece of leather, which I cut into washers. These washers I fitted as shown at W. I took a great deal of care that this point was very copiously lubricated after I had fitted them as shown, and I am sure I could have ridden 100 miles without damage to the car in any way.

This repair took me 45 minutes, and considering the short length of time that I had been driving the car, the scheme was a great success, as I had no trouble in reaching a point where a permanent repair could be made. W. B. White.

Zelienople, Pa.

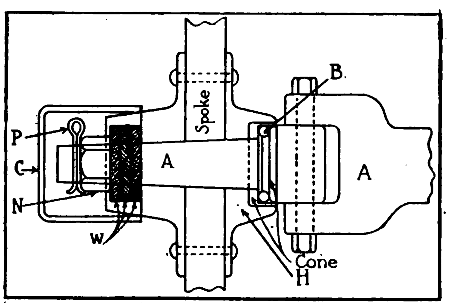

Fig. 1—A repair made by a reader when the cones had failed in descending a hill

Made a Tire Pump

Editor The Automobile:

In answer to your invitation for readers to send in their roadside experiences and repairs, I am sending you a description of a tire pump which a friend and I made, and although it is not exactly a repair, may interest you, since it is along the same line.

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor The Automobile.

The pump was made out of fittings which can be found in any plumbing or machine shop, and is so simple that it is merely a matter of screwing the parts together. It will do the work every bit as well as a pump which costs many dollars, and yet does not cost more than $1.50. It fits into the sparkplug, and the engine does the work.

The pump is shown in Fig. 2 and consists of but nine pieces of material. Reading from the left to the right on the illustration the inlet is at I; A is a 3-8-inch check and forms the inlet piece. The T-piece P screws into the sparkplug and is of 1-2-inch standard gas pipe; upon the top of this piece is fitted a release cock C. Another check of the same size as the first screws into this at A, and fitted upon the top of this there is a pressure gauge G. The union U is inserted in the line for the purpose of connecting the hose H to the pump. The hose H leads directly to the tire and is fitted with a valve for connection. This pump will put pure air into the tires and will allow the engine to do the work without any trouble.

Ed. C. Bates.

[The opinion of our readers on these contrivances and repairs is invited—Editor.]

Made a Rope Tire

Editor The Automobile:

Once while I was out on a rather rough road I blew out one of the rear tires. I had been going along very steadily at a moderate rate, when suddenly the tire blew out. I stopped the car and after examining the tire was at a loss as to how to proceed, as I did not wish to completely ruin a casing which was bad in only one spot. The road was very rough and I could not proceed on the flat tire without hopelessly cutting it up, so I took a piece of rope and by binding it on tightly after removing the casing from the rim I made a fair imitation of a tire, which took me to a garage without cutting either the rim or the casing. I. H. P.

Detroit, Mich.

Broke Valve Spring

Editor The Automobile:

Once while running along a rough piece of road I happened to snap a valve spring. I have always attributed this incident to the roughness of the road, as the spring broke just as the car went into a deep rut. I was puzzled for a time, and was just going to throw the broken spring away in disgust, when a thought struck me that by inserting a washer between the two pieces of broken spring I might be able to make it work. I tried the scheme, and to my great delight found that the engine ran along as well with the double spring as it did before the accident.

As I was making the repair it struck me that there would have been another way of doing it, in case the spring did not work well when fixed in this manner. I thought of taking a piece of pipe and fitting it to the right length and then placing the washer on top of it, thus using only part of the spring. But as the other plan worked perfectly, I was amply satisfied. I think that this is a good lesson not to hastily throw away broken parts. H. W. W.

New Rochelle, N. Y.

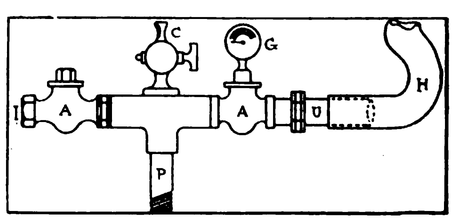

Fig. 2—A tire pump made from the simple fittings common to any plumber's shop

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Curves for $350

Editor THE AUTOMOBILE:

My idea of what a low-priced car should be will be found in the sketch enclosed (Fig. 1)and the added description.

Curves, all curves you will notice; late investigations have shown just how great are the losses in power on present models because of the want of curves. The windshield is not an addition, but forms a part of the machine. The door when swung open swings a part of the windshield with it to permit easy ingress to the car. There is room for three people, the operator sitting in the middle. The reason for this is that springs, to permit easy riding, must be very soft. Under these conditions, for the driver sitting to one side, when alone, is to have a lopsided machine; further, it is best because symmetrical, other things being equal.

Mudguards and top are put in position when needed, a further reduction in wind resistance; and, for another thing, there is no good reason to keep an umbrella over one's head because it may rain some day. The rear part of the car, all enclosed, provides space to pack spare tires, top and mud guards, and leaves the care more sightly.

A single-cylinder engine of 4 1-2 x 6, giving a maximum speed of 40 miles per hour, which I think is sufficient. Since two horses cannot run faster than one, the additional cylinders of a 4-cylinder engine add to complication, but not to power or better service. A single chain, enclosed against dust; planetary transmission controlled by two interconnected pedals (high and low), for the right foot to manipulate; for the left foot, the transmission brake, also the spark control, arranged in a curved slot and self-locking, should be installed. The low speeds (when hampered by traffic) are had by coasting, after the manner of motorcycles; the clutch is left in, and by throwing the left foot to the extreme left against a spring the fuel and spark are cut off, the car coasting.

The fuel control is located on a sector beneath the steering wheel. There is no carbureter, generator or injector, nor a throttle; I do not think it possible to devise an automatic carbureter (the very great number offered to the public alone will support my contention); therefore I rely on hand control, doing away with the most troublesome part altogether. The throttle serves to cut down the efficiency of the engine to a very great extent, and speed control by spark advance and coasting I believe more desirable.

The entire upper part of the car is taken up by two tanks, one containing kerosene, 7 gallons for fuel, and 3 gallons of water. The other 1 1-2 gallons of gasoline for starting duty, and 1-2 gallon of oil. No pressure, only gravity required. High-tension ignition by battery and three plugs.

The radiators are hidden in the ventilators on each side, two finned tubes in each. The entire front of the car is open to admit the air freely. The car is 43 inches high, 53 inches at the windshield, and 64 inches with the canopy. Wheelbase, 80 inches; tread, 56 inches. The springs in this drawing are made to yield to all loads alike, and are not visible from the outside. I would not mention this, but it might be thought a defective drawing otherwise.

It should sell for not more than $350.

New York City. P. G. TISMER.

Idea of $1,500 Car

Editor THE AUTOMOBILE:

Seeing that you ask the readers of your magazine to send in a description of their ideal 1912 car, I am sending mine.

My 1912 car would have a 22-horsepower, 4-cylinder motor of the T-head type, cast en bloc. It should have a bore of 3 3-8 inches and 4 1-2-inch stroke. All valves should be enclosed in a dustproof cover. The ignition should be of the Bosch dual system. Lubrication of the splash type. The carbureter should be of the float-feed type, with an adjustment on the dash.

The clutch should be of the mutiple-disc type and run in oil. It should be housed with the gearset, which should be placed amidships.

The transmission should be selective type, with three speeds forward and one reverse.

The drive should be by shaft with two universal joints, to a full floating rear axle. The front axle should be of the I-beam type with large steering knuckles.

The frame should be underslung and inswept in front, because the underslung frame makes the car safer and makes it possible to have the car look better. The insweep in front is to give the car a short turning radius. The springs should be long, flat, semi-elliptic, with shock absorbers on the front and rear.

Tires should be 36 x 4-inch front and rear, on Firestone demountable rims. Wheel base should be 106 inches.

Control levers should be on the right side; there should be a foot accelerator, and pedals should be standard. The steering wheel should be 18 inches in diameter.

The body should be of the two-passenger torpedo type, with the levers on the outside, and on the rear deck there should be placed the gasoline tank and the spare tire.

Equipment should consist of a top and cover, windshield, speedometer, three electric lamps, two headlights and gas tank, the headlights to be lit by a flash autolighter; electric horn, storage battery and one extra rim.

Price should be about $1,500.

Walton, Pa. X. Y. X.

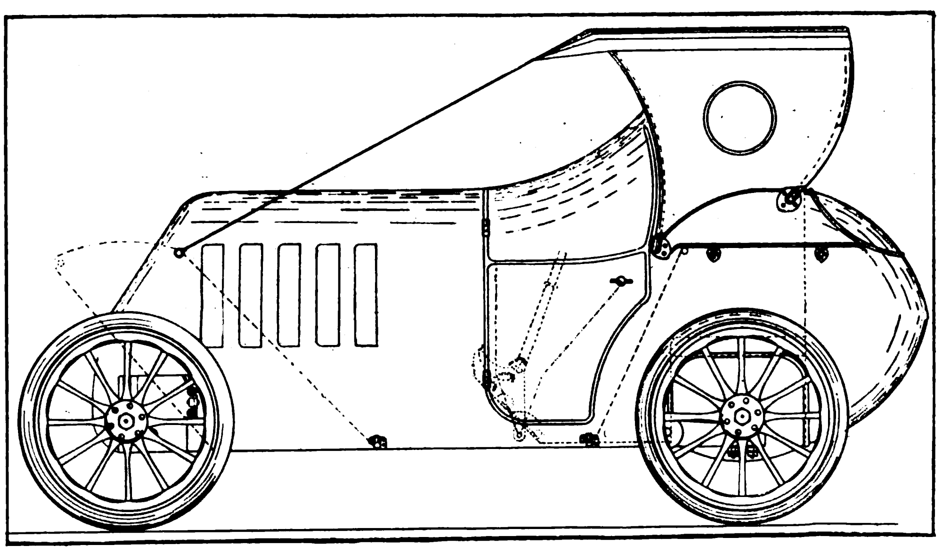

Fig. 1—Illustrating the body desired by a reader at a cost of $350

Systematic Handling of Car Repairs

SYSTEM, while it may seem complicated at the time of its first introduction, soon proves that it makes things simpler than they were before it took effect. The gain in time and labor by the use of a suitable system is hardly to be overestimated; or is the use of the system itself exaggerated but in very rare instances. In the automobile repair business, this latest branch of the machine trade, system has but recently been introduced, but already have its advantages made themselves felt. Increased efficiency and consequently greater economy in material and labor are the consequences of a live system applied in these quarters.

Fig. 1—Record of a car, showing the total amount paid by the user of a car, including repairs

In the following is given a description of the card index system used by one of the New York automobile selling concerns, the Abbott-Detroit Motor Company, 1670 Broadway, whose repair department is located a short distance from the store. This concern handles the Abbott-Detroit and Regal products in the Metropolitan district. The system used is simple, consisting of but two small cards, both of which are 5 by 8 inches. One is used on both sides.

The principal card, Figs. 1 and 3, is always kept at the office of the company and is printed on both sides, the front being illustrated in Fig. 3 and the rear in Fig. 1. On the front are entered, besides the make of the car, the buyer, the date of the sale and the name of the salesman who closed the transaction. In case of a used car being traded in the make and allowance made for it are stated, and the salesman's commission, which must, like the preceding figure, be deducted from the selling price of the car, is given on the same line. In case the automobile is insured the details of this fact are given, including the amount the machine is insured for, the price of the policy paid and the date when this has been done. Half the card is left over for remarks of some nature or other, as, for instance, what service the car sold is intended for, what territory it is to work in, or the like; or, if the car sold is a second-hand one, some confidential notes of interest to the buyer, but charily guarded by the vender, may find their place under that innocent heading Remarks.

The prices given on the reverse side of the card, Fig. 1, for some equipment bought with the car are, of course, fictitious, but they illustrate the manner of keeping a simple yet efficient account of every car sold. In the instance shown in the illustration the selling price is $1,540.45, from which must be deducted the allowance for the old car traded in, which is $570, as well as the salesman's commission on the deal, amounting to $75. This leaves a net selling price of $905.45.

The right-hand side of the card in Fig. 1 is reserved to contain the account of the car's history after its sale so far as the company is concerned in this matter. The first item has been entered on September 15, amounting to $57.25 for repairs. If reference is made to Fig. 2, the repair and material order of the repair department of the company, it will be seen what items have gone to make up this $57.25, as well as in what way the repair department is run.

A. G. Jones, buyer and owner of the car named on the sheet, had obviously met with a collision, as is indicated by the nature of the repairs ordered when he handed the automobile over to the company. He asked for a new steering knuckle to be fitted, as well as for a pair of headlights to be installed on his car. This shows that some cards tell a good deal to the man who knows. Besides there is little doubt but that this was Mr. Jones' first car and that he tinkered with it as well as he could; hence the spoiled valve adjustments, while the disordered transmission gear tells of a tyro-like treatment of the car.

REMARKS

Fig. 3—Sales record of car, containing exact data and remarks on transaction between automobile seller and buyer

knuckle to be the part No. 593 on the Model B touring car, then this number is entered under the heading Parts No., while 1206 is the registration number of the individual part fitted to the car and under which it was kept in the shop. Likewise headlights bear the part No. 3182, but the two particular lights fitted to Mr. Jones' car are numbered 3477 and 3478, respectively, the bracket being kept together with the lamp.

Remembering that charges on the sheet illustrated are not the same as those made in reality, let us assume that the steering knuckle is valued at $11.36 and the two headlights at $16.67, which prices are entered under the heading so marked. Under Extension, Fig. 2, on a repair sheet are generally charged the repairs of parts covered by a guarantee while it lasts, but made after it expires. Inspecting and adjusting the timing of valves were charged to Mr. Jones at $6.29, while the work done on the change-speed gearset cost him $19.93. Adding to these charges the wages paid to the workman who executed the job, the total bill of $57.25 is arrived at.

The principal cards are kept in alphabetical order, while the repair cards, Fig. 2, one being filled out in every case of a repair job, may be either filed under the car numbers or together with the principal cards. In all cases, however, all the cards are kept in the office after the repairs have been finished. The principal cards, Figs. 1 and 3, of course, never leave the office, while the blanks for the repair orders, Fig. 2, are kept in the shop, filled out by the superintendent of the repair department and then handed over to the office.

The particular system above described is used, with some minor variations, by many other concerns besides the one named and has been found to be effective enough by those who have introduced it.

Careful Supervision Will Surely Add to the Life of a Car—It can never be said that a car is in good condition if it is allowed to leave the garage with the tire casings hacked to pieces or with deep cuts appearing on the surface. One of the greatest causes for the rapid deterioration of tires is the fact that water will work through the cuts and rot the fabric. This will eventually lead to a burst which could easily have been prevented with a little energy and foresight. In the points mentioned, as well as in all the other details which will present themselves at different times to the car owner and driver, a careful supervision will be rewarded by a prolongation of the life of the car and increased comfort in driving.

Calendar of Coming Events

Shows

Jan. 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 22-28.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17.........Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24.........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Week Feb. 22.....Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Meetings, Etc.

Nov. 20-24........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 22...........Road Users' Day, under direction of Touring Club of America.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Oct. 14 (to 26)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 28............Brooklyn, N. Y., Sealed Road Handicap for Schimpf Trophy, Long Island Automobile Club.
Oct. 30............Minneapolis, Minn., Hill Climb.
Oct. 27-Nov. 3.....Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 30............Harrisburg, Pa., Economy Run, Motor Club of Harrisburg.
Oct. 31............Shreveport, La., Track Races, Shreveport Automobile Club.
Nov. 2-4..........Philadelphia Reliability Run, Quaker City Motor Club.
Nov. 3.............Newark, N. J., Reliability Run, Newark Motor Club.
Nov. 3............Newark, N. J., 125-mile Automobile Endurance Run, Newark Star.
Nov. 3-4..........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27...........Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30...........Los Angeles, Cal., Track Races, Motordrome.
Nov. 30...........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25 26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign

Nov. 3-11.........London, Eng., Olympia Show.

THE AUTOMOBILE

Vol. XXV Thursday, October 26, 1911 No. 17

THE CLASS JOURNAL COMPANY

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Does It Boost Good Roads?

THE Glidden tour was taken South to boost the good roads cause. Does it boost the good roads movement and does it boost the automobile business to take seventy cars through a country in which there are over thirty streams that have to be forded? A tour went over this same route two years ago and these same fords were in existence then; they had to be forded then, but fortunately the weather was, and had been, dry at that time and the water was low. In two years there has been plenty of time to build bridges over some of these fords, in fact over all of them. It should not require an annual demonstration of running an automobile through water and mud, or having it towed by oxen or horses or mules, to impress on the populace the necessity of good roads. The question then arises, Is the present tour worth while from a good roads point of view? This remains to be seen. If immediate work is not begun bridging these fords and getting stone road material to the quagmire road sections then it is not worth while. What the section of road from Natural Bridge to Martinsville needs is immediate action rather than any more tours. The experiences of the past week with the Gliddenites is not a good advertisement to those Southern States. It is going to repel touring from that locality rather than encourage it. You can talk of enthusiasm and receptions, but if you have not roads automobiling is not worth while. The roads must be built. The people have known for several years just how bad these roads are when it rains. There is not any use of advertising the fact any further; it would have been better without this recent exploitation. Work is needed.

Much work has been done on these roads within the last three years, but still they are impassable when it comes to the worst. A chain is but the strength of its weakest link and a road is but as good as its worst spot. One old road builder defined a good road as being one that is good in bad weather. This is a good definition. Any dirt road can be good in fine weather; any clay road can be all right when there are not any rains. What better roads could be desired than a dragged gumbo road in dry summer months? but with all of these dry-weather roads it is the same story of impassability in rainy periods. What America needs is the road that is good in bad weather. This is the kind of road that the East is building and this is the kind of road that must be built in the South, and in the Middle West gumbo and black-soil districts. It does not call for so-called automobile tours to let the people know this. This fact is already known. Tours are excellent things if some actual good is achieved as the tour goes along. It would pay the South to issue bonds and build a good stone road into the heart of its territory and then run a tour over it in the rainy season to demonstrate to the entire nation that it has good roads —roads that are good in bad weather.

* * *

Introducing Motor Trucks

IN these days, when many dealers in pleasure cars in different sections of the country are taking on a line of commercial cars, it is imperative that such dealers give some study to the task they have undertaken. They imagine that because they have been successful in selling pleasure cars they cannot but be successful with commercial vehicles. This does not necessarily follow. A commercial car is a business investment, whereas many pleasure cars are purchased for pleasure and outing purposes. The work of introducing the commercial car is a big task. In the first place the pleasure car dealer is ignorant of many factors entering into the situation. He is ignorant of the details of his truck construction; he is ignorant of the sphere of freight transportation within big cities; he is ignorant of the problem of commercial vehicle maintenance; he is ignorant of the troubles with the truck driver; he is ignorant of the ins and outs of the teamster situation in the city streets and depot yards; in a word, there are ten or more important factors that must be carefully studied before the pleasure car dealer is in a good position to take the truck matter sensibly in hand.

The truck is in many cases a good engineering job. The strength of the axles, springs and wheels is adequate; the body facilities meet with all requirements, and the design of motor or gearset is satisfactory for the present. These are but small items in the big problems of handling trucks. The first big problem is the selection of a proper system of trucks or delivery wagons for the needs of the buyer. It is folly to sell a mercantile store 3-ton trucks if the demands of their business are such that 1-ton trucks are best suited for the work. It is poor policy for the salesman to make a sale where he himself feels that his truck is not best suited for the work. It would be better in the long run not to make such sales. Some truck concerns have been conscientious in this matter and when they did not have types of trucks best suited to the needs of many of their customers they took the matter in hand and brought out new models of load-carrying capacity to suit the needs of the buyers in question. This is good truck policy and should be imitated by others. A dealer does not lose much in the long run when he looks after the interests of his buyers in this matter of truck selection. Some dealers may argue that it is not their sphere to say exactly what load capacity or type of truck is best adapted to the particular needs.

The dealer should know better than the buyer. If the dealer does not know then he should go out and study the problem. It is a certainty that the buyer does not know. The motor truck is an untried quantity to him and he will be apt to draw comparisons between it and his horse-drawn systems. Comparisons are dangerous in this field, because the buyer is ignorant of the abilities of the truck; he will underestimate certain qualities of it and may overestimate others. He cannot properly compare; he does not know enough about the trucks to make such comparisons. Here is where the field of the salesman comes in. The salesman must get out of the salesroom. His work is not one of talking mechanical constructions or elucidating on engineering problems; his is a duty of meeting conditions front to front. He must study the problems of freight delivery in the congested zones of cities and also in the suburban and semi-suburban districts. He must study the fields best filled by gasoline types of machines and he must also study the fields for which the electric is specially qualified. This is not any child's play; it is real labor—labor that can only be accomplished by the sweat of the brow.

But the truck dealer has more problems to solve. He has to solve the question of the driver and other workers on the truck. The driver of the horse-drawn vehicle has set his pace to suit horse-drawn traffic; he is not working on a pace for motor-driven vehicles. Consequently the efficiency of the truck is held back by the horse-pace of the driver or other truck attendants. This field must be cleaned up. The horse driver, satisfied to sit and wait for two hours while a big load of small packages is being put on, is a stumbling block to truck introduction. Where small packages are involved a crate system is advisable. It is more expensive to keep a big truck idle for two hours during a slow loading process than to keep a horse-drawn truck idle during the same period. In two hours the motor truck can travel sixteen miles, but the horse team could not make over 4 or 6 miles. New facilities for loading and unloading must be worked up, otherwise the truck will be held back by the old horse-order of things. The driver must be speeded up; otherwise the efficiency of motor delivery will be held back.

Chairman Butler Killed on Glidden

TIFTON, GA., Oct. 25—(Special Telegram)—Samuel M. Butler, Chairman of the Contest Board of the American Automobile Association, was instantly killed this morning, and P. B. Walker, Referee of the Glidden Tour of 1911, and Mrs. Walker were seriously injured when the Cunningham pacemaking car in which the official party was riding broke a steering knuckle and plunged off the road into an adjoining field. Mr. Butler was caught under the tonneau when the crash came and was crushed to death in the twinkling of an eye. Referee Walker was badly shaken up and injured internally, while Mrs. Walker suffered a broken arm. Both are in a Tifton hospital.

At the time the accident occurred the car was going at about 35 miles per hour over a very good road. While the cause of the breakage is not definitely known, it was in all probability due to crystallization of the knuckle while the car was being subjected to the knocking and pounding on the terrible roads in Southern Virginia.

It was at first stated unofficially by THE AUTOMOBILE representative that owing to the distressing accident the tour would be abandoned at Tifton. This place, according to the route book of the Glidden tour is 41.9 miles from Cordele, the over-night stop. Later it was announced that the run would be continued on neutralized running time.

The late Samuel M. Butler.

Samuel McKnight Butler was born Sept. 13, 1866, and was therefore 45 years old. He is survived by a widow and two children—a boy of 18 and a girl of 16. Their home is on Carlton street, Brooklyn, N. Y.

Mr. Butler was first assistant secretary and then secretary of the Automobile Club of America, holding the latter position at the time of the formation of the American Automobile Association, in the organization of which he was largely instrumental. He retained his position as Secretary of the A. C. A., until he assumed the chairmanship of the Contest Board of the American Automobile Association in December, 1909. He was also at one time secretary of the Aero Club of America, and made quite a number of ascensions during his incumbency of the office. During the Spanish-American War, Mr. Butler served with credit in the Signal Corps of the United States Army.

S. A. E. Headquarters in London

Interest in the approaching European tour of the Society of Automobile Engineers is growing. As previously announced the headquarters in London will be at the St. Ermin's Hotel, St. James' Park, London, S. W., near Westminster Abbey and the Houses of Parliament, and within a short walk of Whitehall, Pall Mall, Piccadilly, the Strand, and other leading thoroughfares of the English metropolis. The hotel is the headquarters in London of the Motor Union of Great Britain and Ireland.

The hotel management has officially quoted a price of from 6 shillings and 6 pence ($1.75) per day up for each person according to size and position of room selected. This price includes lights, attendance and bath and table d'hote breakfast. Rooms with private baths can be secured from 9 shillings ($2.25) per day up per person without meals. Suites of two rooms and bath (without breakfast), can be had from 1 guinea ($5.25) per day, upwards.

The St. Ermin's Hotel is connected by a private corridor to St. James' Park subway station, whence trains run direct to the automobile exhibition at Olympia. The Cunard Steamship Company has furnished a neat baggage label for the special use of the S. A. E. members.

The party which will sail on the *Mauretania* on November 1 will include forty-three persons. Sixteen members will join the party abroad. A group photograph will be taken before the start.

Big Purses for Savannah Races

SAVANNAH, GA., Oct. 23—With the Thanksgiving race week more than a month away, interest in the approaching contests is at fever heat here. On Wednesday morning last the advance sale of box and grandstand seats for the two days' races was opened, and, in addition to 75 boxes, several hundred reserved seats in the stand were disposed of. Mayor George W. Tiedeman was accorded the privilege of buying the first box. The prices of tickets are the same as last year. Box seats for two days, $50; grandstand seats for two days, $3; general admission, $1 each day. Parking spaces will cost $25 or $50, according to location.

The large number of reservations being filed at the local hotels indicates that the crowds that will assemble here during the last week of November will exceed in size even the record-breaking gatherings of former Grand Prix weeks.

The Lozier Company has announced its intention of entering two cars in each of the big races—the Grand Prix and the Vanderbilt—but has not as yet nominated the drivers.

The prize list is growing daily. Besides the Savannah Automobile Club's $12,500 and the Remy Company's $4,250, the Findeisen & Kropf Company, maker of the Rayfield carbureter, has hung up $2,500, and the Bosch Magneto Company has come forward with cash offers aggregating $1,550.

Garford Tourists on Santa Fé Trail

OMAHA, NEB., Oct. 21—With their trip of 4,200 miles almost half completed the tourists following the "Trail to Sunset" are spending to-day in this city and Monday morning they will turn southward to strike the Santa Fé trail at Kansas City, entering on that famous highway next Wednesday to follow it over 800 miles into the great Southwest.

The four Garford touring cars which are carrying the passengers as well as the "prairie schooner" which makes the fifth car of the automobile train and in which are the hand baggage and extra tire equipment have all made the trip so far in perfect condition.

The reception accorded the tourists in Iowa during the last four days of the week just closed surpassed anything they have so far experienced. From Davenport to Omaha they followed the "River to River Road," a smooth, straight highway on which the Hawkeye motorists have been laboring for months. The tourists crossed the Mississippi at Davenport Tuesday night.

Next Sunday's stop will be at Dodge City, Kan. As towns of any size and consequently hotels of the better class are far apart in that part of the country the longest single day's run of the whole tour will be made next Saturday. This will be from Hutchinson to Dodge City, a distance of approximately 154 miles, the stop for lunch probably being made at Larned.

When the tour reaches Hutchinson, Kan., next Friday afternoon, it will have covered exactly half of the 4,200 miles of its schedule.

Floral Parade Features Lincoln's German Day

LINCOLN, NEB., Oct. 23—One of the features of the German day celebration here was an automobile floral parade, in which fifty beautifully decorated automobiles took part. The parade brought a large number of people from out of the city, being something new here.

The first prize was won by Miller & Paine, the car being decorated in brown and red autumn leaves, four gilt pillars supporting a canopy, above which in a lotus flower was a little girl. Mrs. Gillen and Mrs. Boney won second prize with a car decorated in roses and green leaves. Above the tonneau a rose arbor was erected, lattice work being covered with rose buds.

S. S. Shean took third with a simple gold and white car. H. E. Kooch, fourth, and O. E. Houck, fifth.

The Elks were awarded first prize in the lodge contest, the car being decorated with chrysanthemums on a white background, and having two elks at rest with a third standing.

The Eagles took second for lodges, with red, green and white decorations, eagles on brackets ahead of car, large white eagle above, with group of birds just over windshield.

To Fight Alabama's New Automobile Law

MONTGOMERY, ALA., Oct. 21—The new automobile law of Alabama will be attacked. The allegation is that the law is unconstitutional and the State may be forced to return the license fees collected from the owners of automobiles.

In the act there is a provision that the fee or license collected shall be in lieu of all other privilege licenses which may be exacted by any municipality or county, and the allegation is that this is in direct conflict with the Constitution of Alabama.

As the automobile law now is, the license fee is paid over to the State and a municipality or county cannot impose a tax or license, but the State divides up with the different municipalities and counties.

The flaw was picked out by R. G. Arrinton, an attorney of Montgomery, and also a well-known automobile enthusiast. It is probable that steps will be taken at once that will place the case before the Supreme Court so that a decision can be rendered before time to collect the auto tax for next year.

The legality of the law affects many owners of automobiles in Alabama. At the present time a tax is being collected by the Secretary of State and each machine is numbered consecutively.

Velie Officials Entertain Dealers

MOLINE, ILL., Oct. 23—Officials of the Velie Motor Vehicle Company were hosts last week to forty-five representatives of the Velie throughout the country who were called into the home plant to inspect 1912 models and have improvements and new conditions pointed out. The visiting dealers were addressed by Chief Engineer C. B. Rose, Sales Manager C. H. Lloyd and Assistant Sales Manager C. P. Hatter. The following officers and employees of the Velie plant entertained the visitors: President, W. L. Velie; secretary, L. M. Fuller; chief engineer, C. B. Rose; sales manager, C. H. Lloyd; assistant sales manager, C. P. Hatter; Henry T. Wheelock, in charge of truck sales; Messrs. Bryant Thompson, Brink, Soner, Ramsay, Kennedy, Froelich and Ward.

The following are the dealers registered: Messrs. Taylor, Memphis, Tenn.; Scouten, Nashville; Elliott, Nashville; Banta, Spokane; Duc Luce, Chicago; Beharall, Lowell, Mass.; Wylie, Kansas City; Johnson, Essex, Vt.; Bornstein, Boston; Lane, Cormley and Steinert, Pittsburgh; Morse, Knoxville; Glynn, San Francisco; Benton, Los Angeles; Dixon, Buffalo; Davis David, Philadelphia; Garland, New York City; Kerr, Syracuse, N. Y.; Schmidt, Harrisburg, Pa.; Varrell, Gloversville, N. Y.; Burns, St. Louis; Wetherby, Syracuse; Reed, Wichita, Kan.; Marrill, Louisville, Ky.; Lindsay, Omaha; Snell, Attleboro, Mass.; Geer, Minn.; Smith, Hibbing, Minn.; Titus, Miles City, Mont.; Harrington, Sleighton; Roller, St. Paul; Highshoe, McLean; Hogan, Alvedo, Ill.; Heiserman, Albia, Ia.; Ketchan, Farmington; Kelly, Farmington; Minturn, Winterset, Ia.; De Jarnette, Omaha; Randall, Oklahoma City.

News of the Week in Detroit

DETROIT, MICH., Oct. 23—The activity that prevailed in Detroit factories earlier in the month continues, with no sign of abatement. Many of the plants are working both day and night shifts and still are behind orders in some instances. So there is every reason to believe that the business for the month will meet all expectations.

The Chalmers Motor Company is planning the erection of a new warehouse at its plant in the very near future. It will be so arranged that cars can be loaded for shipment directly from the warehouse. The plant is running full capacity.

The Chalmers annual technical convention began last week, with a good attendance. The convention will be held in three divisions, the second division convening to-day and the third, Oct. 30. Those in attendance last week included technical men from the Eastern cities and from Michigan, Ohio and Indiana. Nearly an entire day was spent in dissembling and studying the chassis of the Chalmers "36." Talks were given by George W. Dunham, vice-president and consulting engineer of the company; A. B. Hanson and R. O. Gill, of the service division, and C. C. Cross, head of the inspection department. Particular attention was given to the Chalmers standardization methods. These conventions are for the benefit of representatives of the service divisions of Chalmers dealers and Chalmers road men.

Three delegations representing outside motor car manufacturers, including managers and their engineering staffs, were among the visitors to the Cadillac plant last week. They came for the express purpose of studying the Cadillac electric starting and lighting process. The Metzger Motor Car Company entertained a dozen or more dealers from various parts of the country and State during the week.

The chief topic of discussion in local motor car circles the past week has been the report of the tax commission appointed by Gov. Osborn to make an inquiry into the tax question. The report, which was made public a few days ago, confirms earlier statements to the effect that the motor industry would come in for a good deal of consideration. That an attempt will be made by the State to force the manufacturers to pay more taxes was made clear by the governor in an address before the members of the Detroit Board of Commerce at a luncheon in the Hotel Cadillac last Thursday, when he said:

"There is to my mind no good reason why those corporations of Michigan which bear inadequately their burden of taxation should not be brought to a point of correction. The automobile industry in Detroit and Michigan is one that should be aided and encouraged in every reasonable manner. But there is not one automobile manufacturer who would care to be placed in the charitable class, or who would contend that $1.40 per thousand is enough taxation, when the railroads are paying $20.55; residences in cities and villages, $14.50; farms, $10; electric railroads, power, heat, light and gas companies, $7, and manufacturing corporations, $5.30. This inequality and unfairness is intolerable."

The figures quoted by the governor were taken from the tax commission's report. With reference to the automobile industry in Michigan, the commission shows that manufacturers of motor cars and automobile parts in the State reported a total net income of $14,508,529, net income, exclusive of all interest, $13,428,053; capital stock, $29,192,079; indebtedness, $47,239,044; taxes paid in 1909, $185,000. The report goes on to say:

"The net income, exclusive of interest, capitalized at 10 per cent., gives the value of the stockholders' equities as $134,280,530 which, divided into the taxes paid for these industries, gave a rate of $1.40 on the thousand. If we add the indebtedness, the value of the corporate business is $181,000,000, which paid taxes at the rate of $1.05 per thousand, or 1.14 per cent. of the net income.

"A careful perusal of the methods employed and the results produced in these figures demonstrates the existence in Michigan of a large amount of property grossly undertaxed, as compared with other property."

In another part of its report, the commission says:

"It will be shown that too much attention has been centered on the taxation of farm property and railroads, while the automobile manufacturing industry seems to have been sadly neglected, as viewed from a taxation standpoint."

In response to many requests from various interests, the commission has arranged for public hearings on their report. These will begin at Lansing in a day or two, and it is expected that the motor car makers will be well represented.

In addition to the condemnation proceedings instituted in the recorder's court a few days ago, the Herreshoff Motor Company, which is building a factory on Woodward avenue, in a fashionable residence neighborhood, now has an injunction suit on its hands. Judge Donovan, of the Wayne circuit court, has issued an order, on the petition of several residents of the neighborhood, directing the company to show cause why an injunction should not issue.

The 3-ton Packard truck, which was brought back to Detroit a few days ago after its transcontinental run from New York to San Francisco, leaves to-day on an exhibition tour that will cover a period of several weeks. It goes first to Toledo, O. Other cities to be visited are Cleveland, Rochester, Syracuse, Albany, Boston, Providence, Hartford, Bridgeport and New York.

The United Motor Detroit Company is well pleased with the showing made by the Maxwell Messenger in its 120-hour nonstop run, which ended last Tuesday. The little 16-horsepower car covered a total of 2,060 miles, consumed 91 gallons of gasoline, an average of 22 1-2 miles per gallon; 82 pints of oil and two quarts of water.

Weather permitting, the Wolverine Automobile Club will hold the second of its under-sealed-orders sociability runs next Sunday. The Detroit *Saturday Night* offers a silver trophy to the member coming nearest to the time of the pathfinding car. The club is making arrangements for a big social evening Nov. 4. It is also planning to get out a club publication. The first number will make its appearance early next month.

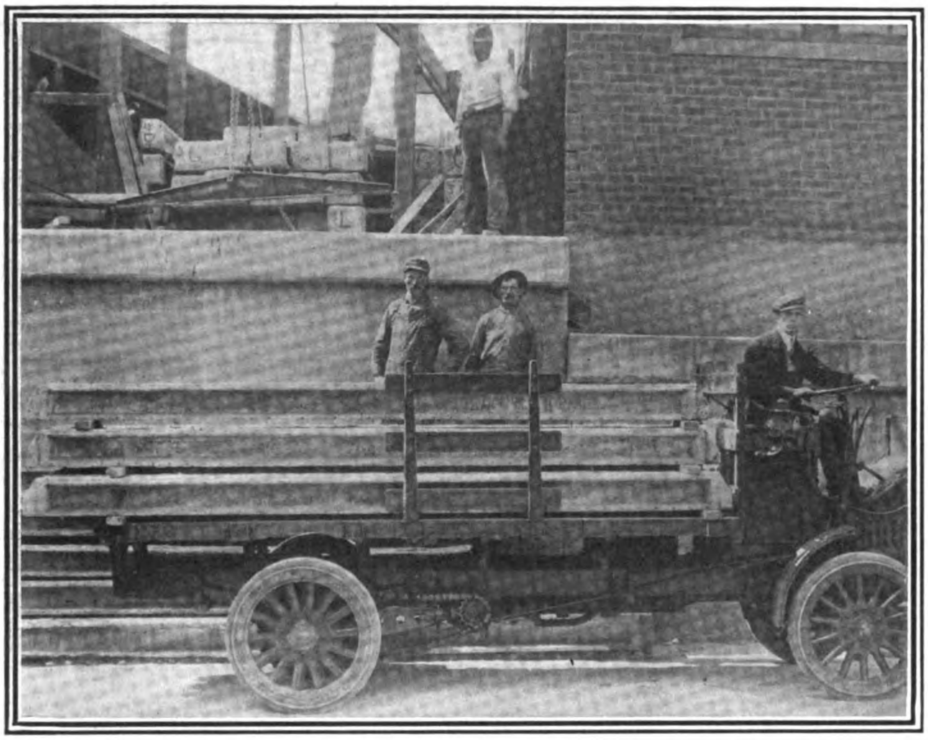
Tire Men Gather in Metropolis

An important gathering of tire men was held at the Hotel Astor in New York last Sunday, when the United States Tire Company called together all its branch managers and salesmen in the Central and Eastern Districts to discuss trade policies for the coming year. About 150 representatives of the company were present, among whom were: J. M. Gilbert, general manager; J. D. Anderson, general sales manager; A. I. Philip, manager central district; O. S. Tweedy, manager eastern district, and William MacMahon, chairman of the factory committee.

The meeting was presided over by Mr. Anderson. General Manager Gilbert made the principal address. He outlined in detail the plans of the organization for taking care of the country's demands during the coming year. Addresses also were made by Messrs. Philip, Tweedy, Anderson and MacMahon.

Following the business session a luncheon was served and the Central District managers and salesmen made a hasty getaway for their homes.

This was the first trade-policy meeting held by the United States Tire Company since its organization.



Universal 3-ton truck in the service of the Concrete Lumber Co., Detroit, Mich.

SAN FRANCISCO.—The Velie cars will hereafter be handled in Northern California by the Auto Sales Company.

SAN FRANCISCO.—The Olds Motor Works, of Lansing, Mich., has established a branch here, with D. L. Whitford as manager.

SAN FRANCISCO.—The Northern California agency for the Selden car has been placed with the Middleton Motor Car Company, of this city.

SAN FRANCISCO.—The H. O. Harrison Company, now California distributer of the Peerless and Everitt cars, has taken the agency for the Waverley Electric.

FRANKLIN, IND.—It is announced that the Whitesides Motor Truck Company, located here, has leased the buildings formerly occupied by the Safety Shredder Company at Newcastle and will move to that city.

SAN FRANCISCO.—Geo. A. Troutt, representing the Lion Motor Car Company, of Detroit, has placed the Northern California agency for the Lion with the Reliance Automobile Company, which also handles the Knox and Detroit electric lines.

SAN FRANCISCO.—G. L. Wands has been appointed director of agencies for the Haynes Auto Sales Company, Coast distributer of the Haynes and Krit cars. Chas. Corcoran takes his place as sales manager of the local Haynes branch.

SAN FRANCISCO.—The Reo Pacific Company has been appointed distributor of the Premier cars in Northern California and Nevada. Norman de Vaux, manager of the company, also takes over the Reo wholesale business in Southern California.

INDIANAPOLIS, IND.—The Central Automobile Company, North Capitol avenue, has taken the agency for the line of electric trucks manufactured by the Walker Vehicle Company, Chicago. The Indianapolis company will distribute the Walker throughout Indiana.

WILMINGTON, DEL.—The first automobile ambulance in the State has been placed in service here. It is connected with the Fire Department and is operated by No. 4 Company. The car comprises a Mitchell chassis and a body of the regulation pattern, built by the Bowe Carriage Co., of this city.

DETROIT, MICH.—Hugh Chalmers, head of the Chalmers Motor Co., will be one of the speakers for Road Users' day, which will be one of the features of the first American Road Congress, to be held in Richmond, Va., Nov. 20-24. His topic will be "The Forecast of the Automobile Industry."

SAN FRANCISCO.—The National agency for Northern California has been annexed by the Howard Automobile Company, Coast distributor of the Buick cars. Carl Christensen, hitherto representative of the National, joins the Howard forces and will remain in charge of the National end of the establishment.

SAN FRANCISCO.—The Ford Motor Company, of Detroit, has established a branch house here, to handle Northern California, Nevada and the Hawaiian Islands. The new Ford headquarters will be in a spacious building at Van Ness avenue and Fell street. The branch will be in charge of J. B. Lund, who has been assistant manager of the Ford branch in Seattle.

KANSAS CITY, MO.—At the largest and most enthusiastic meeting that has ever been held the Kansas City Motor Car Dealers' Combined Associations decided to hold a motor car show February 12 to 17.

DETROIT, MICH.—M. H. Snyder, of Bozeman, Mont., has been appointed sales manager for the Day Utility Car Co. Mr. Snyder has been a dealer in Bozeman for several years and came here last week to secure the agency for the Day car in the State of Montana.

DETROIT, MICH.—The General Motors Co. has found it necessary to seek larger quarters for its general offices and will move from its present location at No. 127 Woodward avenue to the new Boyer-Campbell Building as soon as the latter is completed, occupying practically the whole building with the exception of the ground floor.

SAN FRANCISCO.—The local branch of the American Motors Company has been incorporated as the American Motors California Company, with J. I. Handley as president. W. Scott Heywood, a wealthy oil man of California, becomes vice-president and general manager. Marc Bunnell, until now manager of the branch, becomes district sales manager for the Pacific Coast and inter-mountain States.

NEW YORK CITY—H. F. Donaldson has sold his interest in *The Commercial Vehicle* to the United Publishers Corporation, and has tendered his resignation as president and editor of that publication. Mr. Donaldson intends to join the S. A. E. party sailing for England November 1, and while abroad will investigate commercial vehicle conditions in Europe, returning in time for the New York shows in January.

SOUTH BEND, IND.—The Fisher Manufacturing Company, of South Bend, has been reorganized with capital stock of $100,000, and will locate in Toledo, Ohio. The new company will be known as the Electric Auto-Lite Company with A. W. Fisher, of South Bend, president; S. L. Kelly, South Bend, vice-president and general manager; C. O. Miniger, Toledo, secretary and treasurer. The capital stock has been fully paid in and the company expects to move to Toledo immediately.

TOLEDO, OHIO—Among the "fans" who witnessed the world's championship series between the New York Giants and Philadelphia Athletics were the Overland baseball team, composed of men employed in the Willys-Overland plant at Toledo. During the summer a Toledo newspaper conducted a contest for the most popular amateur and semi-professional baseball team in Northern Ohio, and the Overland organization received an overwhelming majority by popular vote. In addition to winning the trip East to witness the series, the Overland team received a cash prize of $500.

DETROIT, MICH.—The Warren Motor Co., of this city, has been elected a member of the Automobile Board of Trade.

INDIANAPOLIS, IND.—The Fisher-Gibson Company has become the Indiana distributor for the Stearns. This company also represents the Overland, Empire, Stoddard Dayton, Alco and Baker.

NEW YORK CITY—At the regular monthly meeting of the Motor Truck Club on Wednesday, October 25, at 6 p.m., at the Hotel Empire, Broadway and 63rd street, there was an informal dinner which was followed by the regular papers, discussion and business.

MISHAWAKA, IND.—Frank Dean, formerly connected with the Thomas Flyer Company, of Buffalo, N. Y., has been appointed superintendent of the Simplex Motor Car Company, to succeed Joseph Holloway, who has resigned.

DES MOINES, IOWA—The Herring Motor Co., of this city, Iowa agent for the Ford, this week established an agency at Waterloo. The company will be known as the Repass Automobile Company and will handle Fords exclusively.

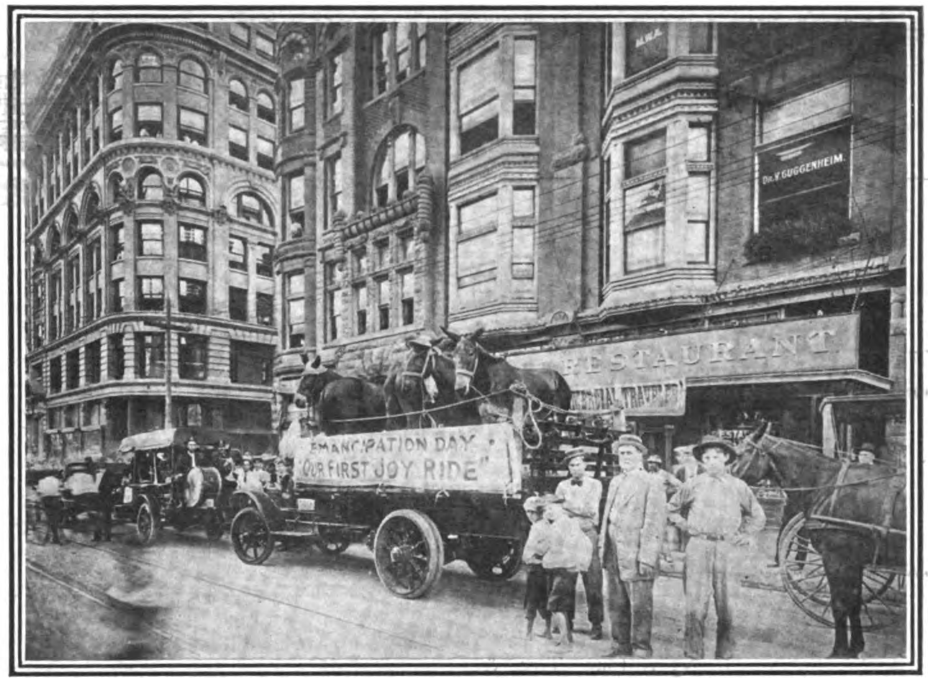
MONTGOMERY, ALA.—The Chalmers Agency has one of the best exhibits in the machinery hall of the Alabama Exposition now in progress here. It is the only local agency with a large exhibit. There are five cars shown.

NEW YORK CITY—Mr. Chas. A. Ackerman has severed his connection with the F. B. Stearns Company and has accepted a position in the sales department of S. J. Wise & Company, Eastern distributors of the Valveless Amplex car.

DES MOINES, IOWA—Frank Gotch, the world's champion heavyweight wrestler, has closed contracts with the Studebaker Corporation, to handle E-M-F and Flanders cars in Humboldt, Iowa. He also represents the Mitchell there.

INDIANAPOLIS, IND.—From January 1 to October 20 there were 2,623 motor vehicle licenses issued by the city of Indianapolis. During all of 1910 there were 1,850 licenses issued. City Controller Wallace has recommended a new ordinance amending the license fees, fixing the license for runabouts at $3, for turing cars $7 and for trucks $10. All motor vehicles, regardless of size, now pay but $3 a year.

DETROIT, MICH.—The New Departure Manufacturing Company has installed at its Western Branch, 1016 Ford Building, a measuring machine which is available without cost to the trade in general for close measuring. The machine positively indicates variations of 1-40 of .001 inch, and is a duplicate of the machine used by the company at its factory in Bristol, Conn., in accurately manufacturing gauges used for inspecting New Departure ball bearings.



Effective way in which a Texas motor truck dealer advertised his vehicles

Automobile Incorporations

AUTOMOBILES AND PARTS

BUFFALO, N. Y.—Queen City Electric Automobile Co.; capital, $50,000; to make automobiles. Incorporators: A. C. Towne, C. S. Chamberlain, Moses T. Day.

BUTLER, PA.—Carter Motor Car Corporation; capital, $50,000; to build motor cars.

CHESTERTOWN, MD.—Chestertown Automobile & Garage Co.; capital, $25,000. Incorporators: H. Benge Simmons, A. Parks Rasin, L. Bates Russell.

CHICAGO, ILL.—Karbeck Motors Co.; capital, $50,000; to build automobile engines. Incorporators: E. E. Hartman, A. T. Ewing.

CLEVELAND, OHIO.—Richardson-Neighbors Motor Co.; capital, $5,000; to sell automobiles. Incorporators: F. E. Richardson, H. F. Neighbors, W. J. Dawley.

DAYTON, OHIO.—Dayton & Troy Automobile Co.; capital, $10,000. Incorporators: C. E. Emerick, S. S. Faulkner, W. J. Sherer, S. B. Franklin, D. B. Sherer.

DAYTON, OHIO.—Marion Automobile Co.; capital, $5,000; to sell automobiles as well as accessories. Incorporators: Leslie B. Eaton, Frank W. Penebaker, O. G. Stout, William C. Frizzell, C. L. G. Breene.

DAYTON, OHIO.—Ohio Mercer Sales Co.; capital, $20,000; to buy and sell automobiles and accessories. Incorporators: Geo. A. Ware, M. E. State, F. P. Chamberlin, B. L. Hull, H. I. Robeson.

LANSING, MICH.—Mechanics Motor Car Co.; capital, $10,000; to build automobiles.

LEWISBURG, W. VA.—Greenbrier Motor Co.; capital, $10,000; to sell automobiles, etc. Incorporators: Mason Bell, F. E. Campbell, F. M. Arbuckle, K. M. Snyder, W. E. Hines.

MEMPHIS, TENN.—Noble S. Bruce Auto Co.; capital increased from $10,000 to $50,000. Incorporators: J. W. Bruce, C. E. Beloate, Noble S. Bruce, John S. Parker, C. H. Thomas.

MEMPHIS, TENN.—Chickasaw Motor Car Co.; capital, $25,000; to sell automobiles and conduct a repair business.

MONTCLAIR, N. J.—Frank A. Reeve Co.; capital, $50,000; to build motor cars. Incorporators: Frank A. Reeve, John A. Butler, David H. Slayback.

NEW YORK CITY.—Colonial Sales Co.; capital, $10,000; to deal in automobiles and accessories. Incorporators: Everett A. Levy, Louis V. Hansen, Benj. H. Stern.

NEWARK, N. J.—Merchants Motor Car Co.: capital, $500,000; to build automobiles.

PHILADELPHIA, PA.—Cavac Motor Car Co.; capital, $500,000; to build automobiles

TOLEDO, OHIO.—Ford Bros. Auto Sales Co.; to deal in second-hand automobiles. Incorporators: Guy R. Ford, J. R. Ford.

WILMINGTON, DEL.—Union Motor Car Co.; capital, $25,000; to build automobiles.

AUTOMOBILE GARAGES; ACCESSORIES

CAMDEN, N. J.—International Airless Tire Co.: capital, $100,000; to make automobile tires. Incorporators: J. H. Nixon, I. Zimmerman, T. B. Hall.

CLEVELAND, OHIO.—Start-O Co.; capital, $10,000; to make and sell starters and other accessories. Incorporators: Henry P. Beckenbach, Hubert B. Fuller, E. L. Stoiber, William E. S. Fitzgerald. R. M. Hard.

CLEVELAND, OHIO.—Moore & Rigby Garage and Sales Co.; capital, $10,000; to conduct a garage and repair business. Incorporators: W. H. Moore, John Moore, Albert V. Rigby, C. F. Magee, C. E. Alden.

DETROIT, MICH.—K. & H. Lamp Co.; capital, $12,000; to make and sell automobile lamps. Incorporators: Paul Krastin, John H. Hart.

FLOYD, VA.—American Brake Lever Co.; capital, $15,000; to manufacture brakes of all kinds. Incorporators: V. M. Sowder, R. F. Tompkins, S. R. Brame, J. M. Peterman.

HIGHMOUNT, N. Y.—Stein Tire & Rubber Co.: capital, $10,000; to make tire and rubber goods. Incorporators: Jay N. Emley, Clarence E. Mundy, John N. Scelsa.

JERSEY CITY, N. J.—Seventh Avenue Garage; capital, $25,000; to operate a garage business. Incorporators: Chas. H. Weller, Harvey B. Hall, Leo J. Cain.

KENILWORTH, N. J.—Kenilworth Rubber Works; capital, $60,000; to make automobile tires. Incorporators: Geo. B. Bradshaw, Lester F. Dittenhoefer, Edward W. Lawlor.

MARTINSVILLE, OHIO.—Clucker & Hixson Co.; capital, $2,500; to make and sell accessories. Incorporators: C. E. Westervelt, C. L. Hixson, Melcena West Hixson, W. B. Jackson, F. A. Kehrer.

NEW YORK CITY.—Senora Motor Horn Co.; capital, $50,000; to manufacture automobile supplies. Incorporators: Russell Goldman, A. Foshay, H. Neuhardt.

NEWARK, N. J.—Gray Specialty Co.; capital, $125,000; to make automobile supplies. Incorporators: Edward Gray, Edward Gray, Jr., Theo. F. N. Gray.

RACINE, WIS.—Kelly-Racine Rubber Co.; capital was increased from $500,000 to $1,000,000.

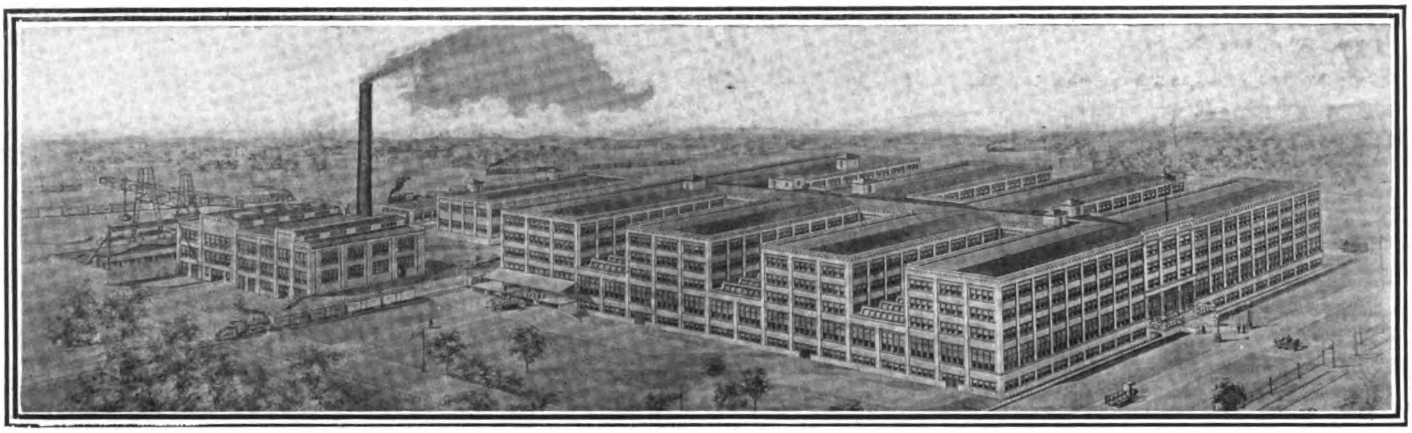
RICHMOND, VA.—Hutzler & Co.; capital, $25,000; to handle automobile supplies. Incorporators: H. C. Beattie, Sr., Jonas Marcuse, Leroy Hutzler.

SAN FRANCISCO, CAL.—Halliwell Company; capital, $50,000; to handle accessories.

VINITA, OKLA.—Vinita Automobile Co.; capital, $10,000; to deal in motor cars. Incorporators: Walter A. Cronan, M. R. Kapp.

WILMINGTON, DEL.—Lake Shore Building Co.; capital, $400,000; to operate garage.

OF INTEREST to the INDUSTRY



AKRON, O.—The magnificent new plant of the Firestone Tire & Rubber Company illustrates the wonderful growth in the automobile and tire industry. Less than a dozen years ago the company occupied a small factory employing only a score of hands. The new plant, covering many acres of ground, includes the largest tire building in the world and employs thousands of hands.

SYRACUSE, N. Y.—F. V. Coville has been appointed buyer for the H. H. Franklin Manufacturing Company, succeeding W. G. Lindsey, who resigned.

BOSTON, MASS.—The Boston branch of the Lenox Automobile Company has been moved from 16 Pleasant street to Columbus avenue.

BALTIMORE, MD.—The Goodyear Tire and Rubber Company, of Baltimore, has been conducting an exhibition of the no-rim-cut and non-skid Goodyear tire at its headquarters, 533 North Howard street.

BOSTON, MASS.—The building at 1070 Boylston street is now being remodeled and when the work is completed the Metz company will move into it from their present salesrooms on Huntington avenue.

FLINT, MICH.—After having been connected with the W. A. Patterson Company for several years, Patrick H. Doherty has resigned to become associated with Benjamin Rozensweig, Jr., in the auto parts business.

SYRACUSE, N. Y.—Bert S. Bingham, district manager in New York and Pennsylvania for the Regal Motor Car Company, has just closed a 1912 Regal contract with the Syracuse Regal Auto Company, 1205 West Genesee street.

FLINT, MICH.—Floyd A. Allen, acting assistant to General Manager Nash of the Buick Motor Company, has been promoted to the position of assistant secretary and treasurer of the company, with headquarters at the local plant.

ATLANTA, GA.—The Velie Motor Vehicle Company, of Moline, has opened a branch house at No. 247-249 Peachtree street, Atlanta, Ga., for the purpose of distributing the line of automobiles and trucks throughout the southeastern part of the United States.

LANSING, MICH.—The Olds Motor Works is to open a branch in Saginaw for the distribution of automobiles in that city and surrounding territory. William H. Watt will be in charge of the branch. The property selected is just off Jefferson avenue in Saginaw.

BALTIMORE, MD.—The latest truck to enter this field is the Federal, which is being handled by the Oakland Sales Company, representatives for the Oakland car, 107 West Mount Royal avenue. The company is the distributor for the truck in Maryland, Virginia and the District of Columbia.

JEFFERSON, WIS.—The Kenzler-Waverly Motor Co. has started work on the first unit of its new plant here, which will be a factory building, 60 x 100 feet and two stories high. The concern is a consolidation of the Waverly Mfg. Co., of Milwaukee, and the Kenzler-Waverly Co., of Cambridge, Wis.

TOLEDO, O.—The Mather Spring Co., which manufactures automobile springs, is building a handsome factory structure near the Willys-Overland plant. It will be ready for occupancy within a few weeks. The new plant covers a ground space of 80 x 400 feet and is constructed entirely of steel and brick. The working department is on the ground floor. The company is headed by Gordon Mather.

PHILADELPHIA, PA.—The Hess-Bright Manufacturing Company, makers of ball bearings, announce that they have received word from the Deutsche Waffen-und Munitionsfabriken, for whom they are importers, that the DWF have just been awarded the "Grand Premio" at the International Industrial and Trade Exhibition of Turin, this being the highest distinction.

AKRON, O.—The annual meeting of the stockholders of the Diamond Rubber Company was held October 18, when the regular 3 1-2 per cent. dividend was declared, and in addition an extra dividend of 2 1-2 per cent. Officers elected were: F. A. Hardy, president; A. H. Marks, vice-president and general manager; W. B. Miller, secretary; A. H. Noah, treasurer; Guy Norward, assistant treasurer.

NEW YORK CITY.—An increase of 60 per cent. in shipments of cars over the same month last year is shown in the September traffic report of the United States Motor Company. The outbound shipments filled 1,090 carloads of Maxwell, Stoddard-Dayton, Columbia, and Brush cars, and Sampson freight and delivery motors. Eighty-five railroads shared in carrying this record breaking tonnage to all corners of the world.

TOLEDO, O.—The Champion Spark Plug Co. this week purchased from the Irving B. Heiett Co. a 1 1-2-acre building site on the Lake Shore railway tracks at Upton and Avondale avenues. Work will be started immediately on a new and modern fire-proof plant of the Monitor type, the building to be 102 x 72 feet. Robert Stranahan is president of the company, which came to Toledo from Boston a year ago.

MILWAUKEE, WIS.—The Yale Mfg. & Sales Co., Manufacturers' Home building, Milwaukee, manufacturing motor car signals and accessories, has purchased the entire plant of the defunct Oostburg Foundry Co., of Oostburg, Wis., and will in the future concentrate its manufacturing activities at Oostburg, the sales and executive offices remaining in Milwaukee. The Oostburg plant is one of the most complete in the northwest and ideal for the purpose.

PATENTS GONE TO ISSUE

BLOW-TORCH—Combination of two gas outlets from separate gas vessels.

4. The blow-torch referred to in this patent (Fig. 1) comprises a cylindrical body formed with a slot in its wall and provided with concentric air and gas passages which have a common orifice, the passages communicating through an opening. Between the opening and orifice an apertured wall is placed in the air passage and means are provided for dividing the air passage between the wall and the orifice into a plurality of concentric passages. Within the air passage there is a tubular member having an apertured flange bearing against the wall. On the body is mounted a rotary sleeve rigidly connected with the tubular member mentioned which extends through the slot in the wall of the body.

No. 1,006,034—to Jacob Weintz, Cleveland, Ohio. Granted October 17, 1911; filed July 9, 1910.

ODOMETER—Milemeter in which the indicator disc is regulated by a spring.

2. The odometer consists of a wheel or disc rotatable to give a desired indication; a spring tending to bring the disc to a zero position is fixed at one end to the disc, while the other end is adapted to make shifting engagement or anchorage with fixed teeth; means for retaining the disc in any position that it is brought to and a release device operable upon the retaining means in such a way that the disc is left to the action of the spring.

No. 1,005,845—to Joseph W. Jones, New York. Granted October 17, 1911; filed August 7, 1908.

AIR-COMPRESSOR—Apparatus for condensing and cooling atmospheric air.

5. The compressor described in this patent (Fig. 2) is a combination of a power cylinder provided at one end with a connecting member adapted to deliver a fluid thereto, and an axially disposed pumping cylinder at the other end of the power cylinder. Pistons working in both cylinders are connected with one another, and means are provided for permitting the passage of fluid past the power-cylinder piston in the direction of the connecting member. The pumping cylinder is provided with inlet and outlet ports, and the power cylinder has an inlet on the opposite side of its piston from that occupied by the connector.

No. 1,005,940—to Charles Jerome Costello and Stephen Guion Skinner, Chicago, Ill. Granted October 17, 1911; filed January, 23, 1911.

CRANKING DEVICE—A system of engine starting by means of compressed air.

1. This patent relates to an engine starter as the one shown in Fig. 3, which is operatively connected with one end of the crankshaft. The rotary device communicates with an air-storage tank, containing compressed air, by means of a plurality of air passages, valves being used to control the flow of air in these passages, the valves being operated by a hand lever and mechanism adapted to close and open these valves. An air passage between the passages above mentioned leads to the connection between the rotary device and the engine shaft.

No. 1,006,063—to John S. Clarke, East Cleveland, Ohio. Granted October 17, 1911; filed July 1, 1910.

DRIVE FOR AUTOMOBILES—Transmission of power to wheels through two driveshafts.

The manner of driving two wheels (Fig. 4) is the subject of this patent, which covers the combination of a frame supported on these wheels with driveshafts, one being geared to each wheel, the shafts converging toward a point at a distance horizontally from the axis of the wheels mentioned. At the point of convergence a balance gear is mounted on the frame and it is adapted to rotate the shafts and permit independent motion of the shafts, which, together with the gearing, are enclosed in casings secured to the driving wheels, converging toward each other and united at their adjacent ends.

No. 1,005,863—to William M. Miggett, Ann Arbor, Mich. Granted October 17, 1911; filed December 31, 1909.

INTERNAL COMBUSTION ENGINE—Engine of the rotary-valve type, the valve having a main and an auxiliary port.

5. The illustration (Fig. 5) is of an internal combustion motor with a working cylinder having main intake and exhaust ports, and a valve mechanism controlling these ports including a rotary valve, having a main port adapted to register with the exhaust port, and also an auxiliary port at an angle to the main port. Means are provided for rotating the valve from the crankshaft, and for shifting the valve to bring the auxiliary port into operation.

No. 1,006,095—to Russell Huff, Detroit, Mich. Granted October 17, 1911; filed May 11, 1911.

RUNNING-GEAR—System of chassis suspension.

1. The patent refers to a running-gear, front and rear axles, a reach connecting them which has rear hounds, the axle comprising substantially flat elongated bars having L-shaped ends, one secured above and one below on the rear end of the reach and the hound, stub axles having bodies arranged between the L-shaped ends, bolts penetrating the L-shaped ends and the bodies, the bolts being extended upwardly, thus affording means for holding a wagon body in place, wheels for the front axles and stub axles, and connections between the bodies of the stub axle and the front axle to cause them to oscillate in unison.

No. 1,005,909—to Fleming H. Weaver, Griffin, Ga. Granted October 17, 1911; filed April 29, 1911.

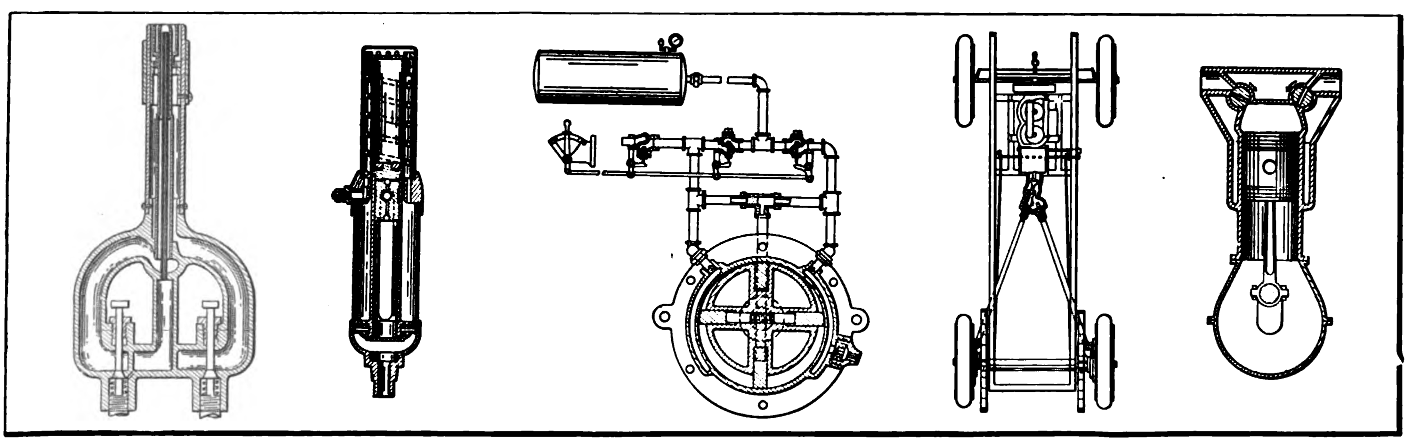


Fig. 1—Weintz blow-torch. Fig. 2—Costello-Skinner air compressor. Fig. 3—Clarke cranking device. Fig. 4—Miggett drive. Fig. 5—Huff engine

Newest Ideas Among the Accessories

Neverout Radiator Heater

THE Neverout Radiator, Figs. 1 and 2, is made with the object of keeping the circulating water in the piping system of an automobile warm and in circulation, while the motor is not working, and the car, in a good many cases, standing in a cool place. The garage type of heater is seen in Fig. 1, where it is temporarily attached to the radiator, by hooking the

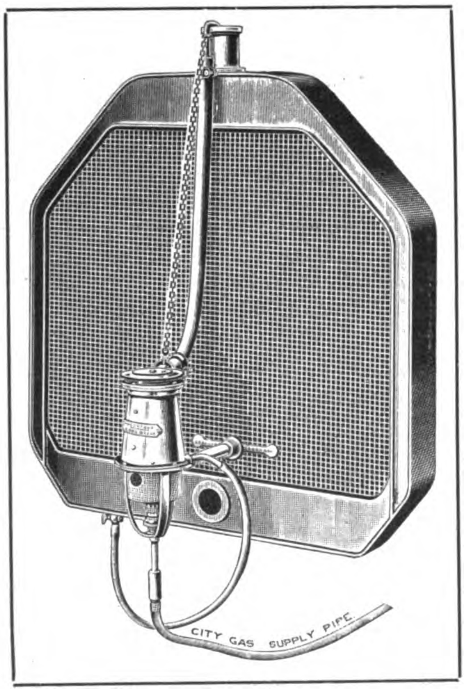

Fig. 1—Neverout radiator heater, garage type

apparatus on to the filler hole, after removing the radiator cap. The bracket of the device is made to bear against the face of the radiator, while one tube is used to connect the heater to the petcock of the radiator, and the other to permit of feeding city gas to the burner contained in the heater. After opening the petcock and lighting the burner, the water which flows to the heater, or boiler, as it might be called, is rapidly heated and raised to the height of the filler cap, thus keeping up the circulating of the water.

The original type of the Neverout heater is shown in Fig. 2, where it is permanently attached to the radiator. The burner of this type burns acetylene gas and is connected to the tank by means of a rubber tube. This type of heater is a double-walled cylinder of about 4 inches in length with cross-staggered copper tubes connecting the walls, around and between which the acetylene gas passes. The flame is produced on a burner resembling the Bunsen type, and the oxy-acetylene flame has a temperature of about 3,000 degrees at the tip of the inner cone. The double-walled jacket has a connection passing from its upper end through the lateral air space of the radiator and communicating by a concealed 1-4-inch copper tube with the upper radiator portion. The lower portion of the jacket is connected to the lower radiator regions in a similar way. This device is effective in keeping up the circulation in the cooling system with the power shut off, and it is claimed that by turning the flame to its maximum size the water in the piping may be made to boil.

The device uses about four times as much oxygen as it does acetylene, and under normal conditions it burns only about half a cubic foot of gas per hour, so that it is very inexpensive. At all events, this means of keeping the water warm is less expensive to keep the engine running, perhaps for a half hour or longer, only to avoid freezing of the cooling water.

The Neverout heater is manufactured by the Rose Manufacturing Company, 917 Arch street, Philadelphia, Pa.

Aviator Goggles

The aviator type of goggles is illustreated in Fig. 3. It is constructed with the idea to afford the eyes of the motorist a thorough and efficient ventilation. This is necessary, as otherwise vapor will accumulate on the inside of the goggle glass plates and obstruct the view of the automobilist as well as his well-being, so far as his eyes and their functioning are concerned. The body of the goggles is made of soft rubber, into which the oculars made of plate glass, are set. The tube surrounding the plates is made with air outlets directing a constant stream of cool air against the glass plates if air is permitted

Fig. 3—The Aviator goggles ventilate the eyes

to enter the tubes. This takes place through the medium of the air inlet which is of funnel shape and placed upon the communicating portion of the goggles between the two ocular portions. When the motorcar is in motion, the air striking the funnel-shaped rubber mouth is caught in the same and led through the rubber tubing to the outlets whence it flows to the inside of the goggle space. After sweeping over the glass plates the air passes out through vents opposite the ones through which it came in, and after passing through part of the rubber tubing, leaves it at the right and left sides of the respective eyes. By ventilating the inner goggle space, the eyes are enabled to continue in giving off their surplus of moisture. If this process is restrained, the comfort of the eyes as well as their working capacity is impaired.

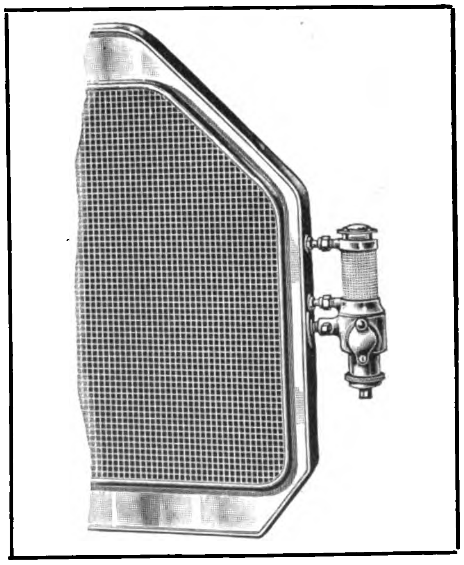

Fig. 2—Permanent type of Neverout radiator heater

The Aviator goggles, which are of a French make, are handled on this side by the W. C. P. Supply House, 1739 Broadway, New York City.

Buckeye Electric Drill

The Buckeye type of drill is a portable breast drill of convenient shape, to which has been adapted an electric motor drive. The motor has been given particular attention to make it both efficient and light. It is wound for either alternating or direct current, as well as a combination winding which will enable it to be operated on the same voltage in either alternating or direct current. The latter winding, however, is not recommended, unless it be a necessity. The drill is reversible by manipulating the motor, so that when the drill breaks it is possible to prevent more serious damage by reversing the motor. Besides being used for drilling, this instrument is adapted to tapping. The spindle is brought into locking position by means of a special patented spindle lock. The weight of the entire outfit complete with cord and socket is 12 1-2 pounds. Capacity, zero to 3-8 inches. The drill is made by the American Foundry Company, Leipsic, Ohio.

VOL. XXV NEW YORK—THURSDAY, NOVEMBER 2, 1911—CHICAGO No. 18

THE AUTOMOBILE

Comfort in Winter Driving

Zero weather has no terrors en tour for the lady equipped like this

SPECIAL clothing to make possible the full enjoyment of automobiling costs in the neighborhood of $50 a year for each individual motorist. Outfits of a certain character can be had for less and they may cost almost any amount more, but the average expenditure is about the figure cited.

If there are 450,000 pleasure automobiles in operation in the United States, and if there are three persons associated with each car, the aggregate cost of clothing per annum for automobiling would reach the astonishing total of $18,000,000.

In Winter, and in fact in both Spring and Autumn, comfortably warm clothing is almost as essential to automobiling as the car itself. Nothing could be more disagreeable than a long ride on a cold day where the lack of warm clothing makes itself apparent in chilled bodies and shivering nerves. On the other hand, a ride even over frozen roads and against a nipping wind is a magnificent pleasure if proper preparations for it have been made in the way of clothing.

Some of the characteristic lines of clothing that are being shown this season include the following: Caps, hoods, bonnets, polo-coats, fur coats, leather-lined fur coats, cloth coats, waterproofs, slip-overs, ponchos, gaberdines, spring pants, scarfs, gloves, muffs for hands and feet, boots, robes, puttees and leggings.

Taking these in the order given, the line of caps shown this season is limited to three types of cloth caps and two types of fur caps. Perhaps the most popular of these is what is known as the double-snap tourist. It is made in a variety of materials, silk-lined, and its distinguishing feature is in the ear-tabs which are fastened on top of the cap when it is not being used on a very cold day. The tabs look like a part of the crown except when they are in use, but when they are in action they pull down to the collar and fasten under the chin, thus making a very warm, compact bit of headgear.

The English golf cap is also exceedingly popular and differs from the double-snap cap in that it has no ear-tabs. The ears are protected by a strip of cloth that may be pulled down from a telescoped position outside the body of the cap. A variation of the golf cap is the English automobile cap. This is made on the same lines, but the part that pulls down over the ears when

The Shetland wool muffler often proves a real comforter

Knitted hoods like this add piquancy to beauty in the car

required is made either of cloth or fur. In cost the golf caps are about the same as the tourists.

For those who wish something different there are high band tourist caps and gentlemen's driving hats. The first of these is not new this season and the second is a peculiarly rakish appearing hat, with the back of the rim flattened against the crown and the peak extended and pulled down over the eyes. These hats sell for from $2.50 to $3.

In the line of fur caps there are two chief styles. The first is known as the Detroit and consists of a round crown, fitting snugly against the head. The rim is divided to form a peak that can be pulled down over the forehead and the rest of the rim can be turned down to form a warm comfortable protection for the neck and ears. These caps are made in all kinds of fur, and one variation may be noted in the fact that patent leather peaks may be had in place of the skin.

The other type of fur cap is the Alexis, a brimless, fedora shape such as is popular in Russia. The Alexis has an adjustable band that may be pulled down to ward off inclement weather. Persian lamb is the favorite material for this style. Fur caps may be had at any price between $2.50 and $30, the material ranging all the way from dog to sealskin.

When Miladi goes a-touring and the attack of Jack Frost is sharp and insistent there are many items in the grand total of automobile clothing that are in demand. Knitted hoods, varying all the way from the dainty little head covers something like those her Grandmamma used to manufacture while the dancing light from the open fire glinted from the moving needles, to the ultra-modern aviation hood that is the final word in this line, have been prepared for her comfort. Both hoods and aviation caps are made in a wealth of color, ranging from demure gray with white lace and a ruffle over her eyes to the gaily fashioned and tufted contraption that she affects when taking a short biplane ride or its equivalent in the automobile. An improvement over last year is the silk lining to keep out the wind. She can pay from $1.50 to $5 for these styles and look bewitching in either.

In the line of bonnets the field is wide. There is one confection now being displayed that will undoubtedly have a considerable vogue this season. This is a little flat, close-fitting bonnet classified as a poke. It is made of strengthened silk or taffeta and has its veil attached. The most striking example is the one shown in coronation purple. This color, by the way, is exceedingly popular and will be used extensively during the Winter. There are also poke bonnets made up in black that look just enough like widow's bonnets to be fascinating and yet carry some little dash of color to show that they are not sure-enough mourning. These cost from $5 to $15.

Fur caps in several styles will be used extensively, the Beauty being a leader. This is a round type of cap with peak and sides that turn up or down according to the desire of the wearer. They sell from $8 to $25, and are made of every conceivable kind of fur. The beaver skin makes a striking cap of this variety.

The most popular style of coat for men and women this season is made either of fur or cloth with combination collar. When the combination is off the best coat looks like any other full cut overcoat with rolling collar and revers, but when it is desired to use the combination the wearer may button the left lapel under the right side of the collar. Then by turning up an inch of the back of the collar and catching the opening together with a heavy hook and eye, the coat gives the impression of one of those trim, smooth military affairs. They come in all sorts of materials and in the polo-coat type range from $18 to $50 in price.

Furs costing from $50 to $1000, the latter being for very choice specimens of rich skins and the former representing a good

The Detroit style of fur cap is popular in cold weather

How the back turns down to keep off cold winds from the neck general average price, will be seen very generally. These are made of wallaby, coon, calf, dog, Japanese cat, civet, leopard, marmot, muskrat, beaver and a dozen other varieties.

All the coats made of fur and most of those constructed of cloth and designed for use in exposed parts of the car are fitted with wrist windshields. These are in effect woolen wristlets fastened into each sleeve so that when the wearer slips into the coat his hands will pass through the wristlets, and no matter how sharply the wind may blow his arms will not become chilled.

Last year a line of coats was displayed with a permanent leather lining throughout. The leather was of flexible texture and proved to be advantageous in very cold weather. This year a slight modification of this style has been made. The leather lining is made entirely separate from the coat itself, and is designed so that it may be worn with any kind of outer garment. In effect it is a close-fitting garment of leather that may be slipped on in excessively cold weather and left off in moderate temperature.

Such leather garments as described can be had at $35. They may be used with either cloth or fur overcoats.

In the line of waterproofs too much emphasis cannot be given. A waterproof garment of some kind is absolutely necessary to automobiling in variable weather, even if it is only a slicker or an oilskin. The slip-over type of raincoat has been popular for several years. This garment is made of pure rubber and is light and easily carried. As its name suggests, it slips over the head and laces up at the neck. It covers the whole body. It costs around $5. The poncho type is newer. It is made of heavily rubberized cloth, and the neck is fitted with a yoke of pure rubber that fits snugly after it is drawn on over the head. The poncho type sells for $7.50 to $10. There are also rubberized coats that cost $15 up and look almost like an ordinary overcoat, and there are lines of cravenettes of various styles and types that are familiar. In fact, all the overcoats made especially for automobilists are cravenetted to keep out wind and rain. The English gaberdine coat, with military collar made with a velvet band, is a trim-looking, comfortable garment.

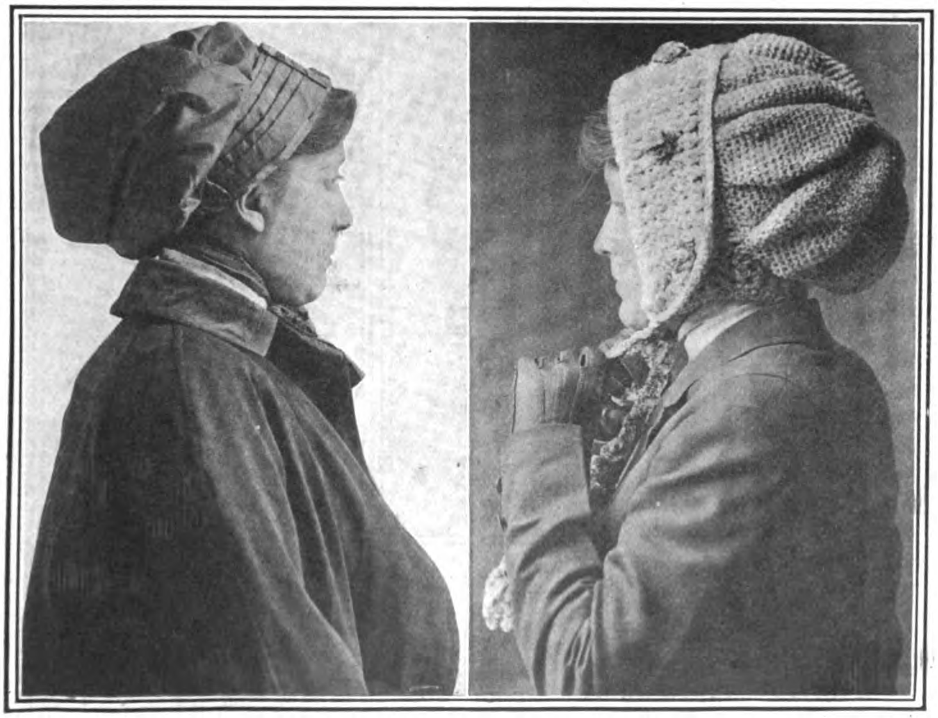
One of the unique features of the season is a device called spring pants, just plain pants. In the final analysis they consist of five steel springs, made in circular shape but open at one side. The top spring is larger than the others and is designed to open and snap close around the waist. The two medium-sized springs perform the same service about the knees and the little ones grasp the ankles. Draped from the big spring to the little ones is a covering of waterproof cloth. When the driver adjusts the spring pants he snaps the waist spring around his body and the knee and ankle springs around his legs, covering himself with an impermeable layer of waterproof which will defy the elements. The spring pants are made not only in plain waterproof cloth, but also in all kinds of fur. In their simplest form they cost $5 a pair, and they may run up to $100, depending on the kind of fur desired.

Even the little details of comfort are provided for to-day and one finds a complete line of soft, woolen scarfs for the neck. These cost from $2 to $4.50, and the best examples shown are made of Shetland wool imported for the purpose.

It has been said that if the hands and feet are warm, the whole body will be comfortable, and so the provision for gloves and boots in going on a trip in cold weather is among the most important.

Gloves for use in the car ought to be warm and the prevailing styles offered to the public are fleece-lined or fur-lined. For the driver they are gauntleted and lined, and for the lady passenger they are daintily shaped as a dress glove. They are made of every kind of glove fabric and leather, and cost from $250 to $25 a pair. There is no difference between the prevailing styles of automobile gloves and those

Two views of the popular and serviceable type of cap for automobile wear. The protective flap can be pulled down in a moment



Miladi looks charming either in silk bonnet or woolen hood, particularly if she is protected by ample wet weather garb such as these

The slip-on cover is a Godsend in the rain

that have been perfectly familiar to the outdoor winter public for years, except that the automobile gloves are warmer and more flexible.

Ordinary shoes are generally used in the car both Summer and Winter, and much discomfort is experienced thereby. Of course they will still do if proper precautions have been made to protect the feet with robes or muffs or something of that sort. But if one wants solid comfort in the coldest weather, fleece-lined boots will prove a revelation. These are made of pliable leather and are either 6, 8 or 10 inches high, opening on the side and fastening with straps. These answer the question perfectly and cost from $8 to $13.50 a pair. They are also made in hip sizes for $25.

The driver in wide cut gaberdine for moderate weather

One might ask why a lady possessing a fine muff should need special equipment of that sort for automobiling. The answer is: bad weather. A Russian sable muff probably would keep her hands warm, but she would have to be a stoic indeed if she could enjoy a trip through the rain in which the valuable muff was deluged with water. To fill this gap the purveyors to automobile comfort have prepared a leather-covered, fleece and down-lined muff that will defy the elements that sells for $8 and $10. In the line of foot protection there is the foot muff, made to lie on the floor of the car and large enough to contain a pair of feet. They are made of dog or coon skin and are said to be quite durable and very comfortable. They cost from $5 to $8.50.

Robes are not strictly clothing, but nevertheless they are important on an automobile trip. Fur robes of very high price are not so popular as they have been in the past. It has been found that the percentage of loss by thievery in the matter of fur robes is unduly large, and therefore the automobile owners are hesitating about equipping their cars with such expensive portable stuff. In the place of the magnificent fur robes that are still to be seen in appreciable number the automobilists are turning to the cloth robe interlined with pure rubber. These only cost from $10 to $17.50 and serve every purpose of the more costly robes. They are slashed to allow the hands to be pushed inside, and some of them are made to serve as foot muffs as well as protection for the legs and lap.

Puttees and leggins are not quite so lively this year as they have been in the past. The yellow leather puttee has practically passed away as a factor in the automobile clothing field, and in its place has come the black leather puttee. These are made either of domestic leather or English pigskin and cost from $5 to $10 a pair. The proper caper nowadays seems to be for the automobilist to wear golf stockings and low shoes.

An extensive line of veilings is shown for the ladies. The leader of the line is a washable, dust-proof fabric of exceeding lightness. The veils come in all sorts of colors and fabrics.

Another important garment for automobiling in cold weather is the sweater. Specially woven garments of this description sell for $8.50 up. Mica hoods are still considered good by those who know. These hoods are made of crêpe de chine or China silk and cover the whole head and shoulders. A plate of mica is inserted in an opening in the fabric so as to allow the wearer to see.

Regular suits, cravenetted for automobiling, but in other respects like ordinary clothing, cost from $17.50 to $50.

No special underwear and stockings are needed in automobiling if proper outer garments are prepared.

The man who essays to drive in his business suit, costing, say, $60, will probably pay more for his automobile clothing in the course of a year than the man who has special clothing for the purpose. Just a little lubricating oil will put a good suit of clothes out of commission, and a brake lever has been known to destroy a $40 coat in the twinkling of an eye. Hinges on the doors of the car are frequently destructive of good clothing.

Leather linings suitable for any kind of overcoat

The man who spends $50 a year to be comfortable in his car through the medium of automobile clothing will probably have more money at the end of five years than the owner who economizes in this

Cold will have only a good effect upon the driver so equipped respect and spoils his regular clothes. It is absolutely certain that he will have more comfort during the five years.

A typical man's outfit for automobiling might include the following items: Cap, $2.50; coat, $50; slip-on, $6; gloves, $7.50; suit of clothes, $40; boots, $8. Total, $114. By making renewals when needed the average cost per year for this outfit need not exceed $50.

But he will have to dig a little deeper in outfitting Miladi. Something as follows: Bonnet, $15; cap, $3.50; hat, $7.50; coat, $50; raincoat, $12; gloves, $6; muff, $8; foot-muff, $5. Total, $107.

Of course he may wish to do the thing economically, and then it is possible to cut down several of the items so as to bring the initial cost to about $85.

On the other hand, if comfort is the object and money is not, the outfit may run up to $1000 or more with great facility. To illustrate this phase of the situation it may be related that several outfits purchased this Fall in New York have totaled $2000 each and did not seem to be particularly elaborate at that. On the other hand, a very simple, comfortable outfit is within the financial limits of every man who owns an automobile.

Parsimony as far as special clothing is concerned means waste as applied to ordinary clothing and certainly spells discomfort and dissatisfaction. Reasonable expenditure, on the other hand, means economy on general lines, and the pleasure that will be the result will add greatly to the enjoyment of the automobile all the year around.

This driver would do well to put on a sou'wester

Rubber coat laced at neck and protected at wrists

While the weather so far this Fall has not been particularly severe, the advantages of wearing adequate clothing while touring was never better exemplified than during the recent Glidden Tour. Out of the 273 persons who started from New York on the long grind to Florida there was not one who had not made some special provision in the way of clothing.

There were new and natty outfits containing the latest ideas in clothing and there were makeshifts of every sort and description. There were also combinations of the latest things with old, and from every viewpoint the clothing equipment of the passengers on the tour was interesting.

The new overcoats are astonishingly comfortable

Ready for a ride in any kind of weather

In large measure the professional element was well equipped. The factory drivers and crews, first of all, had adequate waterproofs. These included sou'westers of rubber, slip-ons of heavy rubber and flexible boots. The sleeves of the rubber shirts were protected with wind and weather shields and their gloves were not only waterproof, but so arranged at the sleeves that the pelting rain had no chance to find entrance to their skin.

It was found that goggles were useless in the heavy rain storms met with in Virginia and Florida and chances had to be taken in following other cars. Quite a lot of mud and gravel was flung in the faces of the tourists while speeding in the rain and there seems to be no way to obviate this difficulty except the perfectly obvious one of not driving in weather that is so bad as to eliminate all kinds of pleasure and satisfaction in traveling.

In the amateur section of the tour there was a wide difference in equipment to be observed. A number of the gentlemen drivers wore ordinary business clothing throughout. It is safe to say that all such ruined at least one suit of clothes. One Florida owner who took part said at Jacksonville that he had spoiled three suits, one of which was rendered shapeless after reaching Roanoke, another was covered with grease and oil when it became necessary for him to tighten several bolts in the base of his engine, and the third succumbed to the drenching rain within the limits of his home city. He had a heavy rubber coat, but no boots, and, as a result, he had wet feet for 3 days and caught a severe cold.

On the other hand, there were eight contestants in the amateur section of the tour who bought complete outfits of special clothing before leaving New York. These experienced a fine trip, despite its drawbacks. They had caps for dry weather, furs for cold weather, slickers and sou'westers for wet weather, boots and also provided themselves with several pairs of gloves.

The tour demonstrated the need of a supply of gloves about as well as it did any one single item. It proved that heavy buckskin gloves worn in wet weather would be of no use for a week afterward, if at all, and that the ordinary type of walking glove would last about two hours if its owner attempted to handle the wheel of a heavy car in slippery going after it had been rained upon. Good gloves of the thoroughly waterproof type were demonstrated to be of the highest importance to the man who wants to drive in the rain.

As has been intimated, the lack of some one essential part of the clothing equipment will bring about an extraordinary amount of discomfort. Take the case of the man who forgot to buy waterproof foot covering and leg covering and remembered everything else. He was quite as miserable after facing a driving rain for 1 hour as was the fellow whose rain-hood leaked at the neck. It was found that water running down one's back was not a whit more uncomfortable than water running into one's shoes.

Gloves and boots seem much more important if you are not well supplied with them and happen to be caught in rainy or cold weather

The ladies of the party, numbering twenty-seven all told, were protected in a large measure by the tops of their cars, but there were several who rode the entire distance without such protection and they showed an astonishing amount of care in selecting their outfits. Miss Marks, who drove the Columbia all the way to Jacksonville, had an equipment that was peculiarly suitable for the occasion. For dry weather she wore a leather bound cap of jaunty effect and in wet weather she donned a sou'wester that reached clear to her shoulders all around. She had two raincoats, one a light slip-on and the other a heavy slicker, and for dry weather she wore one of the new polo coats that are so much in vogue. She had boots that would defy any rain, reaching nearly to her knees, and ordinary stout shoes for ordinary driving. Her rain gloves fitted inside the sleeves of her slicker and rested against the windshield.

It is notable and a fact that her Columbia car made every control within the time limit and that she seemed to enjoy every foot of the journey.

There were several of the ladies who made no special preparation for the tour except for raincoats and veils. They had a trying trip from every viewpoint. For sheer gameness the exhibition of these ladies was remarkable. Arriving at Roanoke after a wild ride through the Blue Ridge and across numerous fords that looked like swirling rivers, they were mostly wet to the skin when their cars drew up in front of the hotel. They were stiff from holding cramped positions to avoid the rain and cold and miserable as possible. But within an hour each appeared in the lobby attired in evening costume, apparently none the worse for the wreck of clothes and the discomfort of the rainy ride.

The evening costumes were less in evidence the next night, and by the time the party reached Atlanta there was not a presentable evening dress in the whole tour.

If these ladies had taken the pains to secure touring equipment that would serve in all kinds of weather and had paid less attention to the dress of the ball-room, they would have enjoyed the trip much more. Only a certain amount of luggage can be carried in an automobile in any event, and experience proves that it should first be devoted to carrying the prime essentials to comfort. Then if there is any spare space and carrying capacity in the car it may be used for the decorative effects in dress.

Of course the Glidden Tour does not fairly represent automobile touring conditions. It was one of those things that go to prove that it is the exceptional events that have to be provided for. And in nothing does it better emphasize this particular angle than in the matter of clothing.

It would be comparatively simple to overdo the special clothing equipment for automobiling and the use of considerable judgment is required in selecting just what is needed. Too much clothing is not as bad as too little, but it presents certain inconveniences that it would be well to eliminate. Besides costing much unnecessary money,

The woolen cap that pulls down over ears and neck and is equipped with a peak is absoluted necessary unless one has furs

Fleece-lined boots, strapping snugly around the leg and gauntleted mittens so constructed as to allow the fingers play are two things that deserve attention

each additional pound carried in the car causes extra wear on tires and mechanism, and as clothing is light and bulky a few unnecessary pounds make their presence distinctly felt on a long trip.

An unopened suit case on a long automobile trip is an economic outrage in which the owner of the car, driver and passengers are all aggrieved parties and in which its owner can take no pride or satisfaction.

Therefore, as unneeded garments are a disadvantage, care should be used before the start to select only such clothing and accessories as stand a good chance of being used.

The photographs from which the illustrations for this article were made were taken by THE AUTOMOBILE staff photographer from stock loaned for the purpose by The Automobile Supply Company.

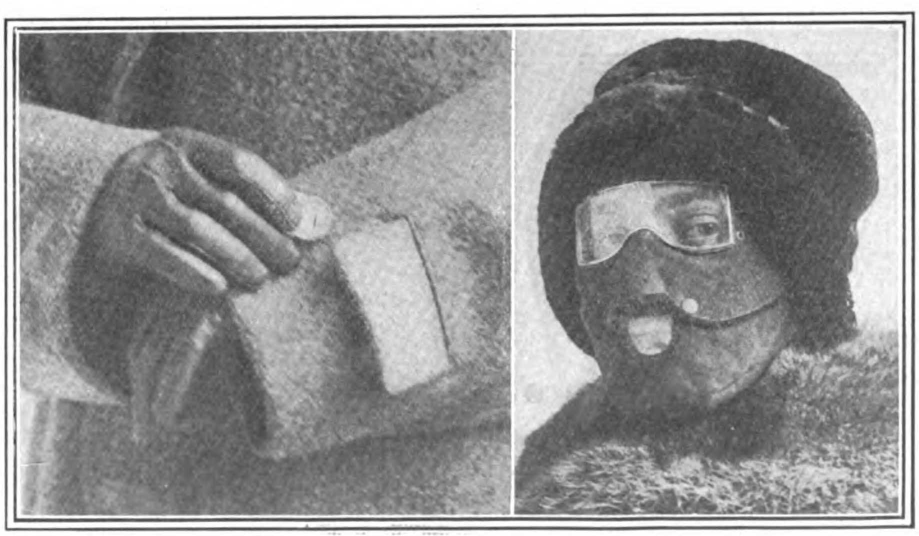
Quakers Lost Money on Fairmount

PHILADELPHIA, Oct. 30—Fred C. Dunlap, chairman of the Contest Committee of the Quaker City Motor Club, to-day submitted to Mayor Reyburn a report of the receipts and expenditures of the Fairmount Park 200-mile road race held on Monday, October 9. The statement shows that a smaller sum than usual will be turned over to the beneficiaries—in this instance the Police Pension Fund and the Fairmount Park Guard Pension Fund.

The total sum realized above expenses amounts to $3036.57, of which the first-named fund will receive $1518.29 and the Park Guards $1518.28, the money being equally divided. Originally it was the intention to include a third charity, the Children's Playground Committee to share in the general distribution of the profits, but that organization was eliminated by reason of the disappointingly small amount left after all expenses had been paid.

In detail the statement shows receipts, which embraced the sums realized from the sale of grandstand seats and parking spaces, of $8527, from which expenditures amounting to $5490.43 were deducted, leaving a profit of $3037.57 for the charity fund. The expenses incurred were larger than they ordinarily would have been by reason of the fact that the account contained an item of $1395.64 for repairing the roads in Fairmount Park, an expense that heretofore has been assumed by the municipality, but which this year devolved upon the Quaker City Motor Club to pay out of the money to be donated to charity.

The Q. C. M. C. came out of the race on the wrong side of the ledger. The actual expenses of the contest amounted to $9422.37. The club's receipts from entrance fees only footed up to $8500, leaving a deficit of $922.37.



Masks to protect the face from very cold winds and made of leather or other material with mica window, and one of the 1912 models of Arctic overcoats

Around Georgia Tour

ATLANTA, GA., Oct. 30—Owing to the complaints of Southern amateur owners who took part in the recent Glidden tour the promoters of the Tour Around Georgia, which will be run to the Savannah races, have announced most extremely liberal running conditions for their event. The top speed required will be but 18 miles an hour. It is also provided that the contestants will be allowed to run right along without using the hour allowed for the noon control. They will also be allowed to make repairs on their cars on their town time.

T. C. A. Tour's Progress

CHERAW, S. C., Oct. 30—The Atlanta-to-Richmond tour which is being conducted under the auspices of the Capitol Highway Association, the American Association for Highway Improvement, and the Chamber of Commerce of Richmond, Va., under the direction of the Touring Club of America, stopped here for luncheon. The tour left Camden this morning and will stop to-night at Pinehurst, N. C. The party expects to reach Richmond on Friday night. A Chalmers Six driven by Freeman Monroe, of Detroit, Mich., is leading the party under the command of Col. Henry MacNair, editor of the Official T. C. A. Automobile Blue Book.

Fourteen Clean Scores in Glidden

THE Maxwell factory team, entered as representing Tarrytown, N. Y., won the Glidden Trophy of 1911, scoring perfect for all three cars during the entire 11 days of running from New York to Jacksonville. Two of the cars would have been penalized for the run into Roanoke, Va., but for the ruling of Referee Walker that all cars should be allowed 26 minutes on account of delays resulting from a blockade of the road by two automobile fire engines that mired down a few miles south of Natural Bridge and held up the Glidden cars for that length of time. Despite this delay one of the cars checked in on time and the others were only 6 minutes late.

The winning was accomplished with much certainty and the cars were scientifically handled throughout. Deadly speed when unnecessary to make controls was not resorted to. There was no effort to check the team in with an hour to spare, simply to get in ahead of others. The three drivers, Walls, Gager and Costello, are experts and drove on a definite speed schedule just sufficient to make controls with an allowance for possible tire trouble and for adjustments before checking in.

The Stevens-Duryea team, representing Atlanta, was a close second in the race for the trophy. These big cars, numbers 11, 39 and 66, received a total of nineteen demerits, all of which were scored against number 66, entered by Brooks Morgan and driven by Murphy. The car was 36 minutes late in reaching Roanoke, owing to the blockade and was allowed 26 minutes under the rule, leaving it with ten points for the day. The following day it was 9 minutes late in reaching Winston-Salem. The other cars were clean throughout the running.

The same sort of a story may be told of the Jacksonville Cadillac team, which had two clean scores at the finish and one car, Number 47, penalized 23 minutes for lateness into Roanoke.

Similarly reads the story of the Ford team's showing. Car 43 suffered a broken axle out of Roanoke and was demerited 125 points. The others were clean all the way.

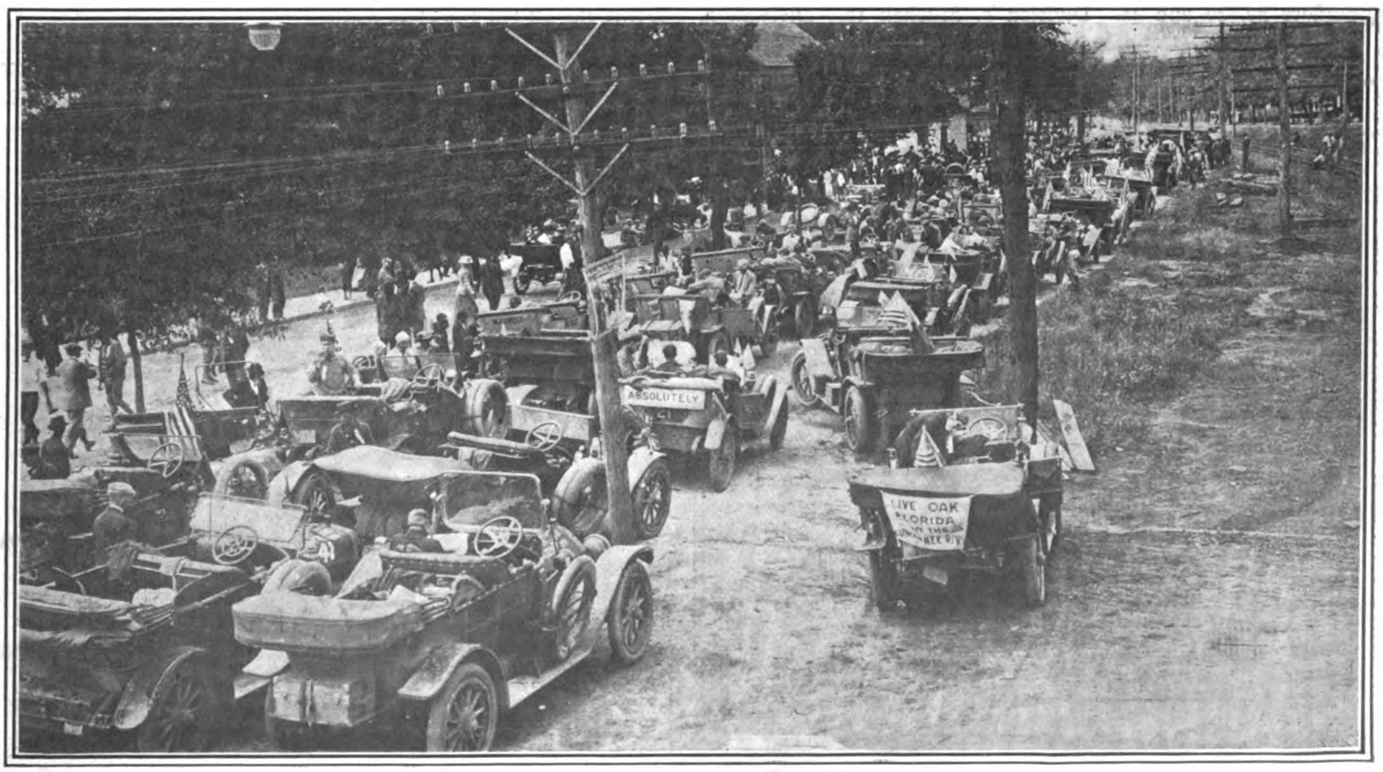
The Live Oak Cadillac team was heavily handicapped by the demerits imposed on Capt. W. J. Hillman's car. He waited for supper at Martinsville and was late in reaching Winston-Salem. The car also suffered clutch trouble at that stage of the tour. Both of the other members received penalties, No. 74 on the run into Gettysburg and No. 51 on the final day.

The Nashville Marathon team was roundly penalized on the fourth and fifth day's running and No. 57 broke spring and axle going into Jacksonville. This team, however, was the only one on the tour to make the whole distance under the power of its own engines. This happened because the three cars were the only ones that forded Back Creek without assistance. All the



Counting the contesting cars and the large escort, more than one hundred automobiles were in the line that started from Commerce

Not a little tire trouble was experienced by the contestants along that portion of the road which followed the foot of King's Mountain

others had one or more cars swamped in the raging torrent.

The Flanders factory team made a commendable showing most of the trip and one car came through with a clean score. Broken axles caused the others to be penalized.

The Metz team which had a clean score into Roanoke was overwhelmed by the run into Winston-Salem in the dark. The exceedingly rough mountain roads and the deep fords proved too much for No. 17, which broke a wheel and retired.

There were fourteen cars with clean scores at the end of the tour, namely: Maxwells 1, 2, 3 and 4, Stevens-Duryeas, 11 and 39, Cadillacs 32, 40 and 48, Fords 44 and 45, Flanders 54, Columbia 49 and Mitchell 19.

These cars drew for the Anderson, S. C., trophy, a huge silver punch bowl, and the choice fell upon Maxwell 4, the entry of Governor Hoke Smith, of Georgia.

The divisional prizes offered in each of the seven sections of Class A, consisting of $200 in each class, were won by the following. Where more than one car is named the prize was divided: Division 1, Fords 44 and 45 and Flanders 54. Division 2, Mitchell 26. Division 3, Maxwells 1, 2, 3 and 4. Division 4, Cadillacs 32, 40 and 48. Division 5, Mitchell 19. Division 6, Stevens-Duryeas 11 and 39 and Columbia 49. Division 7, American 5.

The official cars all had a rough trip. The pacemaking Cunningham was wrecked at Tifton; the Pierce-Arrow press car was smashed early in the run in Virginia; the Reo pilots experienced several accidents, one breaking a wheel and the other dislocating its propeller shaft in a North Carolina ford. The Reo truck made controls in good style and the Velie Press car was always on hand. The Chalmers Six had no trouble after the first day when it suffered a burned bearing.

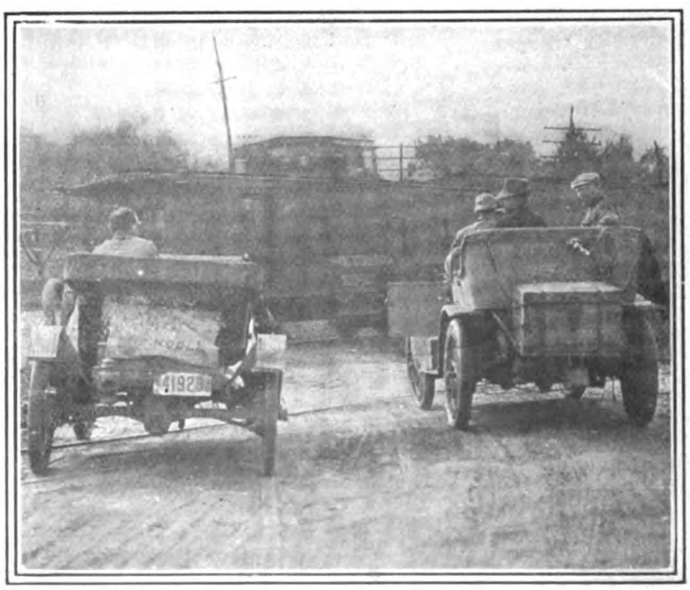
Rain Again the Last Day

JACKSONVILLE, FLA., Oct. 26—In a tropical downpour the Glidden Tour of 1911 finished its schedule here to-day after a wonderfully fast run across the dreaded sands of Florida. The start this morning from Live Oak was made at 8 o'clock and throughout the contesting column the impression was widely held that there would be no 20-mile cars to make clean scores for the day and that the chances were slim that any automobiles traveling on slower schedules than that would get through on time.

But the rain that worked such havoc in Virginia saved the day and the intermittent showers that fell in the morning aided the traction and were solely accountable for the fine showing made across the all but trackless waste.

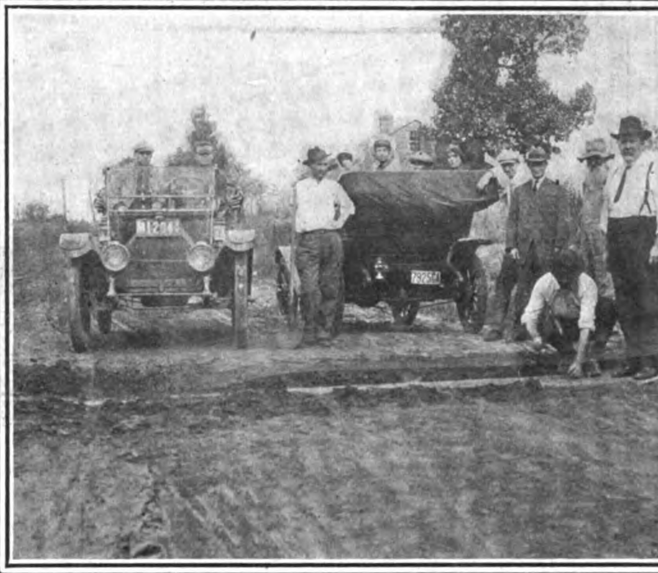
Nearing Jacksonville the rain increased in intensity and when the cars were lined up for the run into the city the rain came down solidly. It spoiled the plans for a monster reception, which fact was not without its agreeable features to the tourists in view of the trial afforded by the Atlanta reception.

Chalmers press car in the pine forests near Live Oak



Several cars were delayed by a train across the road at Spartansburg

Pilots ask directions of convict road makers below Anderson, S. C.



Waiting for road repairers to fix up a small culvert near Anderson, S. C.

The road from Live Oak was fair for a few miles and degenerated into a trail through pine barrens, winding along tortuously past swamps until Lake City was reached. The worst of the road lay between Lake City and Glen St. Mary, where the highway was meagerly marked and the sand would have been impassable at schedule time but for the hardening influence of the rain.

From Glen St. Mary to Jacksonville the road followed was a temporary trail largely built for the occasion. The building consisted in covering the softest spots with pine needles and marking the rest with confetti. The road is considered the worst in the country at its worst.

But when within 7 miles of the terminus the tourists came upon a magnificent macadam highway that will be eventually extended clear across the State.

Only two of the sixteen clean score cars that left Live Oak suffered penalties on the last day. These were American 5, which heated up in negotiating the sands, and Mitchell 73, which experienced tire trouble several times during the latter part of the run.

Otherwise the final standing of the teams and individuals was not disturbed.

The Tour Summed Up

Dripping with rain, beaten by road and weather conditions almost from the start of the run from New York, the Glidden tour rolled into Jacksonville last Thursday. With spirits drooping under the tragic happening at Tifton, there was little lightness and happiness in the column that made the long trip, covering 1,454 miles in 11 days. Sixty-four typically representative American automobiles started from New York in the contesting division and only forty-seven finished with scores good enough to receive official cognizance.

On the face of the event this was a surprising showing, but under the surface there is an excellent reason. The wonder is not that seventeen cars fell out and were penalized at least 1,000 points each, but that forty-seven finished and fourteen had clean scores.

There were three running days when road conditions could not have been worse. The run into Gettysburg was hard, but the roads encountered in Pennsylvania were fine highways in comparison with the route on both sides of Roanoke and through the sands of Florida.

As fortune would have it rain fell in a deluge upon the tour after leaving Natural Bridge, making the road tractionless where it was not bottomless. This rain extended southward and converted what were supposed to be passable roads leading well up toward the summit of the Blue Ridge into smeary imitations of toboggan slides. Six unbridged creeks, swollen and angry by the rain in the hills, added to the problem of the run into Winston-Salem. In Florida the rain was a life-saver, hardening the sands so that it was possible for the cars to get through.

The major portion of the demerits imposed came on the fourth day or later, because of it. Many of the drivers were Southerners and most of them owned their own cars. The problem presented to them by the roads in Virginia was so complex that many of them took penalties rather than try to get in on time.

When the report of Secretary Butler's death was circulated, the tourists lined up near the scene of the accident to await instructions

Line-up of the twenty-six contestants in the Long Island Automobile Club's Schimpf trophy run

Long Islanders' Secret Time Run

BROOKLYN, N. Y., Oct. 30—The contest for the Schimpf trophy, in which twenty-six members of the L. I. A. C. participated, started here on Saturday at 1 p. m. The contest was not one of skill, but one of luck rather. Before the start every contestant entered his name on a sealed envelope containing a total running time for the trip to Jamaica and return to the clubhouse. The only condition of the run was that on their way to Jamaica the tourists had to pass through Roslyn, East Norwich, Hicksville and Hempstead in the order named. Among the automobiles which took part in the pleasure run were several 1912 models.

During a dinner following the return of the "joy riders" to the club the envelopes were opened and the times demanded compared with the actual running times of the contestants. This process developed the result that Louis A. Vogel, Jr., was declared winner of the Schimpf trophy, approaching his secret time as near as 1 minute and 7 seconds. J. E. Frink, who came within 1 minute 8 seconds of the sealed time, was second, and W. H. Kouwenhoven third, with a difference of 2 minutes and 5 seconds. Several contestants experienced slight trouble with motor policemen, and it was due to the efforts of the donator of the trophy that the lawbreakers were given their liberty without considerable delay.

Forty-four in Watson Cup Contest

SYRACUSE, N. Y., Oct. 30—Ernest O. Cowan, with a Firestone-Columbus, won the second annual Watson cup run. held Wednesday. The event was under the auspices of The Automobile Club of Syracuse, and had to be postponed several times because of bad weather. It was finally held under ideal weather conditions over a beautiful scenic route approximating 100 miles, dinner being had at Cortland.

The start and finish were from the court house in this city. Forty-four cars participated and there was not a single accident, barring a few punctures. Every car finished.

Mr. Cowan's time was 4:59:15 and the secret time established was 4:56:37. S. L. Devendorf made the run in exactly 4:59, but was debarred from holding the cup for the ensuing year because he was not a member of the club. A Ford accessory truck accompanied the "parade."

Mrs. Jane M. Bartels received the cup given the woman driver coming closest to the secret time. All those participating were unanimous in pronouncing the run a complete success and it will be repeated next year.

The officials were: Starter, C. A. Benjamin; referee, H. W. Smith; pilot, B. E. Watson; manager of run, Edward Churchill. Secretary Forman Wilkinson, George E. Messer and J. F. Doane figured the time.

Some of the beauty spots encountered by the contestants in the Watson cup contest of the Automobile Club of Syracuse

Berlin's International Show

AFTER an interval of four years since the last show was held in 1907 the German automobile industry has this year again arranged a large international automobile exhibition under the auspices of the Imperial Automobile Club and the Association of Automobile Manufacturers. It was opened October 12 by Prince Henry of Prussia after a preliminary introduction of the exhibits on the previous day to the journalists of Germany and the special representatives of foreign publications.

The exposition is located in large and sumptuous quarters close to the famous Zoological Garden of Berlin and the artistic arrangements and decorations as well as the superb lighting of the approaches to the building are universally praised, especially in comparison with the earlier German exhibitions where a super-esthetic rococo style seemed to class with the mechanical nature of the exhibits. The decoration scheme for the stands has this year been made uniform for all, so far as signs, festoonings and flower pots are concerned.

View of the International Exhibition at Berlin, held under the auspices of the Imperial Automobile Club and Manufacturers

Among the exhibits a motor sleigh driven by an aeroplane propeller at the rear and steered by means of small skids in front is particularly noticed for its oddity, while a small electric three-wheeler, driving by the single wheel in front, also attracts much attention from the large majority of the visitors who do not pretend to be able to judge the mechanical refinements which form the only new features at most of the stands of the large German and foreign exhibitors. The motor sleigh, which may be noticed in the accompanying general view of one of the exhibition halls, could be intended only for arctic expeditions, as its unprotected propeller would be objectionable on any highway within the limits of civilization.

At a meeting of the Associated German Automobile Clubs on October 18, in connection with the exhibition and with the Duke of Ratibor in the chair, it was decided that there shall be no Prince Henry Cup race next year, a twelvemonth being required for formulating a set of rules and regulations for this important event, when it is resumed for 1913, which shall be found to answer the technical and sporting requirements of the day and hour. Provisions were made for the organization of a race in the Spring for small vehicles not exceeding 8-horsepower, and the Northern German Automobile Club was authorized to arrange in conjunction with a number of other clubs for a large touring expedition, without speed trials, to take place in June, the rules to be approved first by the Imperial Club.

American Wins Long Run

SAN FRANCISCO, CAL., Oct. 21.—The most severe automobile endurance run ever held in California came to a close Wednesday night when seven cars checked in at San Francisco after a run from here to Los Angeles and return, a distance of more than 1,000 miles. The penalties of each car were as follows: American "50," 87; Warren "30," 487; Flanders runabout, 857; American "50," 977; S. G. V., 1,195; Cartercar, 2,030; Flanders touring, 2,048.

Grand Prize Looms

SAVANNAH, GA., Oct. 29—Preparations for the four great road races to be given here November 27 and 30 are progressing rapidly. Within two weeks it is expected that the circuit will be ready for fast practice work and from then until the actual race days this city and the surrounding territory will be the focus of attention for the automobile world.

The course is being straightened and slightly shortened by the elimination of certain curves and turns that were present last year. The total length of the circuit will be almost exactly 17 miles, whereas before it was about 18 miles.

Turns are being banked so that it only will be necessary to shut down on two of them at the most. The engineering problems involved include lengthening and softening the angles, widening the roadway at the approaches and raising the outside edges of the course on the turns so that the chances of skidding will be minimized. In several cases crooked portions of the course have been cut out altogether by building new roads through the woods, connecting up the good stretches in satisfactory form. As a general proposition the narrow stretches have been doubled in width and the average width of the course has been increased nearly 4 feet.

From end to end the surface has been repaved and when fast practice starts the drivers will find everything in the best of condition. The course resembles in a general way the route used last year, but the improvements that were outlined in a previous issue of THE AUTOMOBILE will go a long way toward insuring safety and stimulating high speed.

So far $20,000 in round figures has been offered to the winners of the four races and before closing time it is expected that the prizes and purses usually hung up by accessory makers for winners and placed cars using their products will swell the total amount to over $30,000. The Bosch Magneto Company has offered $1550; Rayfield carbureter, $2500; Remy company, $4250, besides the purses of gold hung up by the Savannah Automobile Club, totaling $12,500.

The Vanderbilt Cup race and the contests for the Tiedeman and Savannah cups will be held November 27. The Grand Prix will be staged on November 30.

The conditions of the races are as follows: Vanderbilt Cup: Open to cars under Class C, divisions 4C and 5C that is, non-stock cars with piston displacement respectively of from 301 to 450 cubic inches and from 451 to 600 cubic inches. The conditions of Class C are that the factory shall have made at least fifty automobiles within the preceding year, not necessarily of the same model. The purpose of the rule is to bar out freak cars.

The distance of the Vanderbilt Cup race will be 289 miles, or seventeen circuits of the 17-mile course. The prize is the Vanderbilt Cup, a perpetual trophy which already has been contested for six times. The cup carries with it a cash prize to the winner of $2000 and the Donor's Trophy for permanent ownership. The entry fee is $500 for one car, $750 for a pair and $1000 for three cars, which is the limit for one make of automobile.

Until this year the Vanderbilt Cup races have been staged on Long Island over a course consisting of a portion of the Motor Parkway and country roads.

The Savannah Challenge Trophy, which includes a cash prize of $1000 and a Donor's Trophy for permanent ownership, is open to cars of Class C, Division 3C. This class includes cars having piston displacement of from 231 to 300 cubic inches, the next division below the smaller class in the Vanderbilt Cup race. The distance is thirteen laps of the 17-mile circuit. The entry fee is $250 for one car, $400 for two and $580 for three.

The Tiedeman Trophy race for the perpetual trophy of that name and a cash prize of $1000 is for cars of Class C, Division

in Near Prospect

2C, cars having a piston displacement of from 161 to 230 cubic inches. Entry fee is the same as for the Savannah cup. The distance is 170 miles or ten circuits of the course.

The Vanderbilt Cup, Savannah Cup and Tiedeman Trophy races will be run coincidentally on November 27. After they have been finished the racers will prepare for the greatest of all the free-for-all road races in the automobile world, the Grand Prize of the Automobile Club of America. Twice before has this contest been held and in each case a foreign car has borne away the honors. It has produced two of the fiercest speed battles ever witnessed and both times was won by the narrowest kind of margins.

A giant Fiat driven by Wagner won the first race and a Benz car piloted by Bruce-Brown went over the line less than 2 seconds ahead of the second car last year.

The contest is so framed as to attract the most powerful automobiles in the world, irrespective of their place of manufacture. It is free for all in a broad sense, the conditions of eligibility being extremely simple. They are as follows: No other agent of oxidation than atmospheric air is permitted. Each car must carry two persons seated side by side. Each must have a motor-driven reverse gear. Its exhaust must not be directed toward the ground. It must not be over 74 inches in width.

The entry of more than three cars of any one make will not be received and the entry fee is $1000 for one car, $1500 for two and $1750 for three.

There is no restriction as to size and power except that the cars will have to pass an examination at the hands of the Technical Committee touching their safety and that they may not measure more than 74 inches in width.

The race is to be 408 miles long or twenty-four circuits of the course, and it will be run on Thanksgiving Day. Entries for all four races close November 15.

A provision is made in the entry blank covering each contest reserving the right to the racing organizations to refuse any entry or to stage a series of elimination trials if the volume of entries should prove to be cumbersome. While the actual entries to date are few and have not been announced, it is believed that there may be as many as ninety in the four races.

In such an eventuality it is quite probable that there will have to be some form of elimination in order to make the fields small enough for safety.

So far the entries include the following (unofficially): Case 2, Fiat 5, Benz 3, Mercedes 3, Marmon 2, besides several others.

The advance sale of seats has been much greater than ever before at this stage, and preparations are being made to care for vastly larger crowds than attended last year. The hotel accommodations must of necessity be scanty, as usual, but great effort is being made to arrange for quarters for the visitors. Accommodations suitable for housing and feeding 50,000 visitors for at least four days constitute a problem of much magnitude for a city of the size of Savannah, but the committee is relying upon the Southern spirit of hospitality to come to its aid.

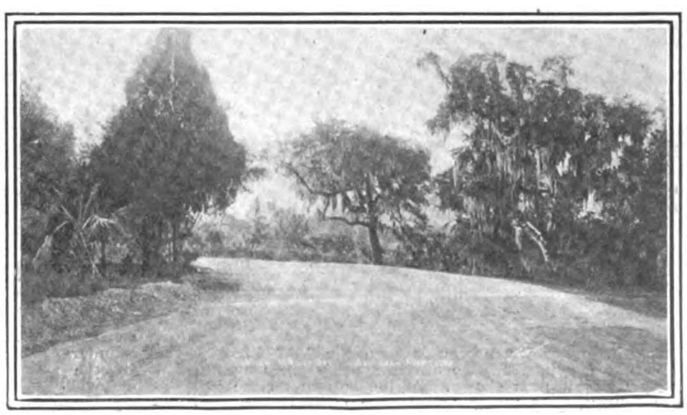
The problem presented is much more momentous than last year because of the gap that intervenes between the running of the Vanderbilt Cup and the light car races on Monday and the Grand Prix on Thursday. For a day it would be possible to camp out, carrying picnic eatables, but the idea of camping out four days in November, even in Southern Georgia, has its drawbacks.

The large hotel which will have a capacity exceeding that of any hotel existing now in the South, is not finished yet, and will hardly be so in time to accommodate the army of enthusiasts that will come to Savannah to witness the races.

5—New turn near Bona Bella, completed for this Fall's races

6—High speed will be made down Ferguson Avenue between the pines

7—The surface of the course is being repaved throughout the whole circuit



8—Another new turn, which will make La Roche avenue safer for the races

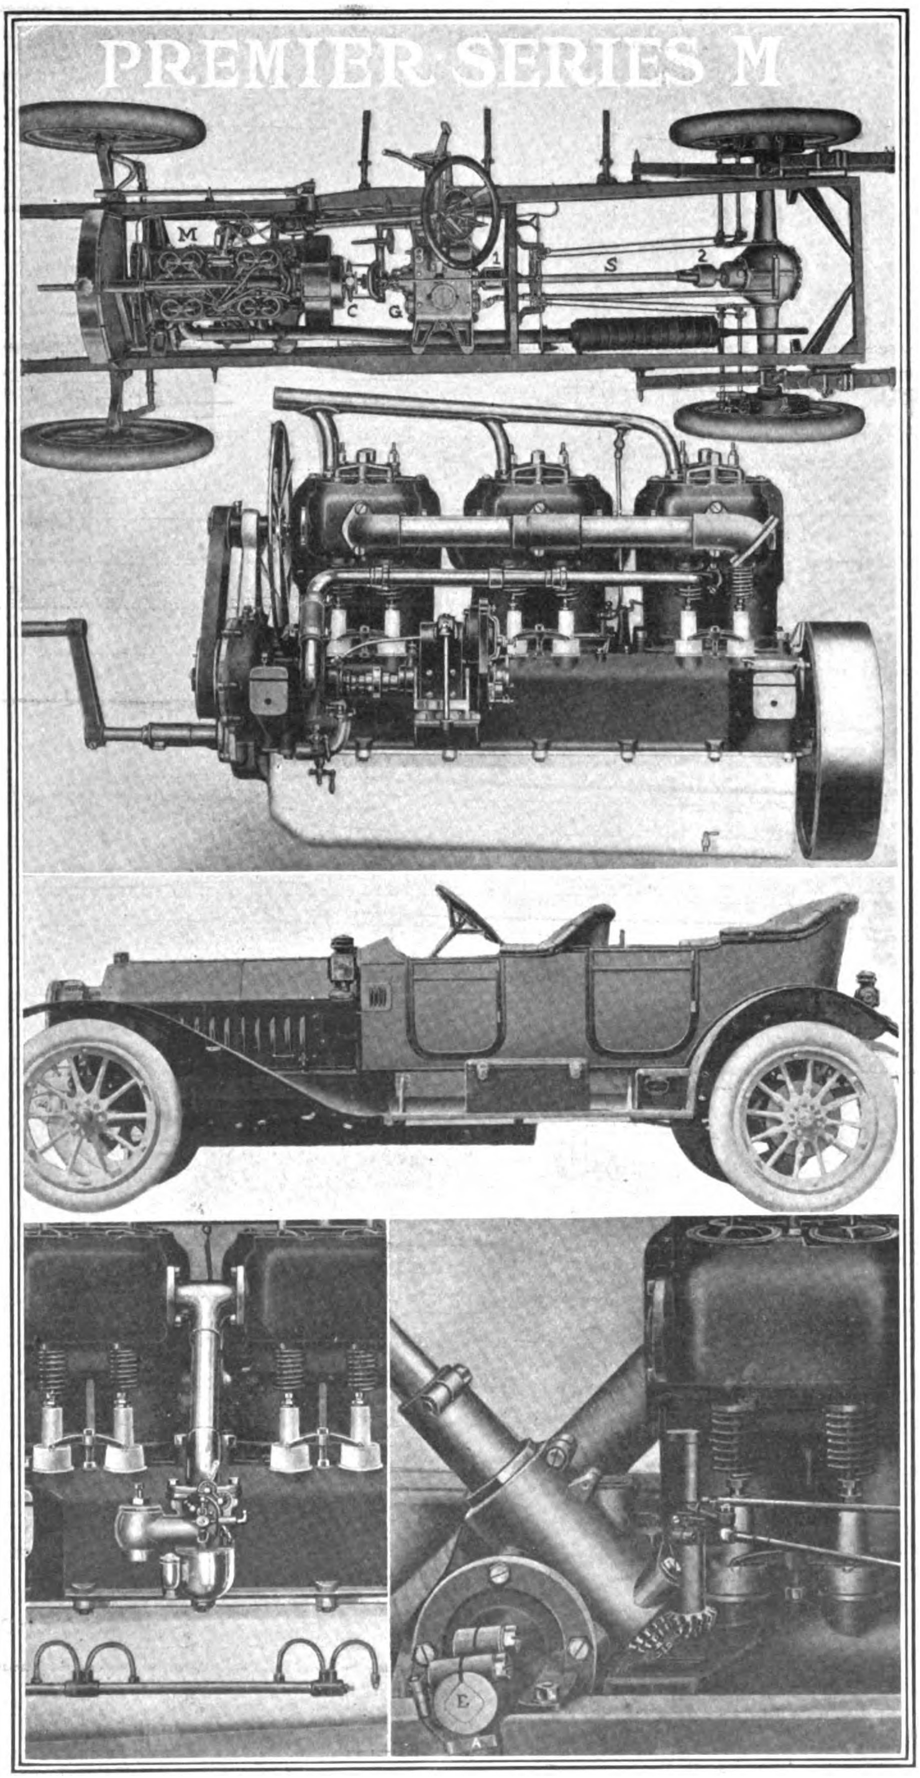


Fig. 1—Group of Premier Car Parts

In the upper illustration is seen the 1912 Premier four-cylinder chassis, showing the new style of brake equalizers. Beneath it appears the magneto side of the six-cylinder motor. The 1912 body styles is next shown. At the bottom on the left is the simple type of intake manifold on the four-cylinder motor and at the right is the steering gear mounted above the frame line so that the shaft E is carried over the frame side member instead of through it as is very frequent practice

THE policy of the Premier Motor Manufacturing Company for 1911 will be continued for the year 1912. The company will build both four and six-cylinder chassis, the ratio of production being approximately four times as many six-cylinder as four-cylinder cars. The constructions of 1911 are continued except in minor details where changes have been made by the engineering department. In the motor the improvements are largely confined to the use of improved push rods and push-rod guides, for lifting the valve stems. The push rods are now made with rollers on their lower ends to bear upon the cams and the camshaft. These rollers will eliminate side thrust to a large extent. An improvement has been made in the oiling system by adding a lead from the sight feed on the dash to the bearing of the magneto shaft and thence to the timing gear housing at the forward end of the motor. Helical timing gears introduced in the early part of the 1911 season are continued.

The group of illustrations, marked Fig. 1, give a general conception of the Premier chassis, the four-cylinder type being here illustrated. The chassis is a three-unit type, the motor M constituting the first unit, and carrying in the flywheel the multiple-disc clutch C. The selective gearset G is the second unit. The rear axle comprises the third unit. Between the gearbox and real axle is a propeller shaft S with two universal joints, 1 and 2. Between the motor and gearbox is a telescoping joint to allow for clutch disengagement. The motors whether of the four or six-cylinder type used the same twin cylinder castings of T-design, the bore being 4 1-2 inches, and the stroke 5 1-4. This is a stroke-bore ratio of 1.16 to 1. The motors are symmetrical units, having the carbureter placed centrally on the right side. and the water pump and magneto carried forward on the left side, a design which leaves all of the intake and exhaust valve springs accessible for removal if such becomes necessary.

Every care is taken in the manufacture of the motor, and one point which stands out in this respect is that the upper portion of the crankcase, instead of being an aluminum casting, is a close-grained semi-steel casting, which material is well adapted to hold the threads for the crankshaft bearings as well as the lower half of the case. The lower portion of the case, which serves the purpose of an oil retainer, is an aluminum casting. In the manufacture of the cylinder castings the cylinders are, after being cast, pickled to remove core sand. This done they are given a rough machining process and then heat-treated to relieve the tension of the outside scale. This process completed, they are bored, enameled and finally ground. The pistons, of gray iron, are each fitted with three compression rings. Connecting rods are I-section drop forgings and have large bearings. The crankshaft of the six cylinder Premier is illustrated in the group on Fig. 2. It has four main bearings, whereas on the four-cylinder motor but three bearings are used.

The oiling system of the Premier is a circulating one, the complete details of which are shown in Fig. 2. In the top illustration is shown the oil pump P outside of the oil reservoir. It delivers the oil through a horizontal pipe to the six leads or branches 1, 2, 3, 4, 5 and 6. Each lead pours its supply into a trough T in the base of the crankcase, which is shown in the bottom illustration. On the bottom on each connecting rod is an oil scoop S which dips into the cil trough, picking up the oil, carrying a part of it to the lower connecting rod bearing and splashing a portion into the open cylinder. The oil which overflows from the troughs T drains into the reservoir to the pump, whence it is ready for recirculation. The size of the oil scoops S on the connecting rod caps has been experimentally calculated so that it is claimed they supply just sufficient lubrication without any tendency to induce smoking. Over each crankshaft bearing is a pocket which is filled by the splash, the oil leading from the pocket into the bearings. The oil reservoir, formed by the base of the crankcase, has capacity for two to three gallons at one filling, which is sufficient for 500 to 750 miles of road travel. To insure the driver as to the certainty of motor lubrication a sight feed has been placed on the dash. In addition to the motor lubrication there are various parts of the car, chassis, oil and grease cups, which take care of the gearset, rear axle, universal joints and other necessities.

Ignition on both four and six-cylinder Premier models is the conventional dual type, current being supplied by high-tension magneto. The simplicity of former years in the use of a simplified intake manifold is continued, the Premier Company being the first concern in America to use the simple vertical pipe from the carbureter to a point between the valve housings of the front and rear cylinder pair, as illustrated at the lower left corner of Fig. 1. This manifold calls for but a T-union between the cylinder castings, the remainder of the air passage to each casting being a water-jacketed space within the casting. The manifold employed on the six-cylinder motor, a Y-type, is shown in the upper illustration, Fig. 2. The use of manifolds of this nature adds to the accessibility of valve parts.

The clutch is of the multiple-disc type encased and running in oil. It is made of twenty-one plates arranged in alternate sets, ten in one and eleven in the other. Fig. 3 shows the general makeup and also illustrates one of the plates P with its cork inserts. These inserts are used to prevent gripping and allow of picking up car speed and drawing down to that of the motor without strain or shock on the mechanism of the car. The shaft between the clutch

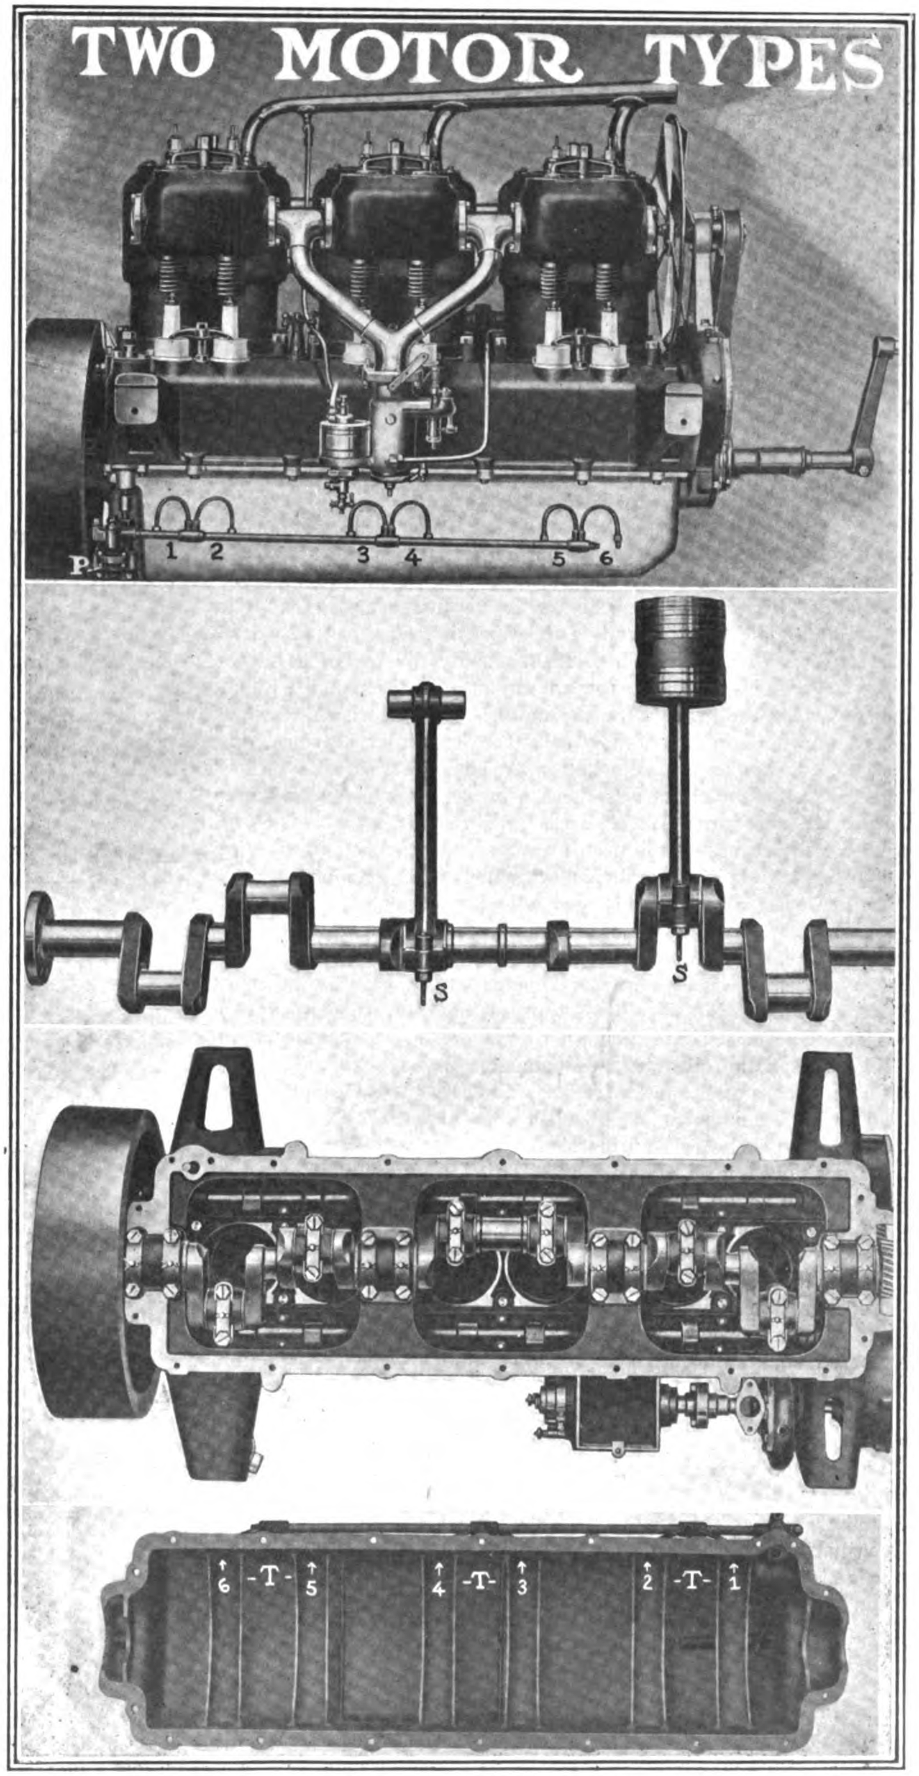

Fig. 2—Group of Premier Car Parts

This illustration shows at the top the intake side of the simple intake manifold used on this motor, a part of the gas passages are cored into the valve chambers in the castings. The second illustrations show the scoops on the caps of the connecting rods for oiling the bearings. The bottom illustration is of the inside of the crankcase base showing the six oil troughs into which the scoops S dip, the oil being fed into these troughs by means of the six oil leads marked 1, 2, 3, 4, 5 and 6

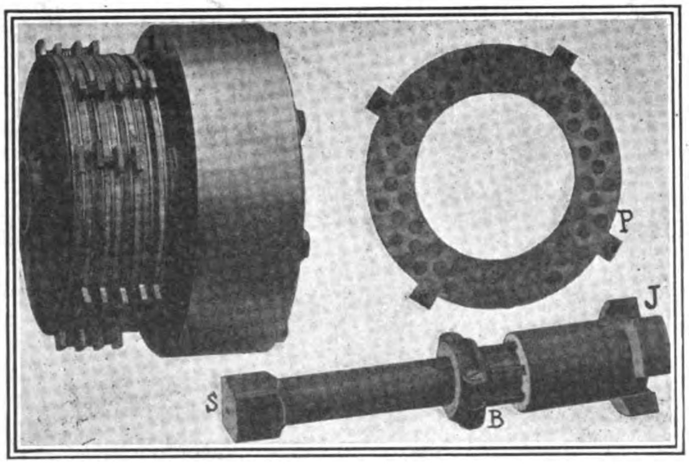

Fig. 3.—Premier multiple-disc clutch for 1912

and the greatest telescopes the part J with three jaw teeth extending into the gearbox and forming part of the direct drive clutch. This sliding member works on a shaft B with four broaches. The forward end of the shaft is squared at S, where it connects with the clutch mechanism. By the use of a releasing collar it is possible to remove any part of the clutch without dismounting the gearbox or the motor. The clutch release has been improved in that it now carries two annular bearings, one at the top and one at the bottom. The release consists of a bronze collar which carries these bearings, which work against hardened and ground steel discs. The release is claimed to be quite free because of the use of annular bearings and the bronze clutch plates being completely separated from one another by the use of steel springs between adjacent plates.

Nine years ago the Premier company on its original cars made use of a sliding gearset, a type now universally in the car field and one which has been improved upon year by year by the company. It is of the selective design, giving three forward variations. The design and location of the gearbox is illustrated in Fig. 4. It is an oil-tight aluminum case carried direct from the side members of the main frame. To carry the main and countershafts five imported ball bearings are used. The gears are cut from nickel steel forgings. At each end of the main shaft are positioned little plates on the shaft, so placed that by their centrifugal action they throw back upon the gears any lubricant tending to work out past the end of the shaft. This is an ingenious scheme to prevent the leaking of lubricant from the case.

Back of the gearset and connecting it with the rear axle is the propeller shaft with its two universals packed in grease. Each end of the propeller shaft is a tapered square which fits into a tapered square hole in the universal joint. This construction gives a positive connection with the proper amount of tightness. Parallelling the propeller shaft is a V-design of torsion tube, the spreading arms spanning the differential housing at the rear. The front end of the rod is retained in a spring cushion ball joint.

The Premier rear axle has always been a special feature in conjunction with these cars and is illustrated in Fig. 6. Each axle sleeve A is a tapered and slightly bell-shaped turned forging, and the differential housing G is a crucible steel casting. The axle housing is not supported by any truss rods, but has an internally ribbed housing which gives added strength. The axle drive-shafts B are carried at the inner ends on roller bearings and the outer end on a single annular ball bearing. On the axle drive-shaft is an integral clutch member C which locks with a corresponding clutch member D formed integrally with the brake drum. The construction of the clutch part D may be seen to advantage in Fig. 5.

The differential is of the bevel gear type and upon it is mounted the main driving gear, and through hand-holes in the rear of the housing the differential and the gear may be adjusted laterally to take up any wear. Correspondingly, the pinion which transmits the rotary motion of the driving shaft to the floating axle gear is adjustable longitudinally, so that with these two adjustments the gears can readily be made to mesh properly should it be necessary to change their setting. There are eight antifriction bearings in the axle, the roller thrust bearing on each side of the differential, imported annular bearings at each outer end of the axle shaft and four bearings in connection with the pinion, two of which are thrust bearings. The pinion is forged solid with the shaft, contrary to the usual practice of keying it. This construction obviates any danger of a loosened gear and gives a stronger one. The pinion is mounted between two imported annular bearings, an important feature and one much more desired than the common method of having both bearings on the front end, leaving the rear unsupported. The thrust is taken by two annular bearings with an adjusting collar to provide adjustment.

At the ends of the axle housing are the brake supports, rigidly attached and hot riveted so that they cannot loosen. The brake drums are integral parts of the wheel hubs not separable and bolted on. The live axle shafts are squared at the inner ends to fit into the differential. A liberal annular bearing is placed almost in the direct load-carrying center of each rear wheel, a construction made possible by the use of the semi-floating live axle. With this type of axle also the distance between bearings is about 24 inches, giving a large distance through which the supporting action against lateral strains takes place.

Some changes have been made in conjunction with the brakes in that the internal expanding sets are now steel bands covered with raybestos. Formerly bronze shoes with cork inserts were used. The external contracting brakes are steel bands lined with raybestos. A change has been made in the equalizing principle of these brakes in that short equalizers are used. (See Fig. 1, top illustration.) These equalizers are placed immediately in rear of the frame cross-member back of the gearset. For this year the equalizers were long members working in slots through the side members of the frame. With the new construction all of the brake operating pars are located within the side members of the frame. The two shafts for operating the brakes on each wheel are carried on the rear axle housing and in front of it. Adjustment of the brakes can be made by lifting the floor boards in front of the driver's seat. The brakes have a total area of 526 square inches.

In the Premier running gear the frame side members are heavily reinforced midway of the axles and the channel lips gradually taper to the rear. The rear corners are braced by pressed steel gusset plates and at the front are integral gusset plates which extend down to the radiator supports. The front springs are 36 inches long and the three-quarter elliptic rear ones have the bottom section 50 inches and the top section 26.

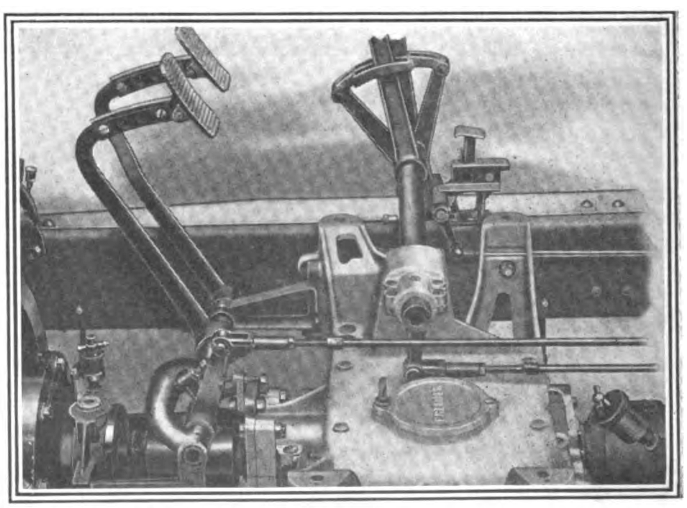

Fig. 4—Gearbox and operating pedals on Premier

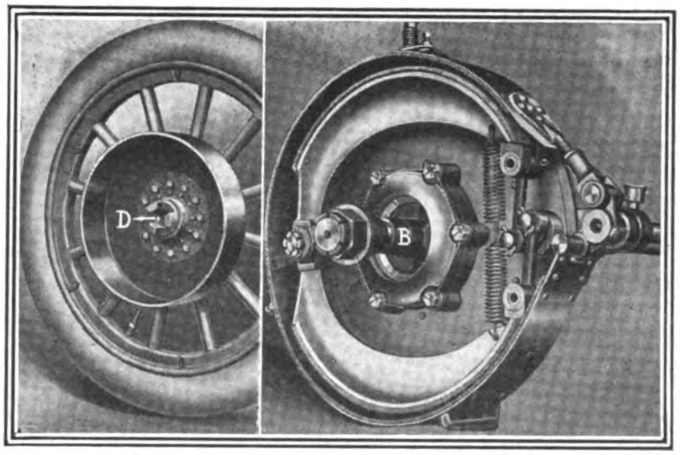

Fig. 5—Improved brakes on the 1912 Premier models

The front axle is a one-piece forging with Elliott-type ends. In the knuckle design the load-carrying center has been brought into the closest relation to a center line through a king bolt constituting the steering center. Thrust bearings are used in the top of the king bolt to carry the vertical load. The lower end of the bolt is held in hardened and ground bushings, the steering cross rod being placed in the rear of the axle. The front wheels are carried on tapered roller bearings.

The general location of the Premier steering gear is shown in the lower right-hand corner of Fig. 1. The bottom of the steering column carries a steel worm in mesh with a spiral gear which is carried on the shaft E. The shaft has a squared end and onto it is mounted the radius arm A, which extends downward and has a ball joint on its lower end. The shaft E is mounted in eccentric bronze bushings so that it can be adjusted with relation to the worm on the steering column. The gear on the shaft E travels less than one-quarter of its circumference for any movement of the steering wheel, and should this quarter become worn it can be shifted so that any of the three remaining quarters can be meshed with the worm, thereby increasing the wearing field of the gear fourfold.

One feature of the Premier body line is that the five and seven-passenger bodies are interchangeable on the four and six-cylinder chassis. In addition to regular touring body styles the 1912 line includes close-coupled types for four and five passengers, the Clubman design, and roadster styles. Inclosed types of limousine lines are included. In all the standard finish is blue black with black panel lines and light striping. The wheelbase on the four-cylinder model is 126 inches and that on the six-cylinder is 140 inches. Both chassis are fitted with Firestone demountable rims. Tire sizes on the four-cylinder cars are 36 by 4 1-2 all around, and on the six-cylinder chassis the front wheels carry 36 by 4 1-2-inch sizes and the rear wheels 37 by 5. This arrangement on the six-cylinder chassis gives a larger wheel tire, but it is a size which is interchangeable with the front wheels so that there is no necessity to carry a double supply of spare tires.

Modern Rustproofing Methods

By the Bontempi rustproofing process, one of the latest along this line, the iron or steel article to be treated is placed in a muffle furnace and brought to a heat of about 1350° Fahrenheit, when dry superheated steam is introduced in the furnace and a cartridge containing certain chemicals is broken, also inside of the furnace, and the steam in combination with the chemicals forms certain gases which penetrate into the heated steel and impart to it a rustproof shell which is of greyish color and whose thickness depends upon the time of exposure. If it is desired to conserve the properties of the iron or steel article as much as possible, it is kept under cover, so as to protect it against oxidation from the atmosphere and cooled very slowly. As this process practically involves annealing of the metal and, in the case of wire chains for example, has been known to reduce the tensile strength of the part considerably, it is scarcely applicable to automobile parts which have been heat-treated or hardened, and it is in fact quite possible, in the absence of tests in proof or disproof, that the process may weaken any part or article to which it is applied. On the other hand, the applications of the process are very numerous in other directions where the question of strength is subordinate to questions of surface and appearance. The advantages over sherardizing consist mainly in the coloring of the coat, which may be made black and matt black, as well as grey, by the use of oil on the heated surface, and in the fact that the active gases take effect in every nook and corner and particularly on the inside of hollow objects, while the tumbling process required for sherardizing cannot readily be used for any but smooth exterior surfaces and also requires considerably longer time. The company which is now erecting furnaces at Bridgeport, Conn., contemplates to experiment considerably before undertaking to recommend its process for articles employed for dynamic work, having a wide field where the rustproofing as such is the principal requirement. It is stated that articles treated by the Bontempi process resist attacks from acids and preserve their appearance indefinitely.

As one of the new methods by which other substances than carbon are introduced into iron and steel by cementation, and foreshadowing the time when all automobile parts may be machined in common soft steel and afterwards transformed into parts of great hardness and strength through the introduction of suitable alloys, whether these alloys penetrate the steel in solid or in gaseous form, the rustproofing and sherardizing processes claim the attention of automobile engineers.

Honesty Best in the End

The feeling of distrust with which the average car owner looks upon the public garage has been discussed from various angles, and many owners naturally dread the idea of entrusting their cars and pocketbooks in the hands of those whose honesty has been so much debated. Nothing is so hard to regain as a lost reputation, and the short-sightedness of the few in the earlier days of the public garage business is much to blame for the existing conditions.

Restrictive legislation and the vigilance of the owners and garage proprietors, who have lost the idea that catering to a dishonest chauffeur is good business policy, have gone far in limiting the activities of the joy rider, so that on the whole the prospects are not so dark as they are painted. In the matter of repairs, the same may be truthfully said to be the case, although in this as in all other matters of purchase the energetic salesman will often have to be restrained.

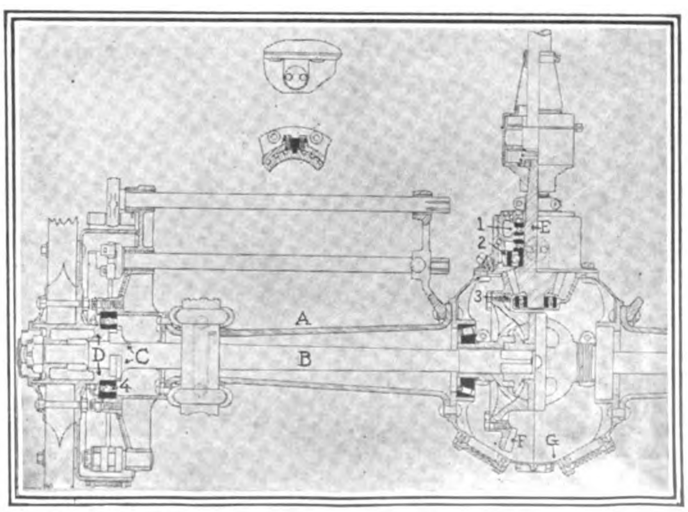

Fig. 6—The patented rear axle on the Premier

How to Analyze the

IN order to get the maximum of work out of a motor, leaving all other things out of consideration, it is absolutely necessary that the mixture is right; that is, that gasoline and air are contained therein in a definite ratio, which, when the mixture is completely burned, will result in the motor's delivering the highest possible amount of power which may be realized from the quantity of fuel used.

The ideal mixture, according to numerous tests, contains about 14 volumes of air to one of gasoline. Gasoline, as is well known, is essentially a mixture of various hydrocarbons, prevalent among which is hexane, C_6H_{14}. This compound contains a fixed amount of energy per pound, which is set free and may be utilized if all of the carbon (C) and of the hydrogen (H) composing the hexane are burned to carbon dioxide and water, respectively. If the ratio 1 to 14 is diminished the gasoline will not be offered enough oxygen, and consequently part of it will escape unburnt or partly burnt, forming hydrogen and carbon monoxide. If, however, a mixture of a ratio higher than 1 to 14 is employed the surplus of oxygen will be of no use, and the additional amount of nitrogen which always accompanies oxygen in the air will go to stifle combustion and to decrease the rate of flame propagation.

Thus, a rich mixture will result in an excess of carbon monoxide in the exhaust of a motor, whereas too lean a mixture will produce an exhaust containing a high percentage of oxygen. In both cases the thermal efficiency is below the maximum. The maximum thermal efficiency is said to obtain at the ratio of 1 to 14.5. Some empirical results, compiled by a foreign expert, are given in the following table:

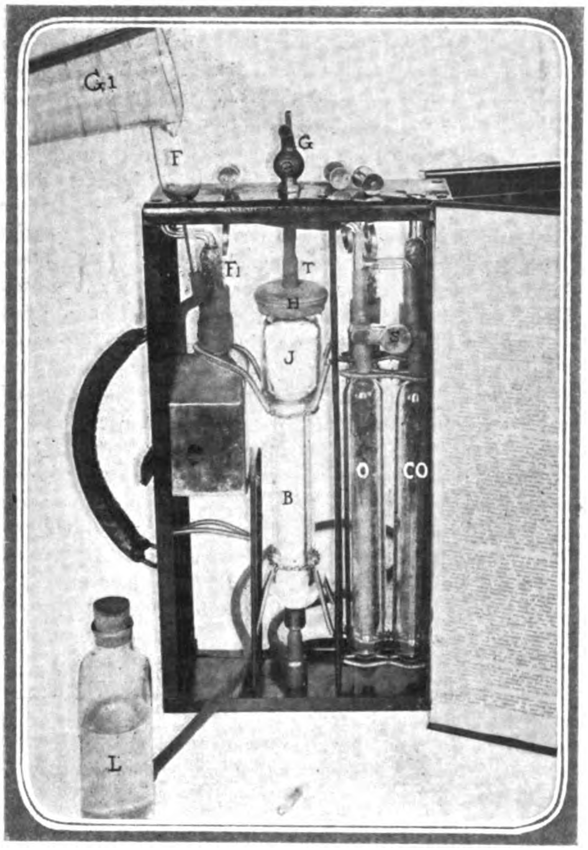

Fig. 1—Getting ready for the carbon dioxide analysis. The caustic is cautiously poured into the CO_2 chamber through a funnel, and the problem is not to spill any of the highly active alkali on either one's hands or clothes

RELATIONS BETWEEN THERMAL EFFICIENCY AND EXHAUST COMPOSITION

Thermal Efficiency.	Per Cent. CO_2.	Per Cent. H.	Per Cent. CO.
.162	6.0	8.7	11.6
.204	9.6	2.65	6.25
.238	10.6	2.1	5.0
.244	10.9	Not determined	
.252	12.8	Not determined	
.261	13.5	Not determined	

These primary considerations will serve to carry conviction to the effect that the efficiency of combustion will react infallibly upon the composition of motor exhaust. Therefore this composition permits of drawing safe conclusions as to whether anything, and what, is at fault about the process of combustion taking place in the engine cylinders; it will also be a positive indication as to what means have to be resorted to in order to remedy the existing trouble; whether the motor needs a richer or leaner mixture, and whether the ignition is to be advanced or retarded.

The analysis of the exhaust is by far easier than it is generally considered to be; in fact, the necessary apparatus has to-day reached a state of development where no chemical knowledge whatever is required to do this work. There are several methods of making an analysis of a gaseous mixture, and the simplest one, which is sufficiently accurate for any tests the automobile user or engineer might be interested in, will be described in the following.

For analysis a sample of the gas to be tested is stored in a bent glass tube between two liquid levels and the space taken up by the gas is noted. After this has been done all of the gas sample is forced through a solution of caustic potash, which instantly absorbs the entire carbon dioxide content of the gas. Hereafter the gas volume is again measured and its volume noted. In order to determine the respective amounts of oxygn and carbon monoxide, the gas sample is first sent through a solution of pyrogallic acid, where the oxygen is absorbed, after which the rest of the sample is measured and then forced through a cuprous ammonia solution, where the carbon monoxide is held back. The rest of the gas which remains after this treatment is practically pure nitrogen.

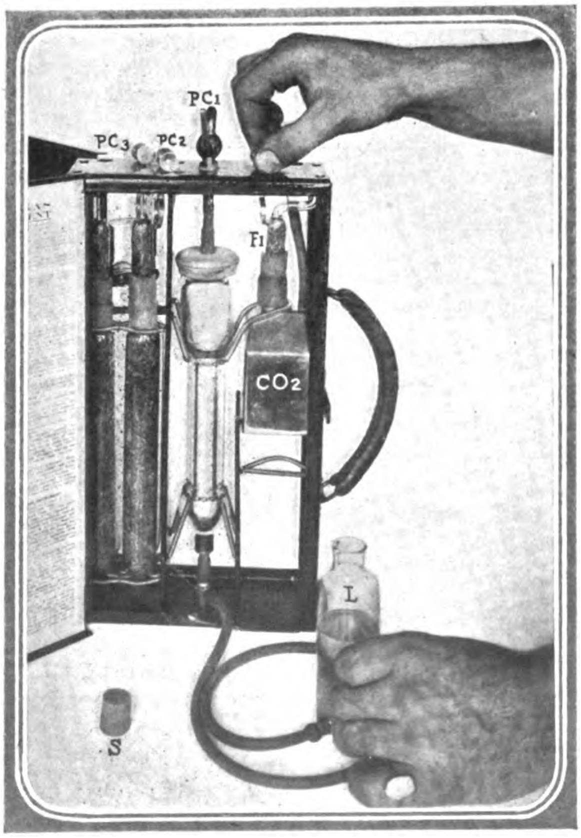

Fig. 2—Regulating the level of the caustic potash. With the cock closed tightly and pinch check held wide open, the leveling bottle is manipulated so as to raise the caustic to the top of the metal filing above the CO_2 chamber

The apparatus used in the analysis is the Hays Special Gas Analysis Instrument shown in Fig. 1. The apparatus is carried in a metal case (Fig. 5) finished in black and provided with a handle. The burette B,

Exhaust of the Motor

which is surrounded by a water-jacket J, carries a scale and is connected, at its upper end, to a cock G, while a connection is provided at the bottom to permit of establishing a communication between the burette and the leveling bottle L, which normally is placed below the chamber marked CO_2 in the illustration. The CO_2 chamber has two upper outlets, one corresponding by means of a rubber tube to the cock G, while to the other outlet is fitted a short piece of rubber hose, into which fits a glass funnel F. In the connection between CO_2 chamber and cock G is interposed a glass tube filled with metal filings which retain all solid matter contained in a liquid passing through the tube. The cock G has also two other connections, which lead to two vertical glass chambers marked O and CO, which serve for the absorption of oxygen and carbon monoxide, respectively. Each of these chambers corresponds with a glass tube of the same volume on the opposite side of the instrument, and it is on that side that the connections from cock G lead to the tubes. On the side shown in Fig. 1, however, the O and CO chambers are connected through a T-glass tube and some rubber tubing, which is normally squeezed close by the screw clamp S.

The chemicals used for the analysis are seen in Fig. 3. Caustic potash is supplied with the instrument, this material being the most efficacious for the absorption of carbon dioxide. The potash is seen at S and S_1, and it is important that in reordering the potash none should be bought which has been purified by means of alcohol. Pyrogallic acid, commonly called pyro, P and Pl, comes in small tubes, as does cuprous chloride, which is shown at C and C_1. Hydrochloric (muriatic) acid, H, is used in the analysis, because it does not react with carbon dioxide, monoxide or oxygen. At A is shown a bottle with ammonia solution, containing .90 per cent. of ammonia. Like the ammonium chloride, A_1, it is used in the determination of carbon monoxide. The bottle B as well as glass funnel F also play their parts in the process. The aspirator A2 is interposed in the rubber-tube line, about 6 feet from the end of the tube which is attached to the cock G.

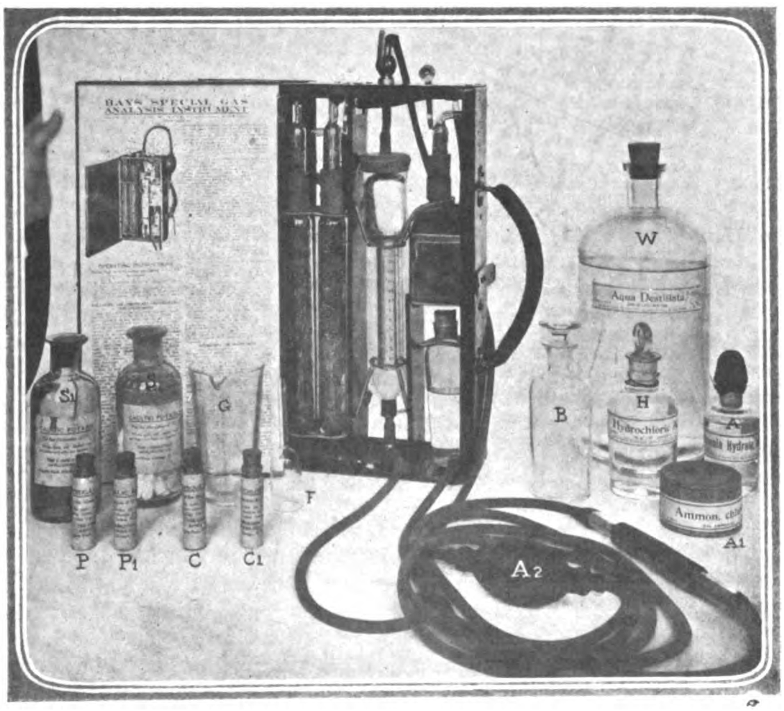

Fig. 3—Line-up of apparatus and chemicals for analysis. Preparations might look tremendous, but the operations are simpler than they seem. Besides muriatic acid and aqua distillata, only caustic potash comes into play when carbon dioxide is to be determined

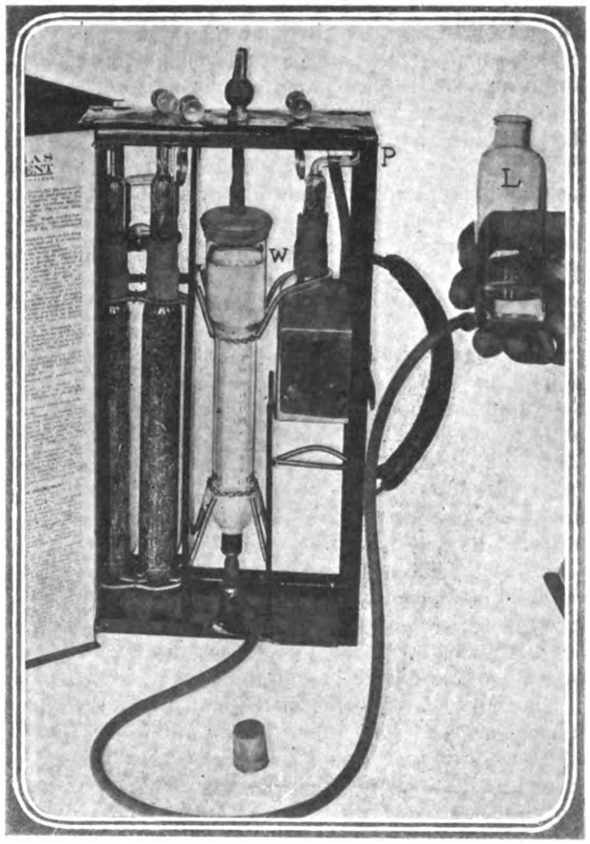

Fig. 4—Filling the burette with acid water. For this purpose the cock is turned open and the leveling bottle raised as shown in the picture. This operation is also used when it is necessary to coax the caustic into the chamber

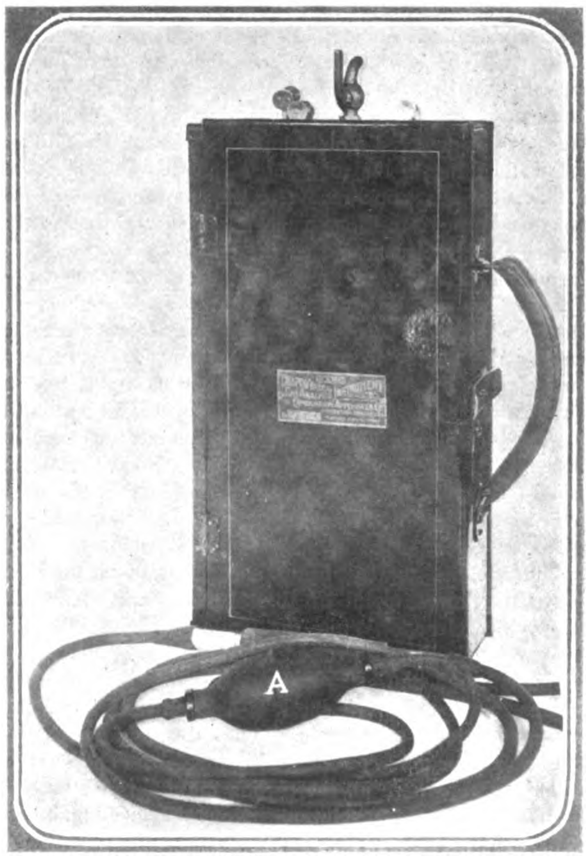

Fig. 5—View of the instrument when not in use. It is of first importance to remember that the cock should then be closed, and the plug be used to seal up the rubber tube above CO_2 chamber, lest disastrous results are the expectation

Before beginning the actual analysis, the rubber hood H of the jacket J in Fig. 1 is lifted and the jacket filled with water up to the capillary tube T. Then the leveling bottle is filled to about two-thirds with distilled water, after which half a teaspoonful of hydrochlorid acid is added. The leveling bottle should always be closed with the rubber stop furnished therewith, when not in use. The bottle being filled with dilute acid, one of the bottles containing the sticks of caustic potash is filled with distilled water, closed and shaken until the caustic has been dissolved. Then the handle of the cock is brought to a vertically upright position, and the funnel is put in place as in Fig. 1. Hereafter pinch check PC_1—the one next to the CO_2 chamber—is pressed by two fingers, and the caustic having been filled into the measuring glass up to the 3 1-2-ounce mark, is poured into the CO_2 chamber. In case the potash should stay in the funnel and refuse to flow down into the chamber, it will be necessary to use the leveling bottle to attain the end sought. This is done as follows: First release the pressure on the pinch check. Then, after removing the leveling bottle from its compartment, the stop is taken out and the bottle raised. The hydrochloric-acid solution will flow from the leveling bottle into the burette and fill it. When the liquid reaches the height of the capillary tube, Fig. 4, the leveling bottle is held in place and the cock handle turned to a horizontal position. Now the bottle is lowered while the pinch check PC_1 (Fig. 3) is held open with the thumb and forefinger, until all of the caustic has flown into the CO_2 chamber. Then PC_1 is released. Now the instrument is ready for making one or more analyses for carbon dioxide.

The apparatus is placed in a stable position, preferably by hanging it on a nail through the hole in the metal casing. The funnel—or the plug which is put in the rubber tube above the CO_2 chamber when the instrument is not in use—is taken out of the tube, and the stopper removed from the leveling bottle. While the handle of the cock is still in the horizontal position, the leveling bottle is raised about 2 inches so as to drive any potash which may be in the connection between burette and CO_2 chamber back into the latter. The pinch check PC_1 must be held open while this is done. Now the cock handle is turned up vertically and the leveling bottle raised till the level in the burette rises up to the capillary tube. Then the handle of the cock is turned to a horizontal position, and, while PC_1 is still held open, the bottle is lowered slowly until the caustic rises to the top of the metal filing in the tube above the CO_2 chamber.

The apparatus is now ready for the gas sample to be introduced. For his purpose the long rubber tube carrying the aspirator is slipped over the open end of the cock, while a piece of 1-8-inch gaspipe is slipped into the other end of the rubber-tubing line. The gaspipe is inserted into the outlet of the muffler, and the aspirator worked. If this is done after the cock has been opened by turning the handle to a vertical position, the exhaust will pass through the burette and bubble up through the leveling bottle. This should be continued until the operator feels sure all the air has been displaced from the burette, when the cock should be closed by turning the handle to a horizontal position. Then bring the level of the liquid in the leveling bottle to the exact level of the zero mark on the burette. If the handle is turned up to an elevation of 45 degrees the liquid will rise slowly in the burette, its surface being curved downward at the center. When the lowest point of this surface reaches the zero mark the cock is closed. While the liquid flows into the burette the leveling bottle must be raised a little, so as to keep the levels in the burette and bottle the same at all times.

Then, while the pinch check is held open with the fingers, the leveling bottle is raised slowly until the liquid rises in the burette up to the capillary tube. This forces the gas sample into the CO_2 chamber, where all the carbon dioxide is instantly dissolved in the caustic potash solution. Now the leveling bottle is lowered quickly until the level falls in the burette down to the 15 mark. After this lower the bottle slowly until the caustic rises again to the top of the filling in the tube above the CO_2 chamber. When the potash has reached this height release the pinch check and bring the leveling bottle to such a height that the levels of the liquid in bottle and burette fall into the same plane. The number found on the burette at the lowest point of the surface is the percentage of carbon dioxide in the gas sample tested.

Hereafter the rest of the sample may be tested for oxygen and carbon monoxide. For this purpose the respective chambers are filled with the proper reagents in the manner given in the instruction accompanying the instrument when it comes from the maker. These tests, however, take more time than the one for carbon dioxide, and the average automobilist is more liable to make a mistake while undertaking them. Incidentally, they are of less interest than the carbon dioxide determination, because what the engineer and autoist desires is a complete and efficient combustion, or, what means the same, a maximum of carbon dioxide in the exhaust. Therefore, it will be much simpler to work only with carbon dioxide analyses, adjusting the carbureter in one way or another, until the highest carbon dioxide percentage is obtained. This percentage is between 12 and 14 per cent., and on the average a motorist may be quite satisfied to run on a mixture that burns to an exhaust containing about 12 or 13 per cent. of carbon dioxide, because the degree of combustion prevalent in average automobile practice is hardly three-fourths of the one producing an exhaust with 14 per cent. carbon dioxide. At the same time it may be said that when the carbon dioxide content of the exhaust has risen to 13 or 14 per cent. the carbon monoxide therein is a very negligible quantity.

A few remarks respecting incorrect mixtures may not be out of place here. It is well known that gasoline is not explosive, and combustible only if mixed with no less than a minimum of air. This explains the possibility of burning gasoline in a lamp in the same manner as crude oil, and no spontaneous combustion will be experienced unless some of the fuel is permitted to evaporate and mix with the surrounding air. A spark occurring in a body of liquid gasoline contained in a tank will not be efficacious in igniting it, but will result in the most rapid combustion of the fuel if it is in the gaseous state and mixed with oxygen.

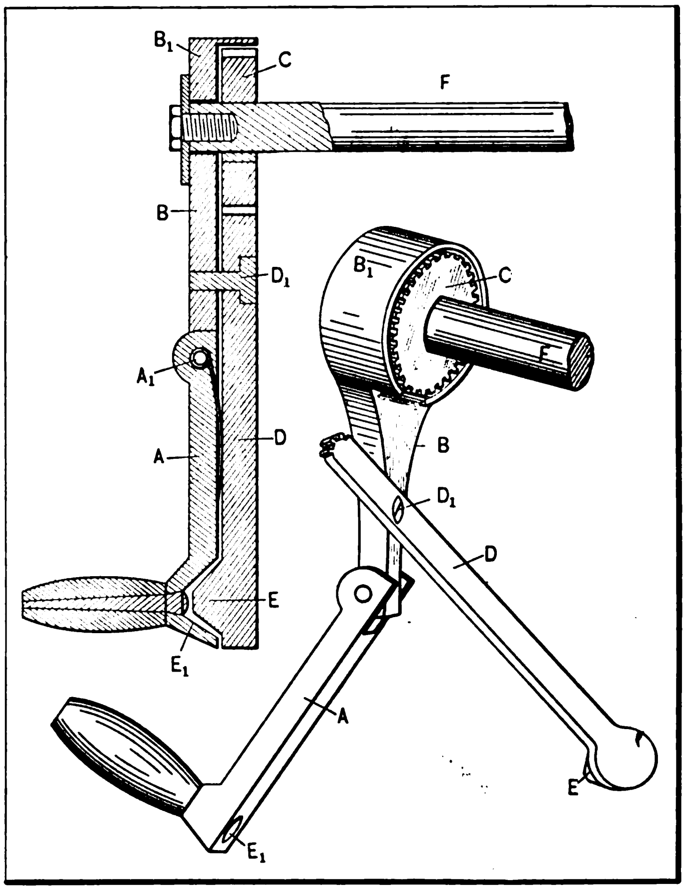
On the other hand too lean a mixture will not burn. Below a certain gasoline content the gasoline-air mixture is incombustible. This is well illustrated by the fact that not infrequently gasoline is spilled in the street and allowed to mix with air; at the same time, there are enough opportunities of igniting this mixture, so that according to the law of probabilities gasoline fires in the street should not be of such rare occurrence as they are in practice. The reason therefore is that the gasoline is rapidly distributed through the air currents always obtaining in a street, so that even a match lighted at a distance of say 10 feet away from the gasoline spilled will hardly ever ignite the same. Whereas in a closed room, such as a garage, the same experiment would undoubtedly result in a serious fire. A similar case can be observed in any city apartment every day. In a well-ventilated room, the gas of a lamp may have been turned on for minutes and plenty of gas might have left the burner; yet, if a match is applied to the burner, only the gas next to it will ignite, and the farther-away portions, which are mixed with a vast surplus of air, will not avail themselves of their opportunity to burn. In this instance, too, unless the room is well ventilated and the gas thoroughly diluted by plenty of air, a highly combustible mixture will be formed and ignited at the earliest occasion.

The apparatus before described is handy enough, and after having become accustomed to work with it by a dozen tests or so, the automobilist who is out for economy will find it a very convenient instrument. The construction is compact, and as long as the cock is kept closed and the glass plug in the rubber tube above the CO_2 chamber when the instrument is not in use, there is no danger of spilling any of the chemicals over the car as long as the glass parts of the apparatus remain unbroken, so that one may keep the analyzer in almost any place at all. It is manufactured by the Combustion Appliances Company, Rogers Park, Chicago, Ill.

British Starting Crank

A CRANK which has been brought out in the English accessory market is described and illustrated with the assurance added that the crank has proved perfectly reliable in practice and is obtainable at a very reasonable price, besides that it may be fitted to any motor crankshaft by varying the bore of the motor shaft extension on which the crank is mounted. The description as given seems to be at variance with the possibilities of mechanics and is rendered in the following with modifications which, it is believed, represent the true construction of the crank. F is the motor shaft extension whose bore is fitted over the motor shaft end, not shown, and secured by set screws. This extension is cylindrical, and to it is keyed the pinion C. The crank arm B is journaled upon the end portion of the extension shaft with its hub adjacent to pinion C and fitting over it as a casing by means of a circular flange except where the crank arm joins the hub. A screw bolt holds a washer against the extension shaft end, thereby securing the crank hub B1 while leaving it free to turn around. The free end of B is hinged to the piece A which forms the outer end of the crank arm with the usual handgrip, and the spindle which carries the grip is formed on the opposite side with a conical recess E1. D is another portion of the complete crank arm and is pivoted in B at D1. Its short end is provided with teeth which engage pinion C and its outer end is formed with a conical projection fitting into the conical recess E1 in the end of A. A spring at the hinge joint A1 holds A away from D and E1 disengaged from E unless the hand of the operator starting the car exerts an opposite pressure upon the grip.

When it is desired to start the motor, this pressure is brought to bear, and the crank is turned in the same manner starting cranks are ordinarily turned. In case of back fire, however, if the pinion C is rotated in the reverse direction, the shock of its teeth against the teeth on the short end of D releases the engagement at E and E1 and throws D around the pivot pin at D1, thereby leaving the pinion and the motor shaft extension free to rotate, while the crank is released. Apparently the rapidity of motion caused by the pinion acting on a very short lever has much to do with throwing the conical joint at E out of action, while the angle of the cone in conjunction with the spring at A1 contributes to throwing A forward. The device can of course be mounted on the motor shaft with the customary clutch and release spring in addition to the features described, so that the successful starting of the motor will not throw the parts out of their normal assembled relations every time the crank is used.—From *The Motor,* Sept. 23.



Safety starting crank recently introduced in England

Harking Back a Decade

JUST ten years ago the *Motor Review,* the forerunner of THE AUTOMOBILE, published the following:

Alexander Winton created a new world's record for the mile on an oval track last week when he negotiated the Grosse Point track in 1:06 2-5. The best previous was Fournier's 1:06 4-5, made on Empire City track, New York. This record was made in the third mile of a 10-mile trial and was equaled in the seventh mile.

The list of exhibitors at the second annual display of motor vehicles, which will open in Madison Square Garden on November 2 under the auspices of the Automobile Club of America, includes the names of forty-one makers of automobiles and forty-two of accessories. Against the protests of the National Association of Automobile Manufacturers, the promoters decided to allow French cars to be exhibited.

Rochester, N. Y., is experimenting with the automobile for collecting mail, and its work as compared with that of the horse-drawn vehicles then in use showed a time saving of 61 per cent.

The Automobile Club of America pledged its support in the work of enforcing the new speed ordinances of Long Island. Secretary S. M. Butler, of the A. C. A., is especially prominent in the matter.

The necessity for the formation of a national association in the interest of the users of motor vehicles is editorially dilated upon and attention is called to the fact that the Automobile Club of America has appointed a committee to consider the matter.

The Automobile Club of New Jersey is arranging to hold a hill-climbing contest on the famous Eagle Rock Hill on election day.

Boston announces its first automobile show. It is to be held in the new Automobile Building during the ten days from November 15 to 25. Admission will be free and after the regular show a permanent exhibition will be conducted.

New York motorists are congratulating themselves on the early completion of a specially built speedway for automobiles. It follows the windings of the Bronx River for 1 1-2 miles and will accommodate six cars abreast.

The Long Island Automobile Club is preparing for its race meet scheduled for November 16. In the entry blank gasoline carriages are divided into three classes: under 1000, between 1000 and 2000, and over 2000 pounds. Steam vehicles of all kinds are to compete in one class, as will electrics.

Two destructive fires marked the week. One, at the Chicago plant of the Woods Motor Vehicle Company, caused a loss of $75,000. The other, at the new establishment of the New York Belting & Packing Company, also caused a large loss.

Digest of the Leading Foreign Papers

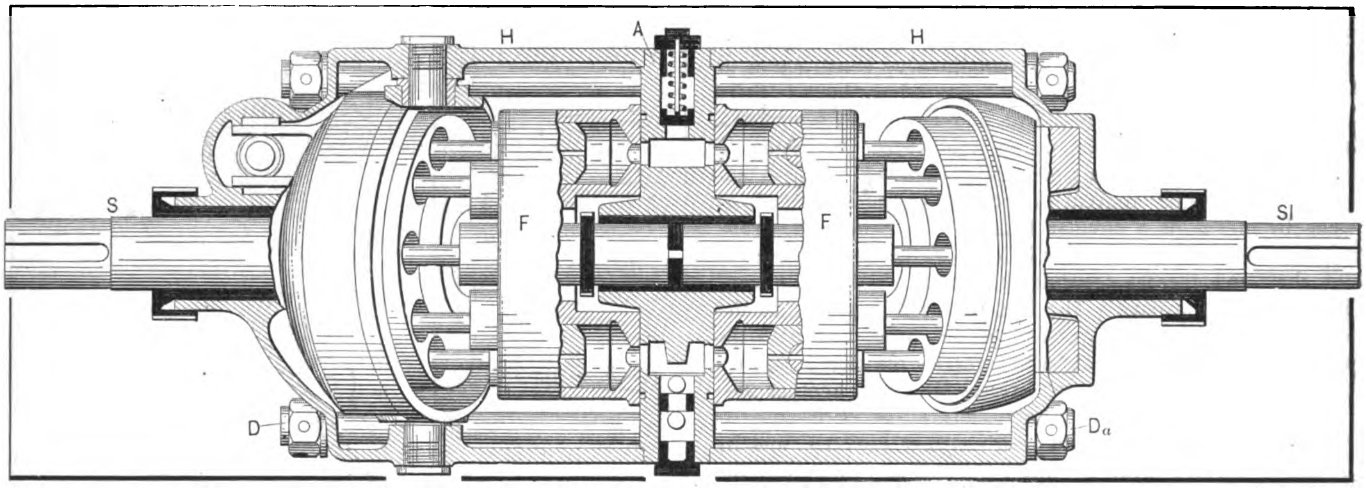


Fig. 1—Delaunay-Belleville hydraulic change-speed set in which oil is used

New Hydraulic Change-Speed Set

THE Williams-Janney hydraulic transmission and change-gear mechanism, which has been used for the maneuvering of turrets and large ordnance on board of warships, has been adapted to automobile purposes by the Delaunay-Belleville Company, of France, and is described by C. Faroux in a review of the foremost hydraulic transmissions, as these have become known through patents or practical applications. In all of them the principal object is simplification of the driver's control movements, the avoidance of gears and such reduction of the vehicle speed that a motor of moderate size shall be sufficient for moving a heavy load under the most difficult conditions of haulage so long as road adhesion is obtainable. The leading features of the mechanism are as follows:

The casing, Fig. 1, is formed of halves H bolted together against a central transverse plate A, called the distribution plate, in which there are two crescent-shaped slots (see Fig. 2). The motor shaft S enters one end of the casing through a packing box and abuts against a thrust block in the middle of the distribution plate, where a bushing in bearing metal is provided, and the driven shaft S, also abutting against this thrust block, extends through a long-packed bearing at the other end of the casing. Except as noted in the following, the parts are symmetrically alike on both sides of the central plate. A drum F keyed to the motor shaft adjacently to the central plate, is provided with nine cylindrical bores which register partially with the crescent-shaped slots in the central plate, except that each of the cylinder bores when at the top of the circle of rotation must register with the solid portion of the plate between the slots. In this drum nine reciprocating pistons, Fig. 3, are moved to and fro by means of piston rods actuated by a plate mounted upon the motor shaft by a cardan joint and held in an oblique relation to the motor shaft by its confinement in the ball-bearing ring, with large end thrust bearing balls in which it rotates. The adjustment of the cylinder drum on the motor shaft by means of rounded splines permits a certain play, two helical springs secured to a pin through the motor shaft holding one end of the drums against the central plate when the mechanism is started. When the oil, which fills the whole casing, is under pressure in the cylinders, the drums D and the central plate are automatically held in contact because the interior pressure exceeds the exterior by virtue of the piston area exceeding that of the cylinders. The ball-bearing plate, on the motor side of the mechanism, may be placed at any angle between 90 deg. and 70 deg., as the ring or cup in which the ball bearings are mounted may be turned around pivot pins journaled in the casing by means of a control device consisting in a threaded rod actuating a worm. The adjustment screw passes through a packing and is operated by a lever from the outside. The ball-bearing plate on the driven side, on the other hand, is caused to rotate in a ring whose relation to the shaft is fixed permanently at an angle of 70 deg.

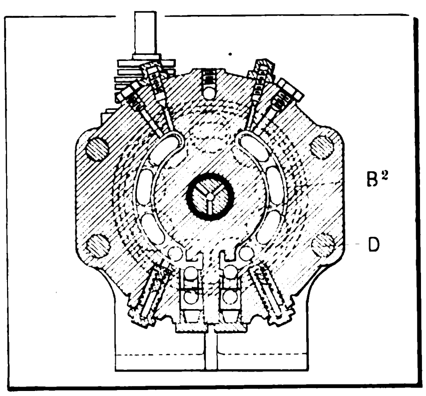

Fig. 2—This is an illustration of the central plate A, shown in Fig. 1, and shows this plate as seen from either end of the change-speed set. The two crescent-shaped slots spoken of in the text are seen, as well as the solid portion of the plate between ends of these slots

In operation, when the motor shaft rotates the drum on the motor side, the ball-bearing plate, rotated in its oblique ball bearings by the cardan joint and acting against the ends of the piston rods, drives the pistons in or out of the cylinders accordingly as the piston rod's attachment in the ball-bearing plate moves obliquely toward the distribution plate or away from it, and these movements of the pistons on the motor side of the mechanism are transmitted through the oil in the cylinders to the pistons on the driven part of the mechanism, this piston movement in turn causing the driven ball-bearing plate to rotate in the direction which will make room for the piston movement similarly as a sailing vessel is driven forward, following the line of smallest resistance in the direction of its keel by a side wind, though the latter acts at right angles to this direction. The driven ball-bearing plate, of course, carries with it the cardan joint upon which it is mounted and thereby the driven shaft as well as the cylinder drum on the driven side. The speed of this rotation of the driven shaft is approximately the same as that of the motor shaft only if the motor pistons are allowed full stroke, as in that adjustment of the ball-bearing plate on the motor side which is indicated in the illustrations. But if this plate is raised to a position more nearly parallel with the distribution plate each of the motor pistons will displace less oil for each revoution of the motor shaft, and the rotation of the driven ball-bearing plate will be correspondingly retarded, since the pistons on the driven side must always move with full stroke.

To effect a reverse movement of the driven shaft it is only necessary to tilt the ball-bearing plate on the motor side in the opposite direction, as this will reverse the piston movements and therewith the direction of the driven shaft's rotation. The solid portion of the distribution plate between the two crescent-shaped slots, Fig. 2, corresponds to one of the two periods in each revolution of the mechanism when a given angular movement in the rotation of the ball-bearing plate on the motor side is represented by only a negligible amount of travel for each piston, and the interruption of the oil flow through the slots at this point therefore serves to prevent uncertainty in the direction of motion communicated to the driven ball-bearing plate.

It is noticed that the only part of the oil which works in this hydraulic transmission mechanism is that contained in the cylinders and in the slots of the central plate A. The rest is not under pressure, but serves to lubricate all parts and to supply losses due to leakage, a reservoir with suitable valve passages to the casing keeping the latter full and taking care, as well, of expansions and contractions due to changes in temperature which may affect the oil and the casing unequally. Oil channels through the piston rods and pistons, which, however, are almost closed where the end of the rod abuts against the bearing socket in the ball-bearing plate, serve to remedy irregularities which may arise if some of the working oil in the cylinders is driven out under excessive pressures. These may occur in case of very heavy loads, when the ball-bearing plate on the motor side is adjusted to a low-gear position nearly parallel with the drum and the central plate. There may then be some escape of working oil between the pistons and the cylinder walls. It is evident that the walls of the central plate need not be parallel or close together. The space represented in the slots of the central plate may take the form of a long connecting tube and the driven part of the mechanism may be apart from and at right angles with the motor part. In principle the construction (and the patent) is relatively old and only the adaptation to it of modern ball bearings, highly accurate workmanship and a number of minor refinements, some of which may be discerned in the illustrations, have rendered it practical.—From *Bulletin de la Société pour l'Encouragement des Industries Nationales* for May and *La Vie Automobile,* Sept. 23.

No Conspicuous Aeroplane Improvements Shown in France —At the competition for military flying machines taking place at Rheims, in France, the principal innovations in features of construction are the offset planes on the Maurice Farman biplane (so that the upper plane is not vertically above the lower one), and the improved starting and landing skids on the Coanda machine. For the military tests which relate largely to the carrying of loads, safe landings and starts from difficult—confined or rough—ground, the biplanes are considered much superior to the monoplanes. For speed the reverse is considered to have been established as true, for the present. Nearly all the motors have a considerable excess of power, to be used for emergencies only. In other words, it is recognized that no internal combustion motor can be normally operated at the extreme of its power capacity without incurring too many chances of breakdowns. The motors shown, in addition to the well-known Gnome, Renault and Anzani models, are the Clerget, the Chenu, the Dansette, which are modified automobile motors, and the Canton-Unne with radiating cylinders. To rise from a ploughed field by the shortest run and to reach an altitude of 500 meters in less than 15 minutes are the two performances under competition.—From *L'Auto,* October 13.

Bends of the road have become dangerous to night-drivers since tar has been used as a dust preventive. Formerly the roadbed shone white in the light of the headlights, and, in case of a bend, the white streak was apparently interrupted fifty or sixty yards ahead, warning the traveler, but now the highways are black; the tarred surface simply devours the beams of the lamps and the metalled track seems to merge imperceptibly into the grass verges, and even the hedges that bound the roadway. When an abrupt turn is approached there is great difficulty in realizing the fact.—From *The Royal Automobile Club Journal,* October 13.

Where rain-water drains from tarred roads into fishing preserves, especially those in which salmon or salmon trout are hatched, great injury to fish life is said to result. The *Fishing Gazette* of July 8 reports a complaint from the Northern Anglers' Association relating instances in which damage was due to this cause and citing one case in which 17 pounds of poisoned eels were collected.—From a discussion in *The Royal Automobile Club Journal,* October 13.

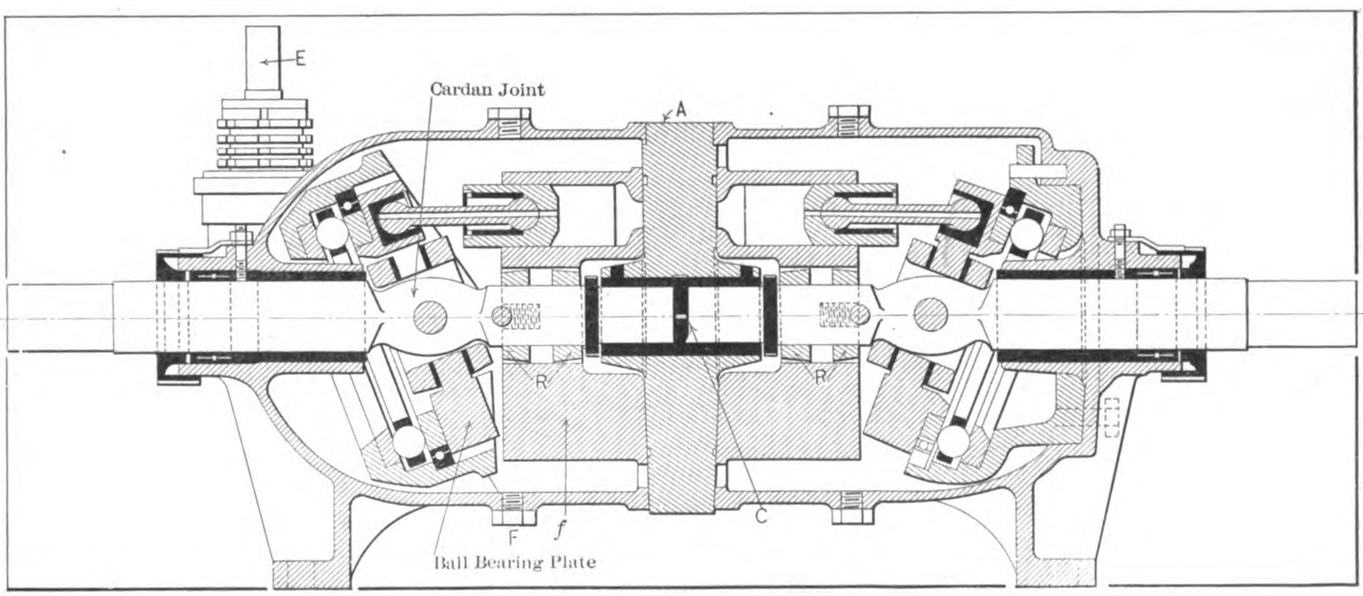

Fig. 3—This is a vertical section of the Delaunay-Belleville hydraulic change-speed set for use on trucks and lighter commercial vehicles. The central plate A is seen, also the ball-bearing plates mentioned so frequently in the text. The sets of pistons which work in cylinders in the drums D can also be seen, as well as the two cardan or universal joints spoken of

Letters Answered and Discussed

Has Carbureter Troubles

Editor THE AUTOMOBILE:

[2,889]—I am a subscriber to THE AUTOMOBILE, and would like some information regarding my car. I have a 30-horsepower automobile with a double-ignition system and single set of spark plugs. The car pulls very well on level ground, but as soon as I get on a hill the motor speeds up fairly well until I open the throttle wide, when it will suddenly stop without missing an explosion otherwise.

I have had the carbureter cleaned and adjusted for gasoline and air without results. I have also had the float shellacked and the gasoline pipe examined, but the carbureter will leak a short time after it is stopped. I have also had magneto points cleaned, and the other parts of the ignition system seem to be all right. F. H. C.

New Village, N. J.

The carbureter chokes when required to give a good supply of air when it is most needed. This can be remedied in two ways. First, by buying a new carbureter which has better auxiliary air adjustments; and second, to fit an air adjustment on the intake pipe which can be opened and closed by hand from the seat.

Testing Spark Apertures

Editor THE AUTOMOBILE:

[2,890]—I have had considerable trouble with the ignition system on my car and have after considerable time come to the conclusion that it is due to the fact that the gaps in the spark plugs of two of the cylinders are too wide. How is it possible to test them for the correct distance between the two points?

I am sure the trouble is merely in the spark plugs, for if I take the other plugs out and put them into these cylinders, they will fire all right. I was about to purchase new spark plugs, but thought that I would ask you if it would be anything besides the spark plugs which would cause trouble of this nature. T. T. T.

Hot Springs, Va.

It is a very simple manner to squeeze the spark-plug points together with a pair of pliers. A good method of testing the spark plugs is to take a dime as shown in Fig. 1. If the gap is too large, the dime will pass between the two points.

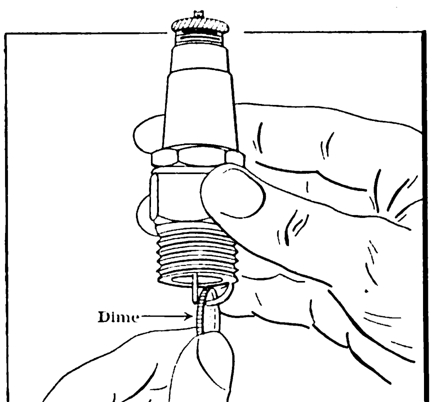

Fig. 1—Handy method of testing spark plugs to see if space betwen the spark plugs is of the proper width

Locking Turnbuckles

Editor THE AUTOMOBILE:

[2,891]—Would you kindly tell me if you know of any method of locking turnbuckles so that the vibrations due to the engine or road will not alter the adjustments upon them?

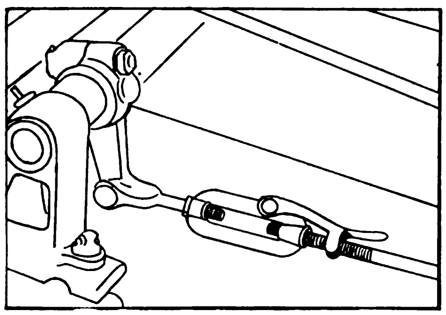

Fig. 2—Showing a simple method of locking turnbuckles

The turnbuckles on the brake equalizers come out of adjustment after I have been running for a time, and if there was some simple method of locking them which I could install upon the buckle myself I would greatly appreciate it if you would tell me how it is done. B. BUNN.

Carthage, N. Y.

A simple method of installation is shown in Fig. 2. The clamp is merely turned back and holds the threads on the rods by means of corrugations in its jaws. A spring or other device may be fitted to keep it in position.

Information on Farm Motors

Editor THE AUTOMOBILE:

[2,892]—In your issue of October 19 you have an article on motor farm machinery. I refer to the article on page 674. Can you inform me where I can get descriptive matter on the machinery therein mentioned together with prices. I am interested in motor machinery for farm use and will be greatly obliged for any information you can give me. Very sincerely yours,

Fitchburg, Mass. THOMAS CASEY.

The C. I. M. A. tractor is made by the International Harvester Company of France, just like those made by same company here. With regard to the others we would refer you to Association Française de Moto-Culture, 51 rue de Lancry, Paris.

Wants Gasoline Information

Editor THE AUTOMOBILE:

[2,893]—Would you be so kind as to answer the following questions:

(1) What grade of gasoline should I use to get the best results?

(2) How is it possible to determine the grade of gasoline from a given sample?

(3) What is the wholesale price of the different grades of gasoline?

Muscoda, Wis. C. R. PICKERING.

(1) The best results would be obtained with the lightest grade of gasoline, but excellent results are obtained with gasoline which registers 76 per cent. on the hydrometer test—the best grade of gasoline now in common use on the market.

(2) By means of the hydrometer, which is a very cheap instrument, and on sale at any supply house.

(3) The wholesale price of gasoline varies. At the present writing it is quoted at 7 cents per gallon in wooden barrels for 76 per cent. gasoline.

Repair Broken Crankshaft

Editor THE AUTOMOBILE:

[2,894]—Being a reader of THE AUTOMOBILE, I would like to ask if it would be possible to have a broken crankshaft repaired that was made by a concern now out of business. These people have ceased making parts for their automobiles and hence I cannot have it replaced.

Bradford, O. ROY L. MILLER.

The crankshaft may be easily repaired, unless it is a hopeless wreck, by the autogenous or oxy-hydrogen welding process. Any firm who does this work will tell you if it is possible to repair your crankshaft.

Kerosene in Radiator

Editor THE AUTOMOBILE:

[2,895]—Would you kindly tell a weekly reader of THE AUTOMOBILE what the result would be if kerosene were placed in the radiator instead of water?

Findlay, O. FRANK CONE.

The result would be that you would be

paying for your cooling fluid instead of getting it for nothing; that it would only cool your engine 87 per cent. as well as the same quantity of water; that various gases would be given off which would issue from any loose connections and that it would leak very easily. In short, it would not be very advisable to use it.

Wants Heavier Flywheel

Editor THE AUTOMOBILE:

[2,896]—I would greatly appreciate it if you would answer the following questions through the columns of THE AUTOMOBILE:

(1) Is it safe and possible to increase the weight of the flywheel on my car, say about 15 pounds, without danger of damage to the engine?

(2) Where can I have aluminum castings made? A. W. MILLER.

Bound Brook, N. J.

It is not very easy to place additional weights on the flywheel owing to adjoining parts and other complications. But the counter-weights illustrated in Fig. 3 may be bolted on the cranks. If this is done the weights must be carefully distributed and arranged so that the balance of the engine will not be destroyed. In a four-cylinder motor with the cranks cast in pairs, there will be, as a rule, but three main bearings. In this case the weights should not only be distributed evenly among the cranks, but should also be balanced on either side of the center main bearing. The weight should add up to the total required. It must be remembered that when they are bolted so closely to the center of rotation, a heavier weight may be fitted than when they are at the rim of the flywheel. Fifteen pounds at the distance of a foot from the center of the shaft would be equivalent to 90 pounds at 2 inches from the center.

Any foundry will make the castings for you. If you consult a trade directory you will find the names and addresses of several.

Wants Wiring Diagram

Editor THE AUTOMOBILE:

[2,897]—I have a 12-volt battery set, and wish to light two 6-volt lamps and also start the motor on the same batteries with four-section coil. Would you please give wiring diagram? SUBSCRIBER.

Indianapolis, Ind.

The wiring diagram is given in Fig. 4. As the coil will probably be wound for 6 volts, a 6-volt wire will have to be led from the battery set, on a separate switch from the lamps.

Vanadium as Scavenger

Editor THE AUTOMOBILE.

[2,898]—The controversy with Mr. Lake has already taken up so much of your space that I am reluctant to further encroach. Mr. Lake assumes that the prominent metallurgists I named as investigators of vanadium steel "have doubtless accepted Mr. Smith's statement that vanadium was a powerful scavenger." Possibly they have, although there is no evidence in any of their writings to that effect. My contention is not that vanadium does not possess scavenging value, but that this is not its main mission, and there is absolutely no evidence in any printed matter on vanadium by any competent metallurgist "that its main mission is as a scavenger." Mr. Lake says that of the metallurgists mentioned, J. Kent Smith was the only one who has specialized on vanadium, and that the property of vanadium as a scavenger "was the only statement that Mr. Smith emphasized." To refute this latter assertion I quote from the discussion on an address he gave before the Association of Licensed Automobile Manufacturers in New York City March 7, 1907:

"MR. ELWOOD HAYNES.—I would like to ask Mr. Kent Smith one or two questions. Secondly, whether it is essential for any of the vanadium to remain in the vanadium steel in order to give the special properties of vanadium steel?

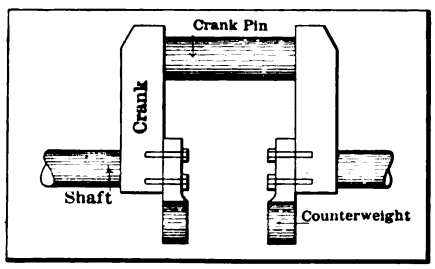

Fig. 3—Illustrating how counterweights are bolted on cranks

"MR. KENT SMITH.—With regard to the question as to whether it is necessary for vanadium to remain in the steel, I answer that strongly in the affirmative. Vanadium is an 'elusive' element. If there is any oxide left in the steel the vanadium will scavenge it out; but vanadium is an expensive scavenger. You want your vanadium left in to both statically intensify and to give dynamic quality to the metal."

Dr. Mathews' very favorable comments on vanadium steels before the Franklin Institute were made more than a year later than his talk with Mr. Lake, and after he had the opportunity to investigate and test out vanadium steels himself. Possibly Dr. Mathews' criticism was directed more towards Mr. Lake's handling of the subject. Dr. Mathews' opinion of vanadium steel is still the same as it was in 1909 when he delivered his lecture at the Franklin Institute. Mr. Lake stands alone and opposed to the experience of the steel makers who have made thousands of tons of vanadium steel, when he says that "its main mission is that of a scavenger." When he says, "I might say I know of none who have said that the main mission of vanadium is not that of a scavenger," he seems to be ignorant of the literature on the subject, for there is absolutely nothing published to warrant such a statement.

GEORGE L. NORRIS.

Pittsburg, Pa.

Broken Valve Stem

Editor THE AUTOMOBILE:

[2,899]—I have recently been troubled with an inlet valve that broke on the road. Had it not been for a near-by shop I don't exactly know how I would have got home. Can you tell me of a way of repairing such damage on the road? J. O'DEA.

Jamaica, L. I.

You could have reached home by closing the inlet port whose valve is broken. It is also advisable to close the exhaust port to prevent scale and dirt from being drawn in through the exhaust pipe. The ports may be closed with a piece of thin sheet metal placed between the pipe and motor; or in some cases the valve lifter can be removed and the valve blocked down by removing the cap over it and placing something between the cap and the valve, putting the cap in place again to hold the valve down. It is generally better to have an opening into the cylinder after the ports have been closed, such as may be made by the removal of the spark-plug. After fixing this the engine will run on the remaining cylinder.

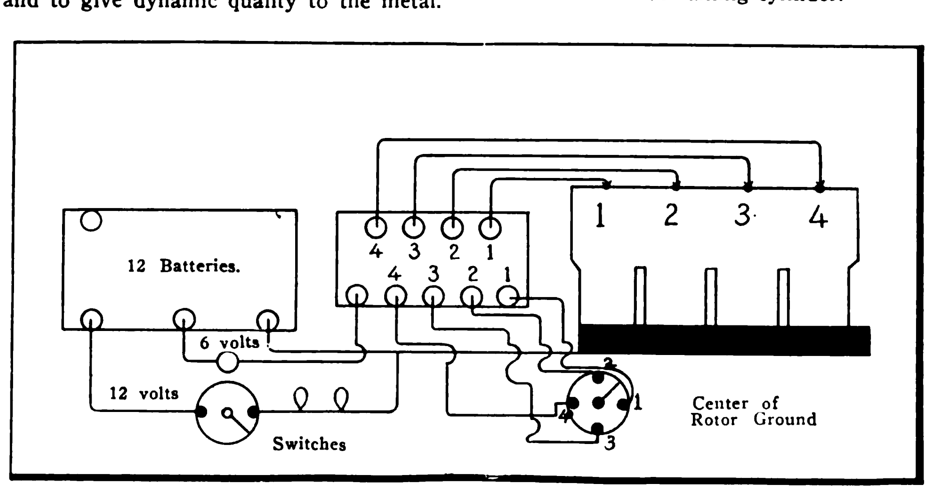

Fig. 4—Wiring diagram showing how to light two 6-volt lamps and start the motor on the same batteries

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

MEASURING THREADED PIECES—In the replacement of parts it often becomes necessary to measure the threading on a pipe or other part of the mechanism in order to properly describe to the maker the part desired. It is not always the case that a repair will be made by the service department of the company from which the vehicle was purchased, as there are not many people who maintain repair stations at distant points. In such cases the part will have to be sent for, and the long delay which accompanies the delivery by express or freight of heavy parts will have to be sustained. In many cases what would be a very simple and quick replacement for the service department or factory becomes a matter of very serious delay in the case of a person who is on an extended tour which carries him far from a place where speedy repairs or assistance could be expected.

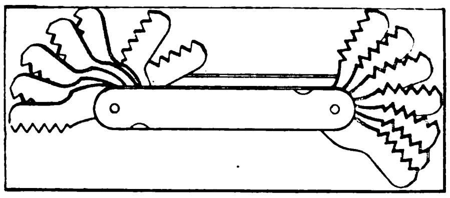

Fig. 1—Handy tool for measuring number and depth of threads

The tour, even though it be extended, would have to be very exceptional if it was out of fairly short reach of a machine shop or a plumbing establishment. It might not be possible to reach such a place with the automobile in case it should have been completely disabled; but it would not be impossible to telegraph to the plumbing shop or machine establishment the nature of the piece required and have them be busily occupied in making it while the owner of the car either takes the train to the place of manufacture or awaits its arrival by express. If this is possible the wait will be merely one of hours for the repair instead of one which might necessitate an interval of several idle days.

It is not always possible for the amateur tourist to describe the part which he needs in language which is intelligible to the trained mechanic, who has a technical name for every contrivance upon which he works or every part which he turns out. But with the aid of the instrument shown in Fig. 1 the average car owner can, without an extended study of machine shop practice and its accompanying details of technical nomenclature and other stumbling blocks in the way of the very excusably uninitiated, at least tell the thread dimensions on a threaded piece of material which needs replacement. A small tool of this nature is extremely handy, and this alone goes far in justifying it a place in the repair kit of the traveler who is going to make an extended tour, even if he starts out with a strong determination to cut down all excess baggage and weights which might interfere with the comfort of the passengers. But when the claim for space in the kit of the tourist is backed up by the fact that it might prove a friend in need, when the car is far from headquarters, it should at least be carefully considered before being thrown into the discard.

To measure the threads, the different leaves of the instrument are opened in the same manner as the blades of a pocket knife, and successively tried in the manner depicted in Fig. 2 until the proper blade is found. The number of teeth to the inch and the depth of the thread are marked upon the leaf of the tool and may be read off very easily. These dimensions are all that is required besides the specification of the shape of the thread, whether it is of V shape or whether it is square.

measure the thread by putting the inch marks from root to root.

In case it is desired to measure the thickness of the shaft at the bottom of the threads it will be necessary to calibrate it by means of special calipers, called thread calipers, which are made for this special purpose—Fig. 4. The art of amply describing mechanical parts in language which will be familiar to the shop man is not a simple one to acquire. This is more particularly the case because localisms take the place of the true names of parts, and it is almost an impossibility for a machinist to understand all the terms of another who comes from a distant shop. In no case is this illustrated better than with the draftsmen of the different large machine shops in the country. A draftsman changing from one concern to another will often be put at practice work for the space of one or two months until he will have perfectly mastered the style and terms used in connection with the work at his new place of employment.

If this is the case with men whose profession leads them to study the delineation of mechanical parts and their various necessary dimensions it is very evident that it will necessarily trouble those to whom the more intricate details of the work in hand are unfamiliar. It is for this purpose

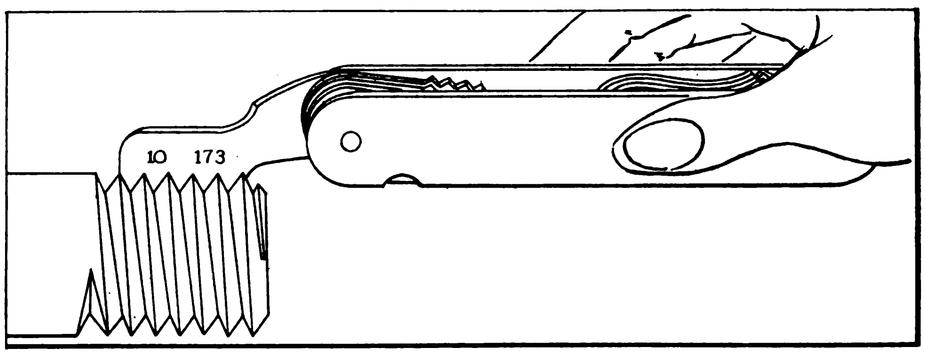

Fig. 2—Showing the manner of measuring a threaded bolt with a pitch gauge to ascertain size and depth of thread

If the style of thread be known to the operator all that would be required in amply describing the part as far as the thread is concerned would be to determine the number of threads to the inch by means of a steel rule or by any other rule which may happen to be convenient. The rule is laid upon the threads in the manner shown in Fig. 3 and the threads can be counted. In measuring the threads it is best to put the inch marks upon the apex of the thread instead of attempting to

that special instruments, with which to determine the necessary and standard dimensions, are required. It may be the case that they will not be required once in three years, and again circumstances may be such that they will be found of frequent use. Standardization is only of recent years finding its way into the mechanical world, and confusion still reigns to a slight degree, although conditions are far better so far as interchangeability is concerned than they were a decade ago.

It is possible for the car owner who is equipped with these small but useful devices to go long distances with a feeling of security which springs from the knowledge that in case an accident should happen he is at least prepared to get out of it as gracefully as the circumstances will permit, and that the delays which accidents entail will be reduced to a minimum. It is not to be recommended to carry about a quantity of loose material which generally receives the ignominious appellation of junk, but the small articles which may save trouble should be well considered.

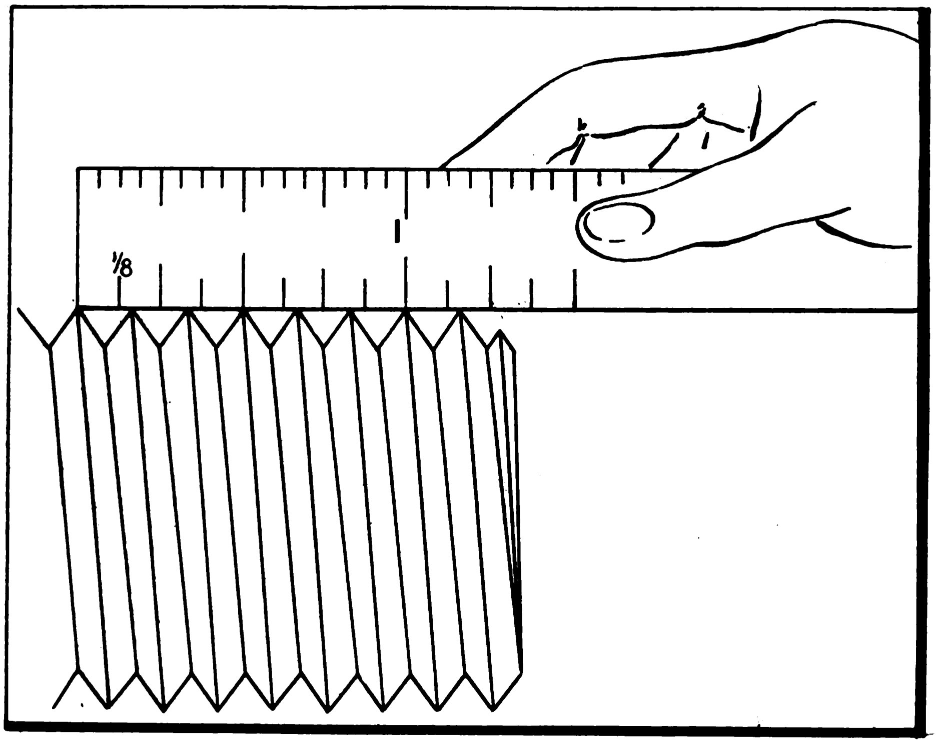

Fig. 3—Showing proper way to ascertain number of threads to the inch on a bolt

Examine Tools Before Starting—Besides carefully going over the finish of the car to see that it will do its owner credit on little trips around the country, it is extremely advisable to examine into the condition of the tools which are carried before starting out. There is no possible way of foretelling the conditions which may arise upon a trip even though it be of short duration. The best of cars will develop small weaknesses or derangements which may be readily cured by the use of the most familiar tools. If these tools are not in a fit condition to perform their work these small incidents will develop into annoying features which will spoil the pleasure of the tour on the most pleasant of days.

The chief enemy of tools is rust. Moisture, with its accompanying evils, will find a means of access to the tool kit if it is not very carefully sealed against the inroads of this enemy of most metals. A small coating of good oil, which can be placed so thinly on the metal that it will be hardly perceptible, will protect a tool to such an extent that the little trouble which it involves will be too small to consider. The oil may be placed upon a cloth in such a way that the cloth will be saturated. If the tools are then wrapped in the cloth they will be very safe from anything short of a deluge.

It is remarkable how tools and other metallic instruments subject to rust may be ruined by the moisture carried in the air, especially near the seashore or in other places located near a large body of water, and hence carrying in suspension a great amount of aqueous vapor. In case the machine is to be left standing for any length of time in a neighborhood where it is likely to be exposed to the sea air, proper precautions should be taken not only to keep the tools in good condition, but also the other parts of the car which are not protected by paint or some other preparation to eliminate the possibility of oxidation.

The tools in a garage which is located in a damp climate will also require a considerably greater amount of care than those kept in a place which is high and dry. For this reason these tools require frequent attention and care in order to keep them in first-class shape. The cutting edge of a sharp tool, when examined beneath a microscope, will be seen to consist of a number of serrations similar to the teeth of a saw. When the edge is attacked by rust these small teeth are filled by the particles which gather upon the cutting edge of the knife or chisel, which is thus practically ruined. If the blade of the tool is protected by an oil or some other preparation which will defeat the effects of moisture the life of the tool will be greatly prolonged, and the necessity for a rigid examination at the start of every trip will be removed at least to a large extent.

Loose Exhaust Manifold—A peculiar wheezing sound which at times will almost approach a whistle may often be heard issuing from the motor. A search will often be made without results on account of the concealment of the source of trouble. It will usually be a safe guess that the sound issues from a point in the exhaust line where the piping has opened into a leak. As the gas under a pressure of 30 pounds, or thereabouts, rushes past the opening, a small amount passes through the opening, giving vent to the sound, which will often prove most elusive.

If a leak is found in the intake line it is not accompanied by the same noisy features that will insure detection of leaks in the exhaust line, but will be accompanied often by the blow-backs occasioned by a mixture which is too weak. The suction of the engine will naturally draw a quantity of air through the opening, thus diluting the charge and giving rise to the symptoms generally accompanying the lean mixture.

The chief cause of leakage in the exhaust line is the vibration of the engine, combined with the crumbling of the gasket, which keeps the joints tight while it is in good condition. In spite of the fastening which holds the flanges tightly together the constant shaking of the engine, which will be present, no matter how well balanced it may be, will cause the two flanges to work

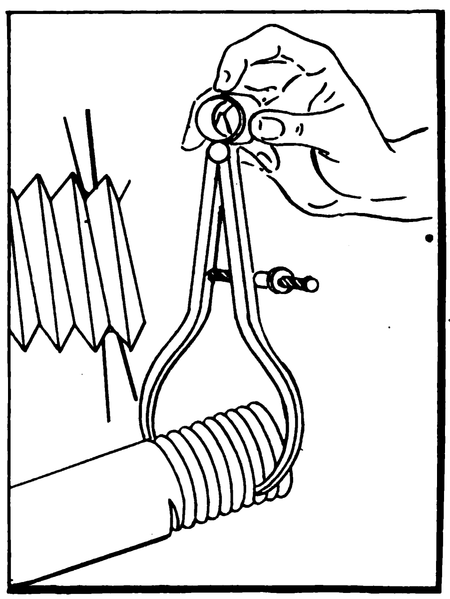

Fig. 4—Showing how to use calipers in determining the dimensions of thread

upon each other. This, combined with the high temperature present at this point in the line of the engine, will cause the packing or gasket to harden and eventually to crumble as the length of time it is submitted to wear increases.

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

Had Broken Steering Column

EDITOR THE AUTOMOBILE:

In accepting your invitation to relate road experiences, the writer has selected a case which was quite serious, although it may not be classed as a "road repair" in the strict sense of the term. The repair was, however, made 225 miles from home and with such facilities as were available.

The accident, which happened on a very sandy stretch of road in Wisconsin about 3 miles from the nearest town, consisted of the steering column breaking off short and complete, carrying with it all control.

This steering gear (Fig. 1) is of the screw and nut type, and the screw has an integral extension 3/4 inch diameter extending about 4 inches into the lower end of shaft of steering wheel, and pinned to same by means of two 1/4-inch taper pins, B and C (Fig. 2). The extended portion of screw broke through first pinhole C, as indicated in Fig. 2, the holes being through center of shaft.

Upon examination of fracture it was found to be an old break which was continued to destruction, as shown at A.

The balance of steering gear was removed from car, which was left at side of road, and carried back to the town through which we had recently passed, in the hope of finding something that looked like a machine tool. In this the writer was partly successful, as a country tinker shop was found which contained a small lathe which would at least revolve. The man in charge of this place granted permission to use this lathe; thereupon, the gear was disassembled and the broken member drilled, as indicated in Fig. 3, and a piece of 3/4 common round iron G inserted and pinned in screw, as shown at I and I. These pins were ordinary wire nails. The other end was secured as before, except that straight pins, consisting of 1/4-inch round iron, were used, nothing else being available.

The whole was then reassembled and carried back to the car (on foot) and placed in position and connected up, the journey then being resumed. The total time occupied was 4 1/2 hours, cost $2.70.

For the first 100 miles no chances were taken, and no avoidable strain put upon the repair, but as there was no evidence of weakness, confidence gradually returned, and car was run continually for 3 months with this temporary repair, and when same was finally removed for permanent repair, as indicated in Fig. 4, it was found to be serviceable. The permanent job was, of course, of proper materials and is still running.

This repair having been the most interesting one I experienced, I have related it alone here. Judging from the other quick jobs, which I have found occasion to execute, at some time or other, it seems to me that a repair may in a good many cases surpass the original piece in strength and serviceableness, at least for some time. It probably is not too rare an occurrence that the mechanical ability of the car user exceeds that of a designer, especially where some apparently insignificant details are cerned.

Chicago, Ill. H. R. WILLARD.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Specifies Underslung Frame

EDITOR THE AUTOMOBILE:

One important factor of an ideal motor car, in my estimation, should be its safety. To secure this I would specify an underslung frame, which has been time-tried, and has proven itself to be the safest construction.

The front axle should be a one-piece, drop-forged I-beam, and instead of having forked ends it should fit into forks integral with the spindles, thus weakening the axle in no way. The spring seats should be made integrally with the axle.

The cross-steering rod should be in the rear of the axle and be a drop-forged I-beam. The cross-steering rod, axle, spindle, arms and knuckles should be of chrome nickel steel and all wearing parts supplied with grease cups and simple adjustments. The steering gear should be of the worm and sector type, the housing being bolted to the frame. The steering column should be bolted to the motor sub-frame by means of a rod. The steering wheel, 20 inches in diameter, with a corrugated hard rubber rim, and with the spark and throttle levers fixed above it.

The motor should be a three-point suspension unit-power plant, six cylinders, cast in pairs of two, 4¾-inch bore, 6-inch stroke, 2-inch valves in head, with easily removable cages, four-bearing crankshaft, cams cut integrally with a four-bearing camshaft placed on right side of motor; valve tappets with rollers and fittings in the guides with a square fit, and the entire valve system, *i. e.*, rocker arms, push rods and tappets, should have simple adjustments for wear. The pistons should be dome-shaped, having four rings and the wrist pins held in place by both.

The ignition system should be of the double type, magneto, storage battery and two sets of spark plugs placed on the left side of the cylinders. Also the magneto and the battery distributor should be on the left side, thus making the wiring connections very short. The magneto should be an Eisemann, with a non-vibrator coil, and the battery should have a vibrator coil, both easily removable for inspection.

The cooling system should consist of a Livingston radiator in connection with a centrifugal pump driven by the magneto and battery distributor gear and an eight-bladed aluminum fan driven by a worm gear.

The lubrication system should be a gear-driven pump contained in the lower half of the aluminum crankcase (which is also the oil reservoir) forcing oil to all crank and camshaft bearings and the gears; and a constant level splash system for the crank and wrist pin bearings and the cylinder walls.

The gasoline system should be of a force feed type, with a pressure release, driving gasoline from a 30-gallon tank on rear of car, through a No-chammy strainer to a water-jacketed Rayfield carbureter (which has proven to me by experience that it can produce a perfect mixture at all speeds and under all conditions, and still economize on gasoline) placed on left side of motor.

The magneto and camshaft gears should have oblique teeth and be placed in front part of crank case.

The flywheel should be at the rear end of the crankshaft and enclosed in the unit housing. The clutch should be multiple disc, running in oil, with 26 steel driving plates and 25 bronze driven plates.

The gearset should be selective sliding and have three speeds forward and one reverse.

The steering mechanism should be on the left. The clutch and service brake, operated by left-foot pedal, and the emergency brake operated by right-foot pedal. In this way the change-speed lever is permitted to be in the center and it should not be operated in an H-slot but in a short cylindrical column, with a ball and socket joint, since the lower end of the lever would fit directly into slots in the gear-changing shafts. This control, along with a foot accelerator, should make one of the simplest controls.

There should be but one universal joint just back of the transmission, for the underslung frame would supply a straight line drive.

The rear axle should be floating and have a supporting member of one-piece drop forging, extending clear to outer ends of hubs. The center of this forging should be a large ring, in which the differential and bevel-drive would be supported on large ball bearings. On the forward face of the ring should be bolted a housing completely enclosing the tail shaft. A semispherical plate at the rear would encase the differential and by having a plug in it would supply a very accessible means of putting grease in the housing. By the removal of the above plate the entire differential and bearings could be removed. The axle shafts should have eight-jawed flanges which fit into notches on the wheels. The supporting member should also provide bearing surfaces for swivel spring seats. The radius rods should be I-beam drop-forgings.

The front springs should be semi-elliptical, 36 inches long, 2 inches wide and 8 in number. The rear should be semi-elliptical, 56 inches long, 2½ inches wide, 10 in number and of the Packard type of connection of the rear end to the frame. All springs should be assisted by shock-absorbers and all spring bearings fitted with grease cups.

The brakes should be four in number, enclosed, internal expanding, 18 inches in diameter, 2 inches wide, giving about 452 inches braking surface, and all brake mechanism between frame members.

The wheels should be large enough to be fitted with 42 x 4½ I. D. tires, should have demountable rims and spokes of second-growth hickory. The front wheels should have 12 spokes, and the rear 14, each of which is bolted to the brake drums about 2 inches from edge of hub flanges.

The body should be a four-passenger torpedo, sheet-metal, with wood frame, fitted with 10-inch upholstery, trunk rack, running-board battery boxes and tool kit, and tire rack for two tires and rims.

The equipment should be: Combination Klaxon horn, compressed air starter, engine tire pump, complete set of tools, Warner speedometer and clock, Gray & Davis lighting system with side lights flush with the cowl dash, and mohair top and seat covers.

Wheel base should be about 124 inches.

This car should cost about $4,000, as I agree with Mr. Louis Bourgeotte, in your issue of October 15, and believe that such a car as I have described cannot be built, with the best materials in all parts, such as silico-manganese steel springs, for less money. FRANK R. SCHUBERT.

Barberton, Ohio.

Wants Nice Little Car

Editor THE AUTOMOBILE.

Availing myself of your offer of outlining my ideal of a car, would say that I would prefer a small car for two passengers, roadster type, with fore-doors, about 106 inches wheelbase, with a motor permitting the car to go easy on say 20 miles an hour. I believe in a chain drive, live axle, 34 by 4 tires, and above all, high-grade workmanship and material. Such a car, if sold for $500, could be manufactured by the myriad. FRANK WHITNEY.

Buffalo, N. Y.

Review of 1912 British Models

LONDON, Oct. 20—The first point that presents itself for consideration in regard to next year's cars is the matter of engine design, and the first subdivision of this section relates to the valve system. It is truly an extraordinary thing to find that after all the ingenuity and skill expended on the invention and design of new valve methods, the field is still left free for the poppets on one side and the Knight sliding sleeves on the other. As far as the sleeve-valve engine is concerned, its popularity is steadily increasing. The Daimler Company has not produced a poppet engine for 3 years, and the management declares that it desires nothing better than its present Knight engine. Incidentally, the Daimler output this year is the largest of any European firm. In addition, the following licensees of the Knight engine do a big business in Great Britain: the Rover Company, the Belgian Minerva, the German Mercedes, and the French Panhard. It would probably be correct to say that one car in every five sold has the sleeve-valve engine. This proportion is likely to be bettered next year, for two new licensees will be found in the Deasy Company, which has Mr. Siddeley, a leading British designer, at its head, and the B. S. A. firm (the gun and small arms factory), which will produce a small car of 14 horsepower, selling at about the $1,750 mark.

But, while the Knight engine is popular with a big section of the community, it must be agreed that the present-day, poppet-valve engine, as made by the best firms, has had so much attention paid to the silencing of its details that it is, for all practical purposes, quite as silent in operation as the sleeve-valve type. Spring-actuated tappets, greatly reduced clearances, stout cover-plates across the valve mechanism, and other devices, have repaid their cost by the almost complete muffling of noise. The valves silenced, other engine noises have been disproportionately obtrusive, and the silencing process has had to be carried out right through the chassis, and even in the body-work. Hence, in the engine, the use of Morse-type chains is rapidly gaining for camshafts and magneto drive, and thus, often enough, the only gears in the engine are those inside the magneto. To quiet this accessory the Bosch firm will in future case in the whole of the gearing and contact breaker mechanisms.

To show what an effect the silent engine has exerted on general design, it may be stated that worm-driven rear axles have become quite general, particularly in cars under 30 horsepower; that chain-driven gear boxes have been tried by several firms (only one firm, Maudslay, has definitely adopted the system for 1912), and that all minor transmission details, such as the universal joints, have been redesigned, with lessened clearance. In the body work all loose joints or creaky places have been eliminated; in addition, rubber buffers are frequently inserted between the body and the frame members.

But, to return to engine design, it is clear now that the unit system of grouping together engine, clutch and gear box has disadvantages in the way of inaccessibility and greater expense of repair, which more than outweighs any mechanical benefits which result from this form of construction. Consequently, fewer makers announce this feature for 1912 than last year. As far as the combination of gearbox and rear axle is concerned, this being, apparently, a system much favored by the American designer, there is not any British car so constructed except the big Sheffield-Simplex car; this is styled the gearless car, in that it is claimed to be always started and driven everywhere on the direct drive. However, to comply with the law, a reverse gear had to be arranged, and at the same time an emergency low gear was provided. These speeds are housed in a forward extension of the rear axle casing.

Malleable iron is largely replacing aluminum for crankcase and gearbox construction, especially for small cars. Here the monobloc, four-cylinder casting is combined with the top half of the crankcase, the lower half being an oil pan made of aluminum or even of sheet steel. However, aluminum is very cheap at present, and therefore its use is not likely to be further diminished. Pressed steel construction has not made the anticipated progress.

Multiple-unit cylinders are increasingly common for fours, about half of the engines under 20 horsepower being of this type. Above this figure pair castings are usual, but for six-cylinder motors the two sets of three is the practice of the best makers. Single-unit cylinders are used by practically no one except Austin; it is curious how this designer, who was responsible for the Wolseley cars for 10 years until he established the Austin Motor Company, resolutely stands by the separate cylinder design.

The argument in favor of a bearing between adjacent throws of the crankshaft is well recognized, and one might safely say that about two-thirds of the best-known engines are thus designed. When a monobloc cylinder casting is used, five bearings are not possible, but three are considered the minimum. Crankshafts with but a bearing at each end are not favored even in the smallest powers. It is somewhat curious that in high-grade, six-cylinder practice there should be a marked difference of opinion. Some makers fit seven bearings; others of equal repute consider four to be ample; but, in any case, the crankshaft bearings and webs of a six are always made much stouter than those of a corresponding four, the actuating motive being not so much that of strength considerations, but the desire to reduce the periodic vibration trouble to the minimum. This complaint has been greatly in evidence since the engines have been quieted down so much, and on some cars the "thrash," or maximum vibration period, has been sufficiently objectionable to call for a radical cure. An effective remedy is provided by the slipping-clutch-flywheel device, fitted on the Rolls-Royce cars and also on the Daimler sixes. This consists of a disc clutch placed on the front end of the crankshaft and having as the driven member a heavy rim, which usually acts as the fan belt pulley. When the critical speed of rotation is reached it is found that the clutch slips somewhat, and this action has the effect of damping down the main vibrations which, if unchecked, would culminate in a very marked tremor. There cannot be any doubt as to the efficiency of this device; a run on a car with the clutch fitted and then with it removed at once demonstrates its successful action.

The subject of engine dimensions calls for some notice. British cars have, in general, smaller engines than American vehicles of similar price and intended for similar work. For instance, the average British four-seater has a 20-horsepower engine—not that there have been many 20's, but that this power is the mean between the two popular types of 15 and 25 horsepower respectively. As all engines are named by their tax rating (which is the S.A.E. formula of $D^2 N \times 0.4$), it will be recognized that 3⅛ inches and 4 inches are the popular sizes for four-cylinder bores. Strokes vary from 1.4 to 1.8 times the bore. The average ratio for 1911 was about 1.5, but for 1912 this is likely to run out at about 1.7. This coming year, too, there are many small fours, with engines of the average dimensions of 70 mm. x 120 mm. rated at 12 horsepower. The bigger fours have each its corresponding six-cylinder model. Surprisingly popular are the sixes, particularly for the covered cars, and this demand shows no signs of abating. The leading makers seem to have no difficulty in obtaining an extra $600 or so for a six-cylinder model. compared with a four-cylinder of approximately the same power.

Consideration of the transmission system indicates clearly that the leather cone clutch is further increasing its preponderance. The disc form is retained by a few makers, but other types, such as the internal expanding shoes or the contracting band, are being replaced by the leather cone. In not a few cases the cone clutch is enclosed, and the rubbing surfaces run in an oil bath. Increased attention has been paid to the flexible coupling bteween clutch and gearbox; this once potent cause of rattle and vibration has now been toned down to the silent level of the other components. A step in the right direction has been made by replacing the "sliding squares" joint by a double Hooke's coupling.

This year shows a general move in favor of the four-speed gearbox; hitherto, three forward speeds have been considered ample for all types, and therefore it is rather a reversal of previous tendency to provide the extra gear on small, medium, and large cars. The influencing factors have been the increased demands which are made upon the small four—that is, the owner of a 15-horsepower four-seater wants to average the same pace be increased—and, secondly, the desire to reduce the engine noise on the indirect gears. With two steps between first and top gear. the maximum engine speed is much less than where only a single intermediate gear is provided, and likewise the rotational speed of the gears themselves is reduced. Invariably, the top gear has the direct drive; the indirect fourth is no longer standard.

A fact in regard to gearsets is that roller bearings have not come into the general use anticipated. Ball bearings are almots universal, and not more than three firms pin their faith to the rollers. In connection with bearings it should be noted that, for engine construction, plain bearings hold almost undisputed play. Ball and roller bearings have proved too noisy, and the advantages gained in other directions were too slight to make them popular. With the effective systems of lubrication now universally employed, plain bearings (white-metal lined in all cases) give perfect satisfaction.

Lubrication systems under two chief types, with many less important variations. Many of the best known engines have pressure feed throughout; others of no less standing show a preference for the troughs-beneath-the-connecting-rods arrangement, where in the supply from the large base sump is pumped into reservoirs beneath each cylinder and thence splashed to all the bearings. In this latter system it is the custom to raise the level of the trough and of the oil therein in accordance with the motion of the throttle lever, so that the supply of lubricant is increased in the same proportion as the load on the engine. It is a curious fact that no decided preference is shown for either the plunger or the rotary-gear type of pump.

A growing practice inclines the engine at an angle of about 8 degrees to 10 degrees, so that the crankshaft may be directly in line with the propeller shaft of the worm-driven axle and the working of the universal joints thus reduced. Of course, if the worm is placed above the worm wheel, the engine remains parallel with the frame, but by far the majority of makers favor the worm-below position. The chief merit of this arrangement lies in the fact that the worm has a copious supply of oil when the car is being started. When running, the lubricant is carried round by the worm wheel, and then there is little difference, as far as frictional loss is concerned, between the two types. It is at the moment of starting, however, that the greatest pressure occurs on the teeth, and, if at this time the surfaces are dry, wearing of the phosphor-bronze worm is inevitable. Worm drive is not universal, but more than half of the leading makes are so fitted. By dint of great care in the planing of the gears, of even more care in the hardening process, and by a final grinding of the teeth or special machines, the makers of bevels are now able to produce gears which are no longer open to the objection of noise. As far as transmission efficiency is concerned, the bevel has a slight advantage over the worm gearing.

A feature which is apparently exclusive to the British trade is the general popularity of the detachable wheel. Quite 75 per cent. of 1912 cars will be so equipped, half a dozen different types of wheels sharing the honors. The wire form of wheel heads the list. This was pioneered by the Rudge-Whitworth firm, but it is also made extensively for supply to the trade by Riley, Goodyear, and others. Some firms, like Humber, make their own detachable wire wheels, but the general custom entails the purchase from the specialist manufacturer. Besides this, the pressed-steel spoke is popular, its superiority over the wire form lying in its improved appearance and greater cleanliness. Where wooden artillery wheels are fitted, these are frequently detachable.

Calendar of Coming Events

Shows

Jan 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17..........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20..........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 20-26..........Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 22-27..........Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dea'ers' Association.
Jan. 22-27..........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Feb. 5-17..........St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17..........Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 14-17..........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24..........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24..........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association
Feb. 19-24..........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 20-24..........Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Week Feb. 22......Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
March 2-9..........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.
March 4-9..........Denver, Col., Auditorium, Annual Show.

Meetings, Etc.

Nov. 20-24..........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 22..........Road Users' Day, under direction of Touring Club of America.
Jan. 18-20..........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Oct. 27-Nov. 3.....Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Nov. 2-4..........Philadelphia Reliability Run, Quaker City Motor Club.
Nov. 3..........Newark, N. J., 125-mile Automobile Endurance Run, *Newark Star*.
Nov. 3-4..........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9..........Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9-10..........Chicago, Team Match, Amateurs vs. Trade Members to Waukesha and Return, Chicago Automobile Club.
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 13..........Harrisburg, Pa., Economy Run, Motor Club of Harrisburg.
Nov. 27..........Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30..........Los Angeles, Cal., Track Races, Motordrome.
Nov. 30..........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25-26..........Los Angeles, Cal., Track Races, Motordrome.

Foreign

Nov. 3-11..........London, Eng., Olympia Show.

The Long-Stroke Motor

TO-DAY everybody is talking the long-stroke motor, but as yet only a very few have definite ideas as to whether there are advantages in it, compared with the square motor of to-day, to warrant the immediate adoption of the long-stroke one. The condition of chaos at present is explained by the different views taken on the question by different factories and also by different engineers. One leading American engineer has been experimenting this Summer with a new long-stroke type and he has announced that he has found it to be less economical of gasoline than a square type and yet give no extra power to compensate for it. Another engineer states that he gets more power out of the long-stroke motor on hill-climbing work over a certain degree of grade, but that under a certain percentage of grade the square motor is superior. One maker, who is an enthusiastic racing man, asserts that he has obtained better speed results out of a long-stroke motor than he ever could dream of obtaining out of the square or nearly square size. So the story of the long-stroke motor goes. Not a single engineer has come anywhere near solving it. They are all, or at least a big percentage of them, trying to solve it, but are yet far from the goal. All of them are learning and education is what we need.

Glancing at the results obtained by not a few of the foreign makers it is interesting to see that the more they investigate the long-stroke problem the better results they are obtaining. One of the best-known motor builders in France—whose ideas have been more widely imitated in America than those of any other foreign builder—has reduced the bore and added to the stroke of every one of his different motor sizes for the coming season. By reducing the bore and adding to the stroke he has increased the horsepower from 6 to over 12, according to model. Not only has the power been increased but the consumption of gasoline has been reduced. This alone is a big factor with the European maker and it is bound to become a factor with many of the American makers. This is particularly the case when it is accompanied by an increase in horsepower. Everybody is looking for an increase in motor efficiency, and if with it can be had a reduced fuel consumption a great victory has been won. The foreign maker has been experimenting with the long-stroke motor for many more years than the American maker, and naturally has solved the problem to a much greater extent. He started off his experiments with racing motors, but during the season just closed what he learned in racing has been applied in modified form to his touring results and the outcome is proving most satisfactory. The racing of a year ago proved that more power can be obtained from a relatively small-powered long-stroke motor than from a very large square type, when certain valve changes are carried out. The same is taking place to-day with touring cars.

Having discovered this in more or less certain terms, at least to suit himself, the foreign builder has for next year gone stronger than ever to long-stroke design. Of the new models that are being exhibited this week at the Olympia in London there is not a solitary one in which the bore is in excess of the stroke, and there is only one in which the bore measures exactly the same as the stroke. In all the others the stroke is much in excess of the bore. A few generalities will suffice to explain this: One of the oldest European builders, and a name which stands highest of all in the automobile engine field, has brought out a new 1912 model of motor with a bore of 70 millimeters and a stroke of 120 millimeters, which is a stroke-bore ratio of 1.71 to 1; in other words the stroke is nearly 75 per cent. greater than the bore. This maker is not a radical, rather has he been looked upon as one of the most conservative of the big builders, and it is a certainty that he has not brought out this new model without having tried it out in every detail. Generally a corps of engineers work on a new model before it is announced and it is never finally accepted until one or two of the directors have given it a thorough tryout; consequently when a new type of these proportions is announced its kinks are generally removed. The act of this maker alone is a big argument for the long-stroke motor. But the story of this one could be repeated with over fifty other concerns. All through it is the longer-stroke type. The proportions of stroke to bore rarely drop below 1.5 to 1; that is, a motor with the stroke over one-half as long again as the bore. Many of the makers have the proportion as high as 1.66 to 1 and a few have reached 1.81 to 1. One or two of the smaller builders have brought out 2 to 1 ratios.

Many arguments are to-day being urged against the long stroke, one being that it makes a longer cylinder casting necessary and so raises the center of gravity of the car. This is true, but it is also true that much can be done to reduce this weight, and it is along this line that much is being done to-day. With the long-stroke motor it would be almost out of the question to try to use valves in the head, and it would be impossible to have an overhead camshaft. As a result the long-stroke motor has started the study of the valve problem. The new location of the valves is but one of the divisions of this question. The shape of the cam has to be altered, the diameter of the valve is a point to be settled, and the manifold problem also presents itself. But if the long-stroke motor presents some troubles in connection with valves it simplifies others. Owing to the longer cylinder castings it permits of a better grouping of the carbureter, the magneto, the water pump and, if necessary, a generator for the electric lighting system. The manifolds can be carried higher up and out of the way of these parts. The same applies to some of the water pipes.

Some have argued against the long-stroke motor on the ground of extra weight, reasoning that because the cylinder castings are longer and the stroke longer, the crankcase must be made deeper and the crankshaft throws longer, so that weight is added along the line. The net result is that makers have been cutting out unnecessary weight in their long-stroke types. The reciprocating parts have been lightened throughout. The tubular connecting rod has been introduced. It gives sufficient strength and is much lighter than the forged type in use at present. The piston has also been cut down in weight. Some makers use steel pistons and the rule of perforation is becoming very general. The crankshaft weight has also been reduced by drilling out the shaft from end to end and cutting down the weight in parts of the shaft where it has not been necessary. In this respect the long-stroke motor is doing much good in making it imperative that makers must improve it in order to make it practical. Necessity has always been the mother of invention, and in case of the long-stroke motor the truth of the adage is being proved once more.

Lubrication was at one time urged as an impossibility in the long-stroke type of motor. In the early days it was considered impossible to oil except with castor oil, and the offensive odor and high price were considered insurmountable obstacles. Well, the long-stroke has come and it is being lubricated, and while castor oil is being used by many, others are demonstrating that it is not necessary and that many of our leading oil makers can produce a grade of oil that will meet all of the requirements. This is simply one more example of necessity compelling invention on the part of the oil people. They stand ready to fill the bill, and when new motor types demanding a special lubricant are brought out they come to the front and supply the lubricant. That maker would be a small quantity who would not build a certain type of motor, solely because he was afraid it could not be lubricated. There are often eccentric constructions, which are wrong from an engineering point of view and also from a manufacturer's viewpoint and which perhaps cannot be oiled, but the long-stroke motor does not come under this classification.

The American maker is wrestling with the long-stroke motor and is going to continue doing so. He will have to. Building a long-stroke motor is not simply adding an inch or so to the height of the cylinder casting, lengthening the connecting rods, making the crankshaft throws longer and deepening the crankcase. Building a long-stroke motor is an engineering problem from the ground up, and the man who will make a success must start out in a broad-minded way to settle the question. He must balance one part to suit the other and cannot pick some pieces out of a four-cylinder motor and put them into a long-stroke one. The conditions under which the two kinds operate are different, the problems in them are different, and each must be approached from its own viewpoint. In a word, the two are entirely different in the many problems that enter into them.

Schimpf Succeeds Butler

WILLIAM SCHIMPF, president of the Long Island Club and a member of the A. A. A. Contest Board for the past year, has been appointed by President Robert P. Hooper to fill the vacancy caused by the death of the late Samuel M. Butler. The appointment followed a conference involving President Hooper, of the A. A. A., and President H. E. Coffin, of the Manufacturers' Contest Association, which co-operates with the owners' organization in the conduct of automobile competitions. Mr. Schimpf is the head of one of the largest automobile clubs in this country, and is naturally greatly interested in competitions, his service on the board having given him a complete understanding of the needs of the position to which he has been appointed.

Last Rites for Samuel M. Butler

Samuel M. Butler's funeral was held at his late home in Brooklyn on Sunday in the presence of a considerable number of his close personal and business associates. Floral tributes were numerous and beautiful. The exercises were simple. Interment was at Greenwood.

Despite the fact that the funeral was private there were many men prominent in automobiling circles present, including all his associates in the A. A. A. and many high lights of the trade newspaper world.

There was a splendid array of floral exhibits which had come from personal friends, including handsome designs from the Automobile Club of America, the Manufacturers' Contest Association, the Chicago Motor Club and his associates at the National headquarters in New York City.

Soft Pedal on Show News

LEST the publication of show arrangements check retail business at this season, the Automobile Board of Trade and the National Association of Automobile Manufacturers have put down the soft pedal on announcements for the time being.

Business is reported fairly good along the row but the tendency to slow up in anticipation of the shows is felt in some quarters.

As a matter of fact, the developments in the show situation during the week have not been important and simply represent normal progress in preparation for the two big exhibitions to be held in New York.

Composition Proposed for Streator

Composition of the unsecured debts of the Streator Motor Car Company, together with those of Paul R. Chubbuck and John C. Barlow has been suggested by a committee of the creditors of the embarrassed company. The plan brought forward is to release the company from liability for its former debts and the acceptance on the part of the creditors of bonds issued by the People's Trust and Savings Bank as trustee for the debtors. A trust deed conveying to the bank the assets of the Barlow and Chubbuck is a condition precedent.

The bonds will be signed by Barlow and Chubbuck and will be issued to the creditors through the bank if the proposal is accepted. Except for some trivial claims, the bonds are conditioned to mature as follows: 10 per cent. in 1 year from Sept. 23, 15 per cent. in 2 years, 20 per cent. in 3 years, 25 per cent. in 4 years, and 30 per cent. in 5 years, together with interest on the unpaid balances at 6 per cent.

Case, No. 3, Hansen, driver, finished four days with a clean score

Many Clean Scores in Chicago Run

LOUISVILLE, KY., Oct. 29—The fifth annual reliability run of the Chicago Motor Club, which started from Chicago Friday morning with seventeen contestants and five official cars, has completed two legs of the 8-day tour that has been mapped out by the Chicago organization. Illinois, Indiana and part of Kentucky have been traversed and as yet nothing has been accomplished toward deciding the winners. Only one of the seventeen cars has been penalized and that only for trivial troubles brought about largely by the inexperience of the driver —an amateur who put in his big National roadster for the fun of it. Certainly sixteen cars clean after 404 miles of going is a most remarkable showing, a showing such as never before has been made in a Chicago reliability.

The tour got an auspicious start from Chicago Friday morning, with only one car scratched, that a Lion that was pulled out because the change of date did not suit the entrants. This left nine running in the touring car section and eight in the roadster division, striving for four prizes—the touring car cup, the Van Sicklen roadster trophy, the Chicago Motor Club team trophy and the fuel economy prize offered, as usual, by the Standard Oil Company.

The first day's run was from Chicago to Indianapolis over a route that differed from the conventional in that it followed a new trail that led past Hazelden farm, the home of George Ade, the novelist, who had invited the motorists to make his place the noon control. It was 94 miles to this place and it was easily negotiated even though the contestants had to make a 5-mile detour just out of Crown Point because a new stone road that was included in the original route had not been opened to traffic. The stop at Ade's long will be remembered by the contestants. The novelist gave the motorists the run of the farm and the noonday meal was served by the Daughters of Ruth, who are raising a fund to build a church. The novelist also had a "life saving" station on the second floor which was greatly appreciated by the motorists after the cold drive. He also provided them with souvenir postal cards, already stamped. Of course each man wrote one and Ade agreed to mail them. This gave him an opportunity to crack a merry joke. In writing for the Indianapolis *Star* of the visit of the Chicagoans, Ade dryly added: "I have read all the souvenir postal cards left here to be mailed, and I find that the visitors were wildly enthusiastic about the dinner."

Velie, No. 104, Stickney at the wheel, unpenalized at half-way point

It was no trick at all to drive from Ade's to Indianapolis, although the distance was 130 miles, and everyone got in on time and with plenty to spare. The work of the technical committee was easy, for there only was one card to consider, that of Paul Strauss, driver of the National, who had drawn 3 points for carbureter adjustments at the start, undoubtedly caused by the chill weather. All others were clean and no one had any complaints to make.

In the evening the Chicagoans were the guests of the newly formed Hoosier Motor Club and the evening was devoted to speeches by men prominent in the motor world.

Indianapolis to Louisville

The run from Indianapolis to Louisville yesterday only was 178.5 miles, but it proved an eye-opener to the Chicagoans, who had not realized that right at their doors is a touring territory that cannot be beaten anywhere in the country. Certainly the Berkshires can offer nothing better in the way of scenery and the roads through southern Indiana and that portion of Kentucky running into Louisville cannot be improved upon much. The Chicagoans struck the beautiful scenery about 20 miles from the noon control, Bedford. Just outside of Medora, 83 miles from Indianapolis, was encountered a most remarkable hill which would have been a serious proposition had it rained. It is about 1-2 mile in length and the average grade is about 16 per cent. It is a veritable corkscrew, with little short turns that wind not abruptly but continuously to the top. There must be not fewer than ten turns on the way up—in fact, it is like climbing a chimney. The road bed itself is excellent and the road winds through a thick wood that but adds to the beauty of the climb.

Leaving Bedford at noon, the tourists found they had but just tapped the southern beauty vein. The magnificent roads continued and the tour had hardly left Bedford before there was encountered a most remarkable freak of nature—a hogsback road that ran for about a mile on the top of a sharp ridge between two beautiful valleys. One could look either way and drink in the scenery. On one side was a winding river and on the other heavy woods. The road itself took up the full width of the ridge and no driver dared take his eye off the highway to peek at the scenery lest he plunge into a chasm.

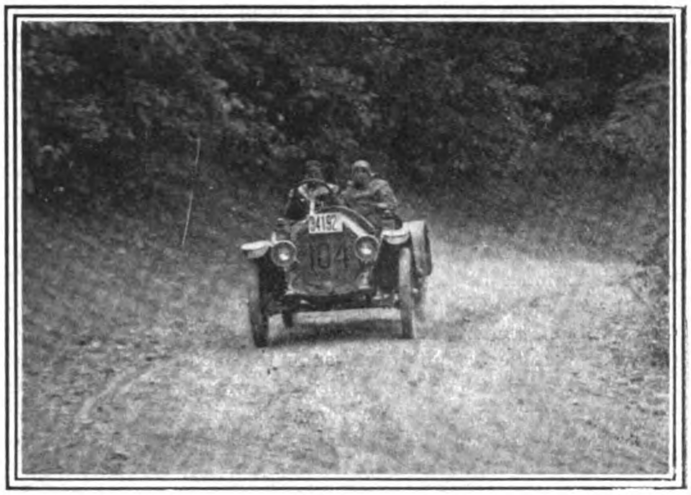
Hardly had they passed this beautiful stretch than the winding road brought them face to face with a hill that made Algonquin pale into insignificance, a 20 per cent. grade that rose abruptly from the valley road. Luckily it was straight and the road good, else there might have been trouble. No one, however, experienced any trouble getting up.

This fine road continued to within about 30 miles of Louisville. At one place it followed an interurban trolley, being first on one side and then on the other. Someone counted and declared afterwards that this trolley line was crossed no fewer than thirty times before the trail straightened out and swung into Louisville.

Reaching here yesterday afternoon, the tourists looked back over the day and marveled at the wonders. They declared themselves surprised at the fine roads of southern Indiana. It was surprising, too, because there were so few motor cars encountered on the road, while the inhabitants themselves did not seem to be overburdened with wealth. Yet there were found well-built roads, wide and rutless, with stone bridges at some places, and, best of all, these roads have every appearance of being maintained. The towns themselves seemed prosperous, but the day's journey failed to show any great motoring strength in this section. The people themselves seemed friendly to motoring and in each town the inhabitants gave the tourists the glad hand.

This trip of the Chicagoans seems destined to open the eyes of the western motoring world to the beauties that lie at their doors. It is hard to realize that within a day's journey of Chicago there is a territory that is so rich in good roads and fine scenery as this and it is predicted that in another year the itinerary that is being followed by the Chicago Motor Club will be the scenic tour of the middle west.

The run from Indianapolis here failed to disturb any of the perfect score section. Strauss in the National drew 27 more points—14 for changing spark plugs and 13 for being late. The Case bent part of its steering connection trying to follow the trail over a stretch of railroad ties, but this was whitewashed by the technical committee because the checker had failed to carry out the instructions of the referee. When the stretch over the tracks was reached the referee saw the confetti spread along it, but he realized this was asking too much of the cars and he found a detour through a back yard and ordered the confetti strewn that way. The old paper was not picked up and the leading cars took the railroad route, the Case meeting with its mishap in consequence. The referee held that the accident had been brought about by the failure of one of the officials to carry out orders and no penalty was imposed.



Midland, one of the official cars, did excellent work on Medora hill

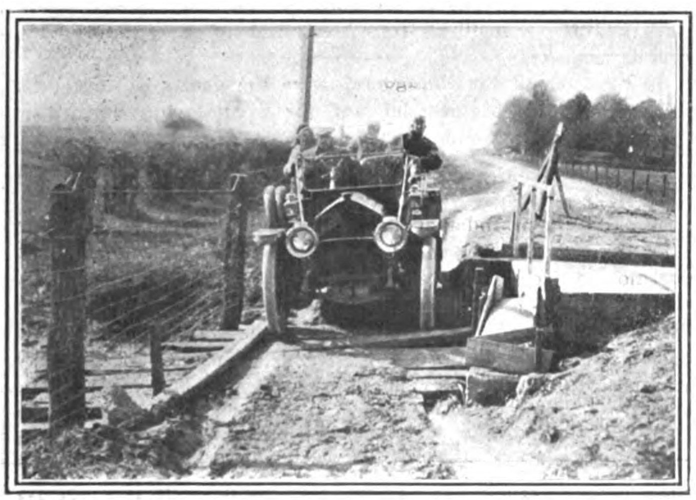
Resting up to-day, the Chicagoans this afternoon were the guests of the Louisville Automobile Club, which kept open house and devoted the entire afternoon to its guests.

From here the tour goes to Cincinnati to-morrow, Columbus Tuesday, Detroit Wednesday, Grand Rapids Thursday and home Friday.

Louisville to Cincinnati

CINCINNATI, O., Oct. 30—The contestants in the Chicago run finished a double century from Louisville this afternoon, and after the count was made to-night it was discovered that the remarkable record of the contest had been retained to a certain extent. Two drew black marks to-day, making three in all that have been demerited since the start of the run from Chicago last Friday. That fourteen cars could go 592 miles with perfect scores is a record seldom equaled in reliability contests. The two to lose their perfect scores to-day were No. 107 Grout in the roadster division and No. 9 Staver-Chicago, in the touring car class.

The Grout met with its mishap this morning. Coming down a hill 40 miles out of Louisville it skidded and before Halbert could



The National press car negotiating a tender bridge the first day

Some of the roads traversed the first day were miniature lakes secure control of it it had run off a bridge, ripped off a rear tire and broken a spring. The occupants had a close call. Halbert patched up the broken spring, incurring 40 points thereby, to which was added 8 points for being late. The Grout will get more to-morrow morning, for it is the intention to replace the broken spring. Monckmeier's Staver was given 9 points, 7 of which were for adjusting a ball retainer and the other two for being late.

But one of the other perfect scores is threatened, No. 101, Moline, which is being driven by J. Boone; going through Shelbyville, at 12 miles an hour, a negro driving a rig turned in front of Boone, who found it impossible to avoid a bump, the result being a bent fender.

The trip to-day again led through the picturesque portion of Kentucky and over good roads, too. It was sprinkling when the tour pulled out of Louisville for a 100-mile run, but the rain was a gentle one and did not harm anyone. The roads being of stone construction, it was easy to keep going and no one worried over the weather. At Frankfort, the capital of Kentucky, the tourists were duly impressed with the high bluffs and the winding roads, but they were lost in admiration at Shakertown, when they swung down a big mountain into the Kentucky River valley, the deep gorges and the rocky formations being of a grandeur to which the Chicagoans were not accustomed. Lexington, the noon control, was reached after a trip of 116 miles and in the afternoon the tour was resumed over roads that were as winding as a corkscrew. One can get an idea of the twists by learning that the railroad was crossed thirty-seven times during the afternoon between Lexington and Covington, Ky.

The Chicagoans also got their first toll-gate experience this afternoon, being forced to pay tribute five different times. They found, too, that the roads at this end of the day's run are not so good as in the morning.

This evening the visitors were given a royal reception by the Cincinnati Automobile Club, which put on a big stag and smoker.

From Cincinnati to Columbus

COLUMBUS, O., Oct. 31—To-day's run of the Chicago Motor Club's Reliability, the fourth of the tour, was prolific of incidents that happily resulted in no one being hurt, but which decimated the perfect score field by three and left eleven surviving for the honors of this classic. The Halladay and the Oldsmobile Autocrat in the touring car division, and No. 104, Velie, in the roadster class, were demerited, while Halbert, in the Grout, had to replace the spring he broke yesterday.

The Halladay incurred 19 points, 3 of which were for cleaning the gasoline line and 16 for work on a fender iron that broke. The Oldsmobile started out with a broken gasoline line, small in itself but which grew like a rolling snowball until to-night there are charged against the Autocrat 455 points, while still more await it when the technical examination is made Saturday. To start out with, the break in the line compelled Winters to take on gasoline three times, for which he was fined 9 points. Then at the noon control at Washington Court House, he was obliged to lay up and take off the body to mend the leak. That cost 208 points. This done, the Oldsmobile started for Cincinnati, but a mile out of town in trying to pass a horse-drawn vehicle it skidded, hit the team and just escaped plunging down a 20-foot bank. It required nearly three hours to get out of this fix, the farmers being called on to help with horses. This made the Oldsmobile late to-night and the time penalty was 238 points.

The penalization of the Velie was slight, only 1 point. Davies fixing the muffler cut-out rod, which had become disconnected. The Grout got 340 points to-day, 246 being used up in putting in the new spring, two for a clutch adjustment and 92 for being late at the noon control. The car was on time to-night.

Another victim to-day was the Abbott-Detroit 44, driven by Robbins, which broke a leaf in the front spring while yet in the limits of Cincinnati. Robbins did not have to touch it, however, and it looks as if he would be able to go through the tour with it, which would not cost him his perfect road score. The penalization of the Velie and the Halladay leaves the Moline the only make clean for the team trophy, for which it has a double chance, for this cup is decided by the two best aggregate scores. The Staver, the fourth contender, was penalized yesterday, when Monckmeier caught it.

The run to-day was 178 miles from Cincinnati to Columbus, with the noon control at Washington Court House, 98 miles. The morning route ran through Dayton and the afternoon touched Chillicothe. When the tourists left this morning the skies were cloudy and the roads muddy following last night's rains, which made the going necessarily slow.

The run to-morrow will be a hard one, Detroit being the destination. The roads between Toledo and Detroit are reported bad, and it may be necessary to make a detour to get past some of the impossible stretches. The table of penalties up to date follows:

No.	Car	Driver	1st day	2nd day	3rd day	4th day	Total
1	Moline	N. Van Dervoort	0	0	0	0	0
2	Moline	Salisbury	0	0	0	0	0
3	Case	Hansen	0	0	0	0	0
5	Halladay	Daubner	0	0	0	19	19
6	Halladay	Davies	0	0	0	0	0
7	Oldsmobile	Winters	0	0	0	455	455
8	Abbott-Detroit	Robbins	0	0	0	0	0
9	Staver-Chicago	Monckmeier	0	0	9	0	9
10	Staver-Chicago	Knudsen	0	0	0	0	0
		Roadsters					
100	Moline	Wicke	0	0	0	0	0
101	Moline	Boone	0	0	0	0	0
102	Oakland	Bauer	0	0	0	0	0
103	Velie	Gibbons	0	0	0	0	0
104	Velie	Stickney	0	0	0	1	1
105	Bergdoll	Monsen	0	0	0	0	0

Group of members of the Society of Automobile Engineers en route to England on the Mauretania

S. A. E. Delegates Sail for England

THEY'RE off for Olympia! At 9 o'clock Wednesday morning a party consisting of fifty-five persons, representing the Society of Automobile Engineers, sailed for England on the steamship Mauretania on the first official visit of that organization to foreign shores.

The S. A. E. was invited to hold a joint convention with the Incorporated Institution of Automobile Engineers of England and the present trip is the outcome.

The following list is a roster of the party: B. B. Bachman, Ardmore, Pa.; Mr. and Mrs. Walter C. Baker, Cleveland, Ohio; Mr. and Mrs. J. S. Bretz, New York; Mr. and Mrs. Albert Champion, Flint, Mich.; Mr. and Mrs. H. D. Church, Detroit, Mich.; Mrs. D. H. Church, Cambridge, Mass.; Coker F. Clarkson, New York; Mr. and Mrs. Howard E. Coffin, Detroit, Mich.; John A. Crowley, New York; Arthur B. Cumner, Philadelphia, Pa.; E. A. DeWaters, Flint, Mich.; H. F. Donaldson, New York; F. S. Duesenberg, Des Moines, Iowa; B. G. Ellis, Boston, Mass.; John W. Foster, Amesbury, Mass.; C. H. Foster, Cleveland, Ohio; H. Jay Hayes, Detroit, Mich.; Robert T. Hendrickson, Fremont, Ohio; J. B. Hull, Cleveland, Ohio; William Kelly, Detroit, Mich.; George W. Kerr, Chicopee Falls, Mass.; Hugh Kerr-Thomas, Buffalo, N. Y.; Charles B. King, Detroit, Mich.; Mr. and Mrs. W. P. King, Cleveland, Ohio; Mr. and Mrs. Robert McA. Lloyd, Long Island City, N. Y.; D. G. McDiarmid, Chicago, Ill.; Mr. and Mrs. Alden L. McMurtry, New York; Carl J. Metzger, Ottawa, Ill.; William E. Metzger, Detroit, Mich.; Mr. and Mrs. Charles J. Moore, Detroit, Mich.; Bert Morley, Detroit, Mich.; C. S. Mott, Flint, Mich.; Ralph H. Rosenberg, Columbus, Ohio; A. J. Slade, New York; C. O. Snyder, Chillicothe, Ohio; Paul L. Snutsel, New York; H. C. Stutz, Indianapolis, Ind.; H. T. Thomas, Lansing, Mich.; T. R. Thomas, Racine, Wis.; G. R. Wadsworth, Cleveland, Ohio; W. G. Wall, Indianapolis, Ind.; Mr. and Mrs. G. A. Wahlgreen, Denver, Col.; Mr. and Mrs. Henry C. Wilson, New York; John G. Wood, Indianapolis, Ind.; Mr. and Mrs. S. G. Wingquist, Gothenburg, Sweden.

The following members will join the party in Europe: A. Ludlow Clayden, London; C. E. Davis, Muncie, Ind.; Marcel DeJarney, London; Charles L. Lawrence, Paris; Fritz Loeffler, Walhof, Mannheim, Germany; Louis C. Marburg, New York; A. J. Moulton, New York; A. J. Myers, Paris; Rene M. Petard, Paris; Adolph Rosner, Bridgeport, Conn.; Alfred J. White, Coventry, England; David R. Wilson, Cleveland, Ohio; Arthur Ziltener, Wessen, St. Gallen, Switzerland.

Olympia Show Offers Promising Outlook

LONDON, Oct. 21—In less than a fortnight the doors of the big Olympia building in the West End will be opened to disclose the tenth International Exhibition of Automobiles and Accessories promoted by the all-powerful trade organization, the Society of Motor Manufacturers and Traders. On Nov. 3 the show will be opened without ceremony, and it will run on till Nov. 10.

Never before has there been such a crowded assembly; some 310 exhibitors share the space, and fifty more, unable to find an unoccupied corner, are housed in neighboring showrooms.

It is rather a notable fact that nearly half of the number of American car agents are outside the show; this does not indicate that they were last with their applications, but rather that they do not care to sign the bond and guarantee clauses in respect of other exhibitions and trade maintenance generally.

To prevent the crush which has always occurred at previous exhibitions, the admission price is doubled on two days and doubled again on Society Day, Nov. 7. Another advantage from the visitor's point of view is the new rule forbidding the stand attendants to smoke while on duty. A further prohibition relates to mechanically operated working models; these usually attract such crowds that neighboring stand-holders find their business interfered with. Models there will be in plenty, but small boys will provide the necessary horsepower.

As regards the general outlook, interest is likely to center on the new small four-cylinder cars (admittedly a competitor of the American light car, but hardly a worthy foeman), on the medium-powered six-cylinder vehicles, and on the covered body exhibits. As far as the accessory section is concerned, electric lighting dynamo equipments are the special feature this year.

French Clubs Resume Race Control

ON October 18 the committee on sports of the Automobile Club de France convened with René de Knyff in the chair to decide whether the club should organize any automobile contests in 1912. The comments of the French automobile press with regard to the probable decisions of the committee—and no doubt intended to influence these decisions—throw light on the situation and a reflex light on the export interests of American manufacturers.

In an article in *L'Auto* on the day of the meeting, Charles Faroux, the editor of *La Vie Automobile*, wrote as follows:

"It is infinitely probable that the organization of one or perhaps even two contests will be decided. Public opinion has made itself plain in this direction. The purchaser wants one or two races. Better acquaintance with the progress accomplished by our rivals has sufficed to show that races are desirable, and a glance at our export statistics for the past two years demonstrates their necessity. From the purely utilitarian viewpoint a trial for light vehicles commends itself on lines similar to those inaugurated with so much success by *L'Auto* in the Boulogne races. As a matter of spectacular sport and with a view to striking the susceptibilities of the philistine masses, a race for large vehicles seems equally necessary.

"The regulations for the light vehicle race will be determined in due time and should be considered with great care. As regards the rules for the race for heavy cars, the report that absolute liberty will be adopted seems to be confirmed. It is well known what the writer thinks of this policy after having thought a great deal on the subject lately: It represents the worst possible conclusion whether looked upon from a technical or a national viewpoint. All the races which have been run for several years in France or abroad have shown with eloquent unanimity that the builders never cared to perfect any points in the design excepting those affected by the regulations. When there was a weight limit the metallurgical end of the builder's art made progress, and that only. Gains in motor or transmission efficiency date from the appearance of regulations bearing upon the bore or the fuel economy. Recently, at Boulogne, where the writer had neglected the question of weights a trifle, the vehicles were at once found to be far too heavy. They were ten years behind in this respect, at the same time that they exhibited great progress in motors and transmissions. At aviation contests this experience is repeated.

"Many say: 'Let all race who will, and we shall soon see who is the best.' But this is a layman's argument. It represents the negation of all method. They say it represents a formula which the public can understand. True, but mechanical progress is not concerned with the public; it is accomplished apart from the public choice. In fact, has the public ever adopted a demonstrated improvement at once, whether the question was of magnetos or of ball bearings?

"Then there is another side to the matter. On a basis of absolute liberty all that is required for winning is time and money, and these requirements can be met abroad as well as in France. To win under studied rules, on the other hand, requires a highly organized experimental and engineering department, superior service in 'tuning up' and a substantial experience in racing and technical matters; and these are all things in which we excel. This is no time for fanciful decisions. Whether one likes it or not, a race bears certain relations to the industrial development."

As anticipated in the article quoted above, the decision taken by the Sport Committee of the Automobile Club de France at the meeting referred to was in favor of resuming race control and the resolutions adopted provided for one free-for-all race to be known as the Grand Prix of the A. C. F., and in addition for a race designated as Coupe du Journal *L'Auto* for cars with a cylinder volume limited to 3 litres (183.066 cubic inches), and in other respects similar to the Grand Prix de Boulogne race which was so successfully arranged by *L'Auto* during the past year.

It is provided that the two races shall both extend over two successive days and that a distance of about 1,000 kilometers shall be covered by each of the contestants each day, making the total distance about 2,000 kilometers; change of drivers will be permitted.

Neither of the two events is to take place before June 23, 1912, but otherwise the dates are still to be decided. Both are to be run at the same time, however, and it is considered probable that the Dieppe course will be selected as the battle ground. The races will both be international, and the Sport Committee has provided a prize of 20,000 francs for the winner of the Grand Prix, this prize to be awarded to the builder of the fastest car, irrespective of the nationality of the constructor or the classification of the vehicle.

L'Auto mentions as certain competitors for the Grand Prix the Lorraine-Dietrich, the Darracq, the Cottin-Desgouttes, the Rolland-Pilain, the Fiat, the Mercedes, the Benz and four American cars, the Marmon, the Lozier, the Stoddard-Dayton and the National. The information with regard to the intentions of the manufacturers of these cars is said to be authorized. As possible participants are mentioned the Clement-Bayard, Mors, Opel (German) Itala, S. P. A. and Austrian Daimler.

For the Coupe du Journal *L'Auto*, the following are referred to as most likely to take part: Delage, Lion-Peugeot, Sizaire-Naudin, Gregoire, Hispano-Suiza, Côte (two-cycle engine), Koechlin (two-cycle engine), Sunbeam, Vauxhall, Calthorpe, Arvol-Johnston, Argyll, Excelsior, Fif, Mathis, Laurin-Klement and Puch.

Fords in French Glidden

By conference between a number of French manufacturers and the directors of the journal *L'Auto* a new set of regulations has been adopted for the Tour de France, to take place March 1 to 16, 1912. The event will be a test of endurance and regularity for stock cars of the light vehicle and the voiturette classes. As light vehicle any car may be entered which is catalogued for 1912 at a price for the chassis, without tires, not exceeding 8,000 francs, and as voiturette any car whose 1912 catalogue price is not higher than 4,000 francs, including the cost of body as well as tires.

The entry lists were opened Friday, October 21, at the offices of *L'Auto*, in Paris, and will remain open until January 31, 1912, midnight. Entries must be accompanied by the entry fee which is scheduled as follows: For one light vehicle 500 francs, for two light vehicles of the same make 900 francs, for three light vehicles of the same make 1,200 francs; for one voiturette 250 francs, for two voiturettes, 450 francs and for three voiturettes 600 francs. Every participant must produce before being allowed to start, an insurance policy proving that the life of the driver and the risk to third parties are covered in the sum of 100,000 francs in case of accident, and a duplicate of this policy must be deposited in advance at the office of *L'Auto*.

Among the very first entries for this contest were three Ford cars (American), one Delage car and three Barre cars, all in the light vehicle class.

Late Trade and General News

PITTSBURGH, PA., Oct. 31—Decision of the suit entered by the Republic Rubber Company, of Youngstown, O., against Morgan and Wright, with regard to alleged infringement of patents granted to the plaintiff concern for staggard tread tires, is expected next week. The patent in question was issued to T. J. Mell, of the Republic company, in 1907, and it is alleged that the Morgan and Wright patent was not filed until January, 1910.

The suit is in the United States Circuit Court and was heard by Judge Hazel. The complaint asks for an injunction against the defendant company prohibiting it from manufacturing its knobby tread tires and for damages for infringement. Several tire companies not affected by the suit have been manufacturing non-skid tires and it is stated that after the completion of the matter in hand the Republic company contemplates more litigation.

Christy & Christy, of Pittsburgh, represented the complainants in this action and Ernest Hopkinson, Edward W. Vaill and Antonio Knauth, of New York, appeared for Morgan and Wright.

Date Set for Indianapolis Race

INDIANAPOLIS, IND., Oct. 31—At a meeting of the Speedway management to-day it was decided that the second annual 500-mile International Sweepstakes race will be held on next Memorial Day, May 30, at the Speedway. The prizes for the event will amount to $50,000, to be divided into twelve awards as follows:

First, $20,000; second, $10,000; third, $5,000; fourth, $3,000; fifth, $2,500; sixth, $2,000; seventh, $1,500; eighth, $1,400; ninth, $1,300; tenth, $1,200; eleventh, $1,100; twelfth, $1,000.

The race will be for cars with 600 cubic inches piston displacement or less and a minimum weight of 2,000 pounds, making it a class E event. The speed requirement will be 75 miles an hour for one full lap of the 2 1-2-mile track. The field of starters will be limited to the thirty fastest cars to be selected in competitive trial if more than thirty entries are registered at the time of the race. In case of rain the A. A. A. has given permission for the race to be run on the following Saturday.

Oklahoma to Vote on Bonds

OKLAHOMA CITY, OKLA., Oct. 30—A bond issue of $1,250,000 for good roads in Oklahoma county will be voted on at a special election which has been called by the county commissioners. This election will be held November 23 and is called in response to a petition presented to the commissioners.

The petition contained 13,000 names and was the longest petition ever submitted in the history of Oklahoma county for any purpose. Oklahoma City is the county seat and pays more taxes than the rest of the county outside of the corporate limits but the petition was signed by town people with as much promptness as it was by farmers.

T. C. A. Party Starts from Atlanta

ATLANTA, GA., Oct. 30—Starting from this city to-day the pathfinding party of the Touring Club of America commenced its journey to Richmond at 8 o'clock. The trip will cover Greensboro, Ga., Augusta, Columbia, S. C., Camden, Cheraw, Pinehurst, N. C., Raleigh, Henderson, Emporia, Va., and Richmond as night and noon stops, a distance of 695.3 miles. The party will arrive in Richmond November 3.

Those who compose the party are: W. J. Dabney, Richmond. Henry MacNair, New York; H. B. Varner, Lexington, N. C.; Lee A. Folger, Richmond; F. H. Elliott, New York; D. D. Armstrong, Atlanta, and W. D. Gordon, Richmond. All are prominent in the movement for good roads from a national aspect. Through the various States to be traversed the party will be escorted by highway commissioners and others who are making a close study of road construction and maintenance. A Chalmers six-cylinder car is being used as pilot in charge of Mr. MacNair, editor of the *Blue Book.*

Ready for Dash Across Desert

LOS ANGELES, Oct. 30—Sixteen tuned to the minute and desert-equipped motor cars will start on a 550-mile battle with the mountains and sand at 10.45 Saturday night. The start will be from the center of the Los Angeles business district and for 2 days and 1 night these machines and their crews will be covering the distance across the great American desert between Los Angeles and Phoenix in as fast time as can be made by a motor-propelled vehicle. Following is a list of the entrants:

Car.	Piston Dis.	Driver.
1—Maxwell	229	Clarence Smith
2—Pope-Hartford	299.4	W. D. Tremaine
3—Franklin	301.5	Ralph Hamlin
4—Stoddard-Dayton	550	E. Roger Stearns
5—Cadillac	286	W. W. Bramlette
6—E. M. F.	226.2	W. La Casse
7—Flanders	154.8	Geo. Soules
8—Cole	286	John Jenkins
9—Mercer	286	H. Hanshue
10—Case	236	W. F. Brong
11—National	448	Harvey Herrick
12—Buick	318	L. Nikrent
13—Fiat	618	Teddy Tetzlaff
14—Midland	318	F. Siefert
15—Lexington	280.6	C. Bigelow
16—Buick	318	J. Ferguson

Tire Makers Busy with Orders

AKRON, O., Oct. 30—The state of the automobile industry and the magnitude of plans being made for next year's business by automobile manufacturers, is reflected in the activity now apparent among Akron tire factories, all of which report that they are much busier now than is usual at this time of year. Akron tire makers are prepared for unprecedented production this winter, based on orders already booked or assured, due to the unusual campaigns mapped out by the manufacturers of medium priced cars.

The steadiness of the crude rubber market at a satisfactorily low rate has helped to ease conditions in the tire business. Since the breaking of the Brazilian and British corner in South American rubber, there have been few marked fluctuations in crude rubber quotations, and local manufacturers predict that for several years at least there can be no such soaring of rubber prices as were recorded a year and two years ago.

Six New Members of the A. B. of T.

The following new members have been elected to the Automobile Board of Trade: Warren Motor Car Company; James Cunningham Son and Company; Garford Company; Reliance Motor Truck Company; Rapid Motor Vehicle Company and the Marquette Motor Company. The latter organization is practically a consolidation of the Welch-Detroit and the Rainier.

NEWS of the WEEK CONDENSED

CHICAGO, ILL.—Many dealers and branch house managers attended a convention held at the plant of the Velie Motor Vehicle Company, Moline, Ill., October 20 and 21. Meetings were held at the assembly hall and talks on various subjects were given by men of the different departments: Chief Engineer C. B. Rose, General Manager Major L. M. Fuller, Sales Manager George H. Floyd and his assistant, Charles P. Hatter. A banquet was given on Friday evening in the Marble Hall at the Manufacturers' Hotel. Major L. M. Fuller acted as toastmaster. Immediately afterward the visitors were escorted in pleasure and commercial cars to the American Theatre, at Davenport, Ia.

AKRON, O.—The Jones Auto Company, of 53-55 South High street, has taken the agency for the 1912 Hudson.

WASHINGTON, D. C.—Earl & Allen, who are agents for the Hupp-Yeats electric, have secured the R. C. H. car.

WASHINGTON, D. C.—The Overland-Washington Motor Company has been appointed agent for the Garford in this city and the surrounding territory.

WASHINGTON, D. C.—M. T. Pollock, agent for the Oldsmobile, is making extensive improvements in his salesroom at 1018 Connecticut avenue, N. W.

BOSTON, MASS.—George H. Bammann, well known in Boston motor circles, has accepted a position with the Bi-Motor Equipment Company as a salesman.

WASHINGTON, D. C.—The Waverly Electric agency has been placed with the Luttrell Company, Dupont Circle and Connecticut avenue. This company also handles the Packard.

PHILADELPHIA.—A local branch of the Polack Tyre Company, manufacturer of solid rubber tires for commercial vehicles, has been established at No. 408 North Randolph street, with M. Smolens as manager.

PHILADELPHIA.—An eastern distributing agency for the Cutting car, of Jackson, Mich., has been established at No. 1431 Spring Garden street. Benjamin H. Kirkbride is manager for Pennsylvania, New Jersey and Delaware.

INDIANAPOLIS, IND.—The Rapid Motor Transit Company, of this city, began its motor bus service on November 1 with seven gasoline motor busses built by the White Company, of Cleveland, O. The cars are lighted and heated by electricity.

INDIANAPOLIS, IND.—R. L. Bartol has resigned as manager of the Ford sales branch in this city and has been succeeded by Dayton E. Keith, formerly with the Ford sales branch in Chicago. Mr. Bartol will conduct the Ford agency in Anderson, Ind.

SYRACUSE, N. Y.—The H. H. Franklin Manufacturing Company is now taking on mechanics to meet needs occasioned by increased production. Machine departments are working evenings, and several hundred skilled machinists will be put on during the coming weeks, it is reported.

TWO RIVERS, WIS.—Officials of one of the big aluminum manufacturing companies here deny reports that prices of raw and finished aluminum are slated for a decided drop. Although competition is growing stronger, the demand is increasing more than proportionately and no decline is looked for.

PHILADELPHIA.—Edwin H. Lewis, well known in local automobile circles and a prominent member of the Quaker City Motor Club, has become associated with the factory sales department of the Louis J. Bergdoll Motor Company, acting as traveling representative of the company.

COLUMBUS, O.—According to State registrar of automobiles Shearer Ohio is second among the States of the Union in automobile registration. In the report of licenses issued by the various States up to October 1, New York leads with over 80,000, Ohio is second with 45,421, and Pennsylvania is third with 43,074.

MILWAUKEE, WIS.—The Secretary of State of Wisconsin has announced that applications for 1912 registrations and licenses will not be received before December 15, instead of December 1, as previously stated. Annual registration went into force on September 1, 1911, in Wisconsin, and all cars will have to be registered by January 1.

BEVERLY, MASS.—The makers of the Cameron car at Beverly are arranging to enlarge their plant upon the receipt of more capital and offers have been made to them by another concern to consolidate. The company has just received word from abroad that in the closing race meet at Brooklands, Eng., the 70 miles an hour handicap was won by one of their 20-horsepower cars from a field of 15 starters. It created much surprise, for the Cameron was not looked upon as having any chance to capture the event.

NEW YORK CITY—In the recent automobile exhibition at Berlin 82 manufacturers of automobiles exhibited. Of these 71, or 86.7 per cent., exhibited cars equipped with Bosch magnetos.

BALTIMORE, MD.—The Lambert Automobile Company is now located in its spacious new quarters at Maryland and Mount Royal avenues. The firm handles the Maxwell, National and Hudson cars.

PITTSBURG, PA.—The Pittsburg branch of the Franklin Automobile Company signed up two sub-dealers in this territory during the week: The Coraopolis Garage Company, of Coraopolis, Pa., and S. F. Carpenter, of Carbondale, Pa.

AKRON, O.—The B. F. Goodrich Company is opening three new Southern tire depots—at Nashville, Tenn., in charge of M. D. McKenzie; at Charleston, N. C., in charge of A. J. Kelley, and at Birmingham, Ala., in charge of L. F. Joliat.

TOLEDO, O.—The Rambler Sales Company has accepted the agency for the Detroit Electric in Toledo territory. This car was formerly handled by the Toledo Auto & Garage Company, which will now devote its entire time and attention to the housing of cars.

SYRACUSE, N. Y.—A. D. McLachlan has severed his connection with the Royal Tourist Motor Car Company, of Cleveland, O., and accepted the position of general sales manager for the Sanford-Herbert Company of this city, who manufacture a light delivery wagon.

TOLEDO, O.—The Gamble Motor Car Company, of Toledo, has taken over the agency of the Ohio Electric. An extended demand for this car is reported, several sales being closed during the past week with twenty-five deals in sight, which will be closed within the next few weeks.

TOLEDO, O.—Another car was this week added to the already long list handled on Motor Row, at Toledo, O. It is the Metz four-cylinder runabout, which sells at $495. The Northern Ohio Motor Car Company will handle the car in Toledo territory. A number of selling agencies will be established in Northern Ohio.

BOSTON, MASS.—Manager Frank J. Tyler, of the United States Motors Company's Boston branch, has decided to have the Stoddard-Dayton branch moved into the building on Massachusetts avenue at the corner of Newbury street, where the Maxwell, Brush, Sampson and Columbia are handled, so that all will be together.

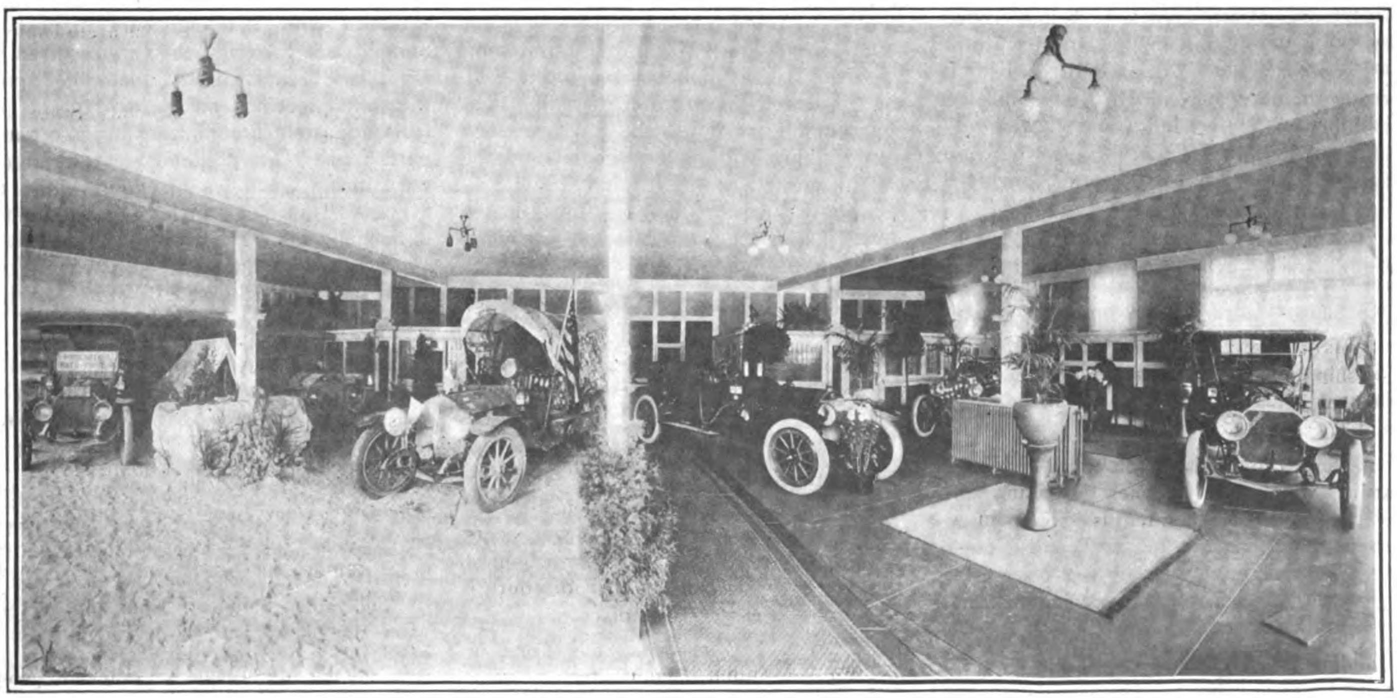
SYRACUSE, N. Y.—Automobile exhibits exercised commanding interest at the first annual exhibition, under the auspices of the United Commercial Travelers, of the Industrial Exposition and Pure Food Show at the Syracuse Armory this week. Local agents declared after the show that it had brought them a round total of $60,000.

AKRON, O.—The factory of the Goodyear Tire & Rubber Company has shut down for purposes of inventory and rearrangement to meet the demands of increasing business. During the shut-down a transfer was accomplished from steam to electric power for driving machinery, a fine electric power plant having been installed.

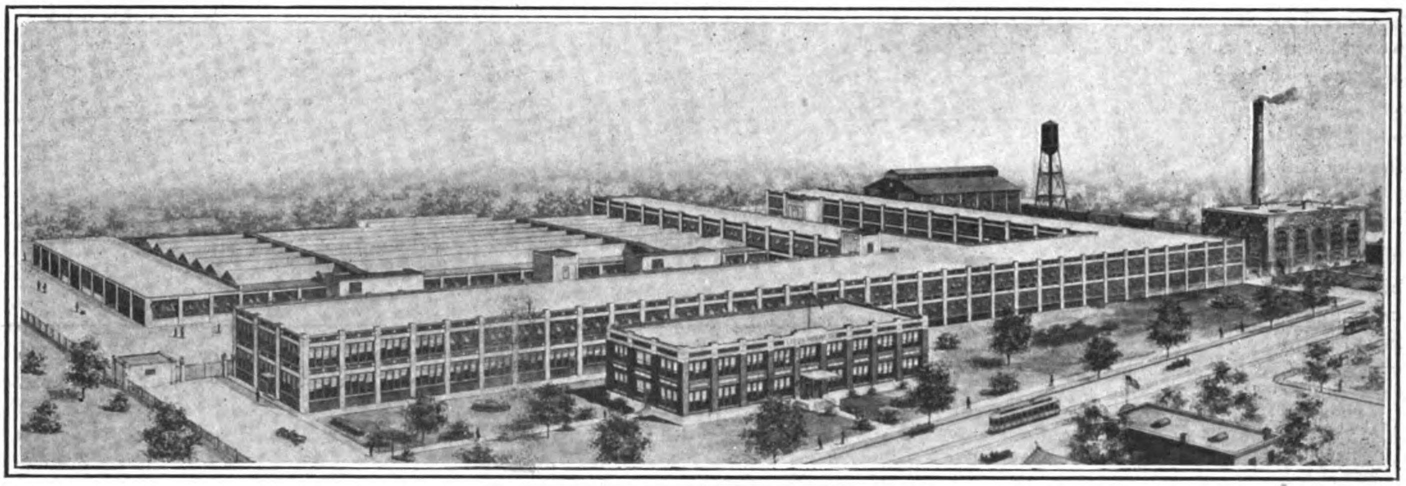
BOSTON, MASS.—On October 31 the Boston Y. M. C. A. officially opened the finest and best equipped automobile school in America, if not in the world. It is a fireproof building, three stories high, sixty feet wide and nearly two hundred feet long. It contains lecture rooms, laboratories, machine shop, garage, and every feature for the handling of the automobile with the exception of the manufacture of new cars.

NEW YORK CITY.—The Abbott-Detroit Motor Company, of New York, reports a big Fall agency business. Within the last two weeks they have signed up contracts, ranging from 50 to 250 cars each, with thirty agents, among whom are the following: Co-Operative Motor Car Company, Buffalo, N. Y.; Central Auto Sales Company, Utica, N. Y.; Abbott-Detroit Sales Company, Rochester and Syracuse, N. Y.; Ryder Motor Car Company, Poughkeepsie, N. Y.; F. W. Smith, New Haven, Conn.; Binghamton Ford Sales Company, Binghamton, N. Y.; William Stevenson Garage Company, Morristown, N. J.

INDIANAPOLIS, IND.—The fall automobile show held recently by the Premier Sales Company of this city at its sales rooms was an unqualified success, and will be made an annual event in the future. Hundreds of visitors attended the show daily and much interest was manifested. Many persons pronounced the exhibit the most striking they had ever seen. The idea of the desert scene, which occupied half the space, was taken from the Ocean-to-Ocean Tour of twelve Premier cars last summer, when the forty tourists camped out in the desert while en route from the Atlantic to the Pacific Coast. Sand, cactus and sage brush were used, surrounding the tents of the campers and two of their cars, the pilot and prairie schooner. The rest of the space was taken up with Series M models.



Fall exhibit of the Premier Indianapolis branch. On the left is reproduced some of the desert conditions encountered on the Ocean-to-Ocean tour



Bird's-eye view of the principal plant of the Lozier Motor Company at Detroit, Mich., employing eleven hundred men

DETROIT, MICH.—W. Edward Wilson, of the Wilson Body Company, died suddenly at his home here, from heart disease. He was 38 years old and was one of the most popular men in local motor circles.

DETROIT, MICH.—The Continental Motor Manufacturing Company has begun work on an addition to its Muskegon plant. The extra room is greatly needed. The plant is now running full capacity, night and day.

DES MOINES, IA.—The Brown-Corley-Ellis Company, local agent for the Marmon, Paige-Detroit and Kelley trucks, has started the erection of a two-story building at Fourth and Grand avenues which is to be completed in sixty days.

DES MOINES, IA.—George Means, a well-known Des Moines automobile dealer, was married this week to Mrs. Genevieve Tucker-Evans, of this city. A motor trip to Kansas City was the honeymoon for the newly married auto man and his bride.

DETROIT, MICH.—Work is being rushed on the new addition to the Hudson Motor Car Company's plant in an effort to have it ready for occupancy by Dec. 15. The new building is 530 feet long, 60 feet wide and two stories high. It will increase the company's floor space to 236,411 square feet.

DETROIT, MICH.—Walter E. Blaine, a draughtsman for the Packard Motor Car Company, has been declared the winner of the Flanders 20 offered by the Board of Commerce for suggesting the most suitable name for the water carnival to be held next Summer. It will be known as the Cadillaqua.

DETROIT, MICH.—The Chalmers technical convention, which was continued last week with 28 technical men from the Middle West and South in attendance, is proving so popular that the company has decided to add a fourth week to the convention program. Accordingly the sessions will not end until the week of Nov. 6.

OMAHA, NEB.—A two-story garage and sales room is being erected at Fortieth and Farnam streets for the Electric Garage Company. This is the first garage to be built in the residence district, being in one of the most fashionable districts in the city. Practically all of the garages are between Sixteenth and Twenty-fourth streets, on Farnam.

DETROIT, MICH.—William B. Wreford, formerly well known in local motor car circles, has been promoted to the position of assistant secretary of the Detroit Board of Commerce. Mr. Wreford left the automobile business several months ago to become municipal secretary of the board and in that capacity he has rendered most efficient service.

DES MOINES, IA.—The United Motors Des Moines Company, which is the State agency for the United States Motors Company, will move this week to the quarters formerly occupied by the state agency for the Buick Company. The Buick State agency has been closed. George W. Jones is the manager of the United Motors Des Moines Company.

DES MOINES, IA.—The Iowa Auto & Supply Company, the pioneer firm in this field, has announced the erection of a fine two-story building to house the concern. The new building will be on the site of the present quarters at Fourth and Grand avenues and will be the finest repository in the State. The Iowa Auto & Supply Company was recently merged with the Keystone Auto and Supply Company.

PERU, IND.—The Great Western Automobile Company of this place has brought out a new automobile body with detachable fore doors which, when removed, leave the car as a finished open touring car with no disfiguring posts nor mouldings. The compartment under the rear seat can be reached through a door at the rear of the body as well as by lifting the seat cushion. This obviates the annoyance of disturbing the occupants of the seat.

DETROIT, MICH.—The Hupp Motor Car Company has appointed Charles D. Hastings as its new general manager and the directors are satisfied that they have made a very happy selection. Mr. Hastings is given a large share of the credit for the successful development of the sales organization and his suggestions have resulted in many economies in the manufacturing end of the business. For several years before he became identified with the Hupp Company Mr. Hastings was with the Olds Motor Works.

INDIANAPOLIS, IND.—Mr. Carter, president of the Henderson Motor Sales Company, accompanied by Charles P. Henderson, general manager of the same company, Mrs. Carter, Mrs. Henderson and Miss Henderson has returned to this city after a six weeks' trip through Minneapolis, Winnipeg, Vancouver, Seattle, Portland, San Francisco and Los Angeles. Their object was pleasure, but Mr. Henderson turned part of his trip into business. Stops were made at scenic points on the Canadian-Pacific.

AKRON, O.—The first seven trucks owned by the Chicago Fire Department came equipped with Diamond wire mesh base motor truck tires and the service given by them has been such that the same equipment was specified on the nine police patrols and four fire police patrols recently purchased. On preliminary tests these must make 45 miles an hour, while an average of 35 miles an hour is maintained in making runs. The average mileage given by the tires to date has been over 15,000 miles on fire trucks and over 10,000 miles on police trucks.

DETROIT, MICH.—Frank Briscoe, who has been at the head of the Detroit division of the United States Motor Company since the corporation was organized, has gone to New York to take full charge of the company's engineering work. This necessitated his resignation as president of the Briscoe Manufacturing Company and the Brush Runabout Company and as treasurer of the Alden-Sampson Company. Hereafter the plants will be operated as units. Mr. Briscoe left for New York last Tuesday. His office will be at 3 West 61st street.

Los Angeles, Cal.—Manager Charles Cotton, of the Los Angeles Motor Car Company, Southern California, representative of the Locomobile, announced last week the removal of the Locomobile headquarters from Rice and Hill streets to spacious quarters at Eleventh and Flower streets.

Detroit, Mich.—As a part of the improvements being made at the Ford plant a complete new heating and ventilating system is being installed by the Coon-De-Visser Company. It will supply the present plant as well as the large addition that is being built, washing, heating and circulating about 750,000 cubic feet of air per minute.

Portland, Ore.—Rambling through the State of Oregon in an automobile was the way in which Mr. and Mrs. J. L. S. Snead, of the Krit Motor Sales Company, of this city, spent their honeymoon. They packed a camping outfit and provisions on their little two-passenger car and spent nearly two weeks out of doors. In this time the state was traversed from end to end and the trip cost less than $60.

Claremont, Cal.—The local speed limit has been raised from twelve to fifteen and twenty miles on hour. This was received by the Southern California motorists with joy, as the college town has been avoided of late because of the drastic measures said to have been taken against autoists who exceeded the speed limit. The raising of the limit is due to the efforts of the officials of the Automobile Club of Southern California who have been working for months with the Claremont officials.

San Francisco, Cal.—The Olds Motor Works has incorporated a branch house here under the title of the Oldsmobile Company of California. W. J. Mead, vice-president and general manager of the Olds Motor Works, has been named as president of the California branch. John H. Hagal, one of the best known automobile men on the Pacific Coast, is vice-president; R. N. Mosher, treasurer; F. E. Stewart, secretary and assistant treasurer, and D. L. Whitford, director. All five constitute the officers and board of directors of the new company.

New York City.—The Mitchell Motor Company of New York opens to-day its extensive new salesrooms at the corner of Broadway and 61st street. The space occupied by the company in its new location is much in excess of the area covered by the old sales quarters. At the same time the new service department, at 519 West 55th street, is placed at the disposal of Mitchell owners. This is a six-story building and will be entirely devoted to service purposes, specifically so far as the Mitchell products are concerned. The total area of all the floors of the building is little short of 30,000 sq. ft.

El Paso, Texas.—The Southwest Auto Company, 407 and 408 Caples Building, has embarked in business there with a capitalization of $100,000 as general sales agents for automobile manufacturers. The original incorporators are L. S. Davis, Geo. I. Waddey, T. A. Frey and L. A. Brasher.

Automobile Incorporations

AUTOMOBILES AND PARTS

Buffalo, N. Y.—Whyland-Nelson Motor Car Co.; capital, $10.000; to manufacture engines and automobiles. Incorporators: Frank A. Shoemaker, Frank W. Whyland, Joel W. Nelson.

Cincinnati, Ohio—Muhle Motor Co.; capital, $20,000; to do a general automobile business. Incorporators: Henry M. N. Muhle, John C. Miller, Ida Muhle, Mary Smith, Elizabeth Muhle.

Cincinnati, Ohio—Spring Hub Automobile Wheel Co.; capital, $10,000; to manufacture wheels for motor cars. Incorporators: James G. Blackburn, Ino H. Kruse, James T. Earle, Harry H. Weihe, Harry W. Plum, Robert Freisens, Edgar Wooley.

Columbia, S. C.—Etheredge Motor Co.; capital, $10,000; to sell automobiles. Incorporators: C. L. Etheredge, Robert L. Mitchell, E. J. Etheredge.

Decatur, Ind.—Decatur Motor Car Co. has increased capital from $250,000 to $350,000.

Grand Rapids, Mich.—Michigan Auto Joint Co.: capital, $10,000; to manufacture automobile parts, especially universal joints. Incorporators: C. E. Perkins, F. Carter.

Lansing, Mich.—Little Motor Car Co.; capital, $1,200,000; to manufacture automobiles. Incorporators: S. W. H. Little, C. M. Begole, W. S. Ballenger, W. C. Durant.

Louisville, Ky.—Clark Motor Car Co.; manufacturer of automobiles, increased capital from $30,000 to $60,000.

New York City—Bayles Sales Co.; capital, $10,000; to make and sell automobiles. Incorporators: Harry T. Bayles, Halsey K. Smith, Ansela P. Andersonn.

New York City—International Motor Service Association—to manufacture automobiles. Incorporators: W. H. Brearley, W. W. Friend, I. A. Monsees.

Norfolk, Va.—Mitchell Agency; capital, $10,000; to sell automobiles. Incorporators: H. T. Richardson, S. H. Butt, V. Butt.

Ocala, Fla.—Florida Automobile & Sales Co.; capital, $25,000; to sell automobiles. Incorporator: B. R. Hinson.

Portsmouth, Va.—Mitchell Agency; capital, $10,000; to sell automobiles. Incorporators: H. T. Richardson, S. H. Butt, V. Butt.

Portsmouth, Ohio—Portsmouth Automobile & Machine Co.; capital, $10,000; to make and sell automobiles. Incorporators: Lincoln Pool and others.

St. Charles, Mo.—Boenker Motor Plow Mfg. Co.; capital, $24,000; to make motor plows. Incorporators: H. H. Boenker, Louis Ringe, L. G. Wilbrand.

St. Paris, Ohio—Brockshire & Robinson Co.; capital, $20,000; to manufacture automobiles. Incorporators: F. M. Brockshire, W. T. Robinson, John Schooler, H. L. Pentz, H. C. Brockshire.

White Plains, N. Y.—William Marshall, Inc.; capital, $20,000; to make automobiles. Incorporators: William Marshall, Marguerite Young, John Hamilton.

AUTOMOBILE GARAGES AND ACCESSORIES

Cincinnati, Ohio—Ohib Top Co.; capital, $25,000; to manufacture and sell tops for automobiles. Incorporators: Robert F. Kroger, William Bossemeyer, Bion Place, Amanda Bossemeyer, Louise H. Bossemeyer.

Cleveland, Ohio—Burke Valve Co.; capital, $50,000; to manufacture tire valves.

Fivepoints, Ala.—Highland Garage; capital increased from $5,000 to $25,000; to do a general garage business. Incorporators: L. E. Whitehead, F. E. Whitehead.

Fremont, Ohio—Northern Ohio Punctureless Tire Co.; capital, $3,000; to make a patented tire. Incorporators: Frank E. Nieset, Lewis Nieset, John J. Nieset, L. P. Nieset, C. N. Brown.

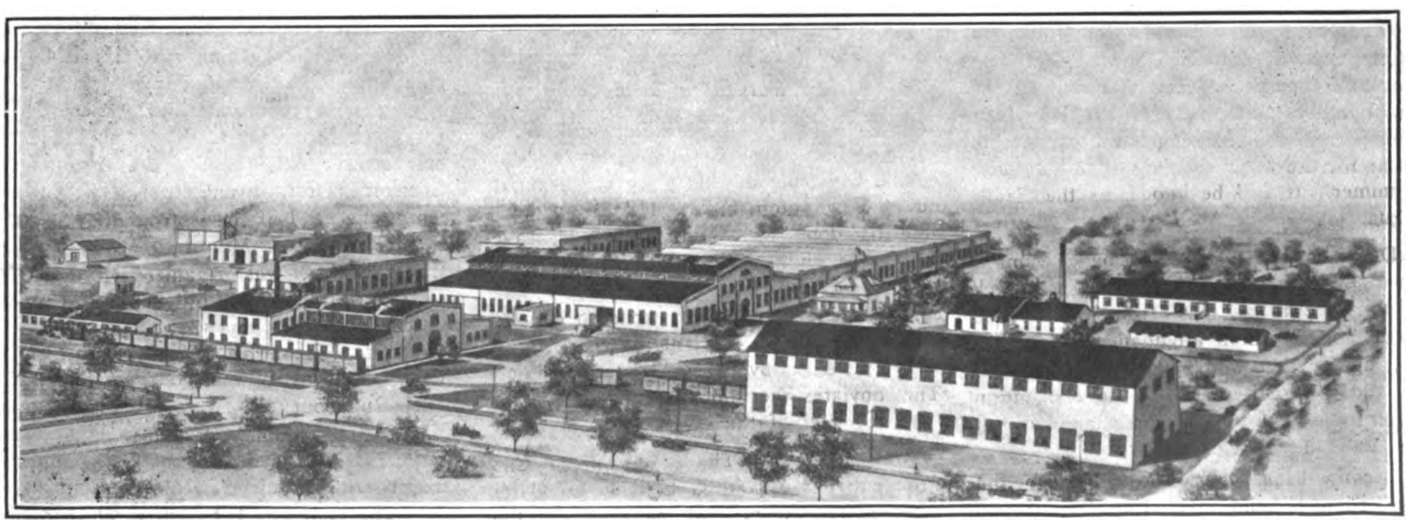
Hagerstown, Md.—Antietam Garage Co.; capital, $5,000; to do a general garage business.

New York City—La France Motor Car Co., changed name to La France Garage Co.

New York City—Auto Sectional Leather Tire Co.; capital, $50,000. Incorporators: Herman L. Biener, Isidore Scherer, Moses Scherer.

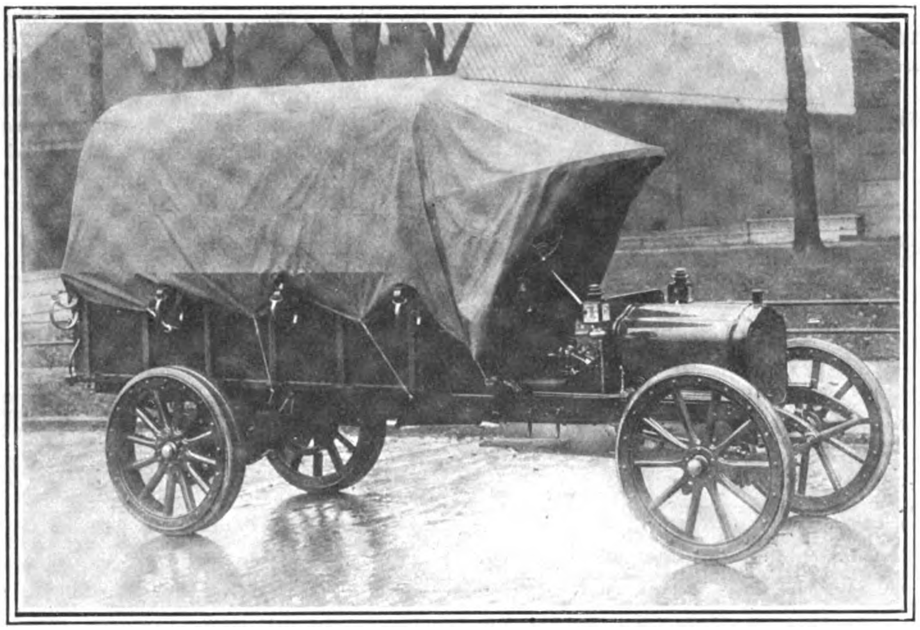
New York City—United Automobile Owners' Protective Association; capital, $25,000; to inspect automobiles and conduct a chauffeurs' agency. Incorporators: H. E. Tibid, H. A. Trebing, A. J. Davenport.

Philadelphia, Pa.—Eareckson, Hofacker & Fleming; to conduct a general garage business.



Bird's-eye view of the Plattsburg, N. Y., plant of the Lozier Motor Company, employing six hundred men

OF INTEREST to the INDUSTRY



White 1½-ton army escort wagon, built for the Government

CLEVELAND, O.—The White Company has just delivered to the Government of the United States an army escort wagon which shows a most interesting development of the motor vehicle for freight transportation in connection with military work. The wagon was built according to Government specifications, and if found successful will in all probability be used in considerable numbers by the military service. The regular 1½-ton White chassis has been used in the building of this wagon.

FREMONT, O.—Harry Bowlus, formerly of the Gramm Motor Car Company, of Lima, O., has accepted the position of superintendent of the factory of the Lauth-Juergens Motor Car Company of this place.

COLUMBUS, O.—The Eagle Motor Car Company of this city, which has been manufacturing the Eagle Roadster, has changed its name to the Union Sales Company and the name of its car to the Union 25.

MILWAUKEE, WIS.—The Beaver Manufacturing Company, which is owned and controlled by the Filer & Stowell Company, is now operating under full schedule its new modern plant covering more than 120,000 feet of floor space.

DAYTON, O.—N. H. Anderson, chief engineer of the Speedwell Motor Car Company, Dayton, O., has tendered his resignation, to take effect Dec. 1, 1911, and intends to give his entire time to his new process of rolling the teeth in steel gear blanks while hot.

OSHKOSH, WIS.—H. C. Doman has disposed of his interest in the H. C. Doman Company, manufacturing motors and engines, and will retire. The new owners of his interest are Philip H. Sawyer and Edgar P. Sawyer, well-known manufacturers of Oshkosh.

HARTFORD, WIS.—The new factory building of the Kissel Motor Car Company, in which most of the assembling will be done, will be ready for occupancy about Dec. 1. The factory is working to full capacity and the additional room is much needed to enable the concern to keep up to its 1912 schedule.

NEWCASTLE, IND.—A reorganization of the Whitesides Commercial Car Company, which is moving from Franklin, Ind., to Newcastle, Ind., has taken place, the new company being incorporated with an authorized capitalization of $31,250. The directors are L. C. Boyd, F. N. Whitesides, O. C. Saffell, T. B. Milliken and W. G. Hillock.

COLUMBUS, O.—Attorney-General Hogan, of Ohio, has rendered an opinion recently which is of interest to firms and corporations acting as agents for motor cars in the Buckeye State. It is held that when a partnership changes its name it is not entitled to the use of the old registration and number plates, but must register anew and secure different number plates.

NEWARK, N. Y.—A peremptory sale of the entire Mora Automobile plant, including sixty cars, machinery and building plant will be held Tuesday, Nov. 14, and Wednesday, Nov. 15, 1911. Bidders will be offered an opportunity of purchasing single cars. Arrangements will be made with the purchasers of the patterns to supply the owners of the Mora cars with any part desired.

DETROIT, MICH.—The differences and litigation that have existed for several years between the Timken Companies and Lindsay & Harmon, of Indianapolis, regarding the Lindsay patents on rear axle constructions, under which the Timken Companies have been operating, have been amicably settled and adjusted, and the Timken-Detroit Axle Company retains complete shop rights under these patents.

RICHMOND, VA.—Ground has been broken for the automobile factory which the Kline Motor Car Company is to erect in Richmond. The site is on the boulevard near the Fair Grounds, and the contract calls for a complete structure by Feb. 1, 1912. The plant will cost about $300,000 and will give employment to about 1,000 men when in full operation. It is said that orders have already been received for cars valued at $800,000 though no deliveries can be made until next year.

MILWAUKEE, WIS.—The Lavigne Gear Company, of Detroit, Mich., has decided to move to Wisconsin and the equipment and machinery are now being installed in buildings of the Wisconsin Engine Company at Corliss, Wis., 25 miles south of Milwaukee. The company has been incorporated under the laws of Wisconsin with an authorized capitalization of $100,000 by Charles E. Albright, George Uihlein and Norman L. Baker, of Milwaukee. The concern manufactures gears for motor vehicles and as a specialty makes a gear which is a substitute for the worm gear.

LAFAYETTE, IND.—The Esterline Company, Lafayette, nd., manufacturer of the Berdon electric lighting system for motor cars, announces the appointment of the following sales representatives: New York City, Mr. Mortimer L. Newman, 114 Liberty street; Atlanta, Ga., the Automobile Specialties Company, Mr. L. O. Surles, manager, 222-224 Peachtree street; Denver, Col., Western Engineering & Specialties Company, 1732 Glenarm street; San Francisco, Cal., the Symonds-Berle-Kirkpatrick Company; Los Angeles, Cal., the Symonds-Berle-Kirkpatrick Company; Cleveland, O., Chas. F. Saenger & Co., 210 Electric Building; Boston, Mass., the Standard Engineering Company, 53 State street; New Haven, Conn., the Standard Engineering Company, 810½ Chapel street; Waterbury, Conn., the Standard Engineering Company, 16 East Main street.

PATENTS GONE TO ISSUE

DIFFERENTIAL GEARING—Axles are rotated by gears in mesh with idlers on stud in differential housing.

1. The patent relates to a balancing gear, Fig. 1, consisting of a housing member, a primary driving gear and a casing member, the driving member being detachably secured to the housing and casing members. The housing member carries a stud, the length of which is equal to the housing diameter, and idlers are carried on the stud. The axle sections entering the gear casing and abutting the stud carry secondary driving gears, which have motion imparted to them by the idlers on the stud. The ends of the stud are held to the housing member by means of cap screws.

No. 1,006,847—To James G. Heaslet, Detroit, Mich., assignor of one-half to Walter E. Flanders, Pontiac, Mich. Granted October 24, 1911; filed July 27, 1910.

HYDROCARBON POWER PLANT—A system consisting of a number of combustion chambers and a working gas turbine.

3. The plant shown in Fig. 2 is a combination of a shaft with a system of internal combustion motors symmetrically surrounding the shaft on which is mounted, besides the motor cylinders, a working turbine. Between motor system and turbine is mounted a collecting chamber connected by passages to the motor plant. Means are provided to prevent the escape of heat from the chamber and nozzles are in the chamber directing the flow of gases from there to the turbine. A compressor turbine has its running wheel mounted on the shaft and a suction pipe leading to it. A delivery pipe connects compressor and motor system and it contains a cooling device. An annular compression chamber communicating with the delivery pipe and with the working cylinders is provided.

No. 1,006,907—To Alfred Buechi, Winterthur, Switzerland. Granted October 24, 1911; filed October 30, 1906.

SPEED-CHANGING MECHANISM—A system of regulating the gears serving for speed changing in an automobile.

5. Fig. 3 illustrated the combination, with the operating members of a speed-changing gear, of a gate-plate having one transverse slot and a plurality of longitudinal slots connected with the transverse slot mentioned, a plurality of super-imposed sliding plates movable parallel to the gate-plate and having apertures whose rear walls in the rearmost position of the plates register with the rear wall of the transverse slot of the gate-plate. Means are provided for guiding the sliding plates. A lever pivotally mounted to move in the slots of the gate-plate extends permanently through the apertures of the sliding plates, projections in these apertures corresponding relatively in position with the longitudinal slots in the gate-plate. Means are provided to connect the sliding plates with the operating members of the change-speed gear. A pedal is connected to the above-mentioned lever which has a projection. An independently pivoted cam-lever is adapted to engage the projection and to the cam lever is connected a pedal. A clutch and a brake rod are connected to the cam lever.

No. 1,006,893—To Arthur Henry Adams, London, and Marcus Charles Inman Hunter, Bedford, England, assignors to Adams Manufacturing Company, Ltd., London, England. Granted October 24, 1911; filed July 15, 1910.

TENDER FOR TRACTION ENGINES.—Attachment for agricultural and similar machines for carrying fuel.

3. The tender comprises a body carrying a water tank and vertically hanging bearing sleeves. To each sleeve a wheel is pivotally connected, and between the sleeves a fuel rack is seated on the body and held in place by the sleeves.

No. 1,006,764—to Charles F. Maloney, Wheelock, N. D. Granted October 24, 1911; filed June 20, 1910.

CARBIDE INDICATOR—An indicator showing the quantity by weight of the carbide contained in the holder of an acetylene generator.

1. The patent is of an acetylene generator with a carbide holder having a tapering lower portion, around which loosely extends an annular plate supported by springs which are mounted in stationary members. Means actuated by the movement of the carbide holder are movable along a scale with weight graduations, indicating the weight of carbide in the holder.

No. 1,006,826—to Harry C. Buschmann, assignor to Jenne Acetylene Gas Machine Company, Indianapolis, Ind. Granted October 24, 1911; filed March 23, 1911.

AUTOMATIC CONTROLLER—Circuit controller for electric motors.

2. The patent covers, in a governor, the combination with a rotating shaft, of a pair of pivoted weights surrounding the shaft and having their greatest weights at their ends, and a longtitudinally movable member provided with a pair of teeth at the sides of the shaft and midway between the weights which engage the teeth.

No. 1,006,802—to Simon Sparrow, assignor to Wagner Electric Manufacturing Company, St. Louis, Mo. Granted October 24, 1911; filed May 27, 1909.

VALVE CAGE—A type providing a tight fit for oscillating valves.

2. The patent relates to a cylinder adapted to receive a valve cage fitting tightly in the cylinder, and having ports separated by a bridge and a groove extending longitudinally from end to end of the cage and formed in the exterior surface of the bridge where the same makes contact with the cylinder bore.

No. 1,006,748—to Thomas Hall, assignor to Ridgway Dynamo and Engine Company, Ridgway, Pa. Granted October 24, 1911; filed February 11, 1911.

Newest Ideas Among the Accessories

Disco Self-Starter

THE Disco, illustrated in Figs. 1 to 5, is made by the Ignition Starter Company, of Detroit, Mich. Its principle of operation is the injection of compressed acetylene into the engine cylinders and starting on the spark by means of this highly combustible fuel. The entire installation may be understood by referring to Fig. 1. When the Disco self-starter is installed the priming cups in the motor cylinders are replaced by so-called engine valves, Fig. 2. These valves consist of a lengthened priming cup and cock, and a connection is provided on the stem, through which acetylene may be led into the valve and cylinder. The acetylene is taken from the gas tank, flowing through a gas pipe to the distributor on the dashboard, whence it is distributed to the four engine valves. Turning the handle of the distributor, Fig. 3, permits the acetylene to pass through the distributor valve contained in this part of the system (Fig. 5).

The Disco principle is said to operate on any engine which stops or balances in a normal position, i.e., in one where a spark occurs in one cylinder, if the battery circuit is closed. It is necessary, of course, that the spark be strong enough to explode the mixture, in other words, that the ignition system be in good order.

Since the same acetylene tank supplies the gas to the starter and to the headlights and lamps, provision must be made to operate these two systems independently. This is done by using a two-way gas-tank connection, Fig. 4, by which half of the gas is directed to the lighting and the other half, if necessary, to the starting system. The two-way connection is so threaded as to be capable of replacing the standard connection on the acetylene tank.

It must be understood that in conducting the gas to the distributor and engine valves rubber tubing or some other piping except copper must be used. Although

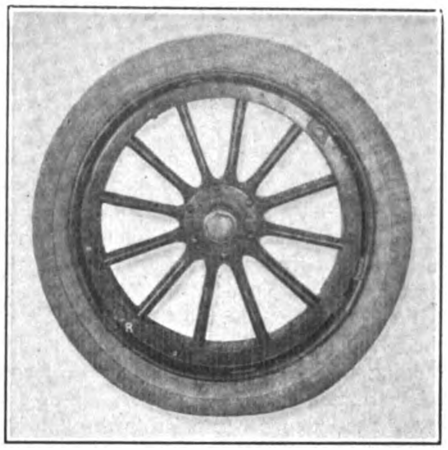

Fig. 6—Lambert remountable rim which is controlled by a single bolt

very little acetylene is consumed through the Disco system—it is said that it starts an engine 3,000 times on the contents of one tank—the influence of the gas would in time change the copper gaspipes to acetylene-copper on the inside. This is a very dangerous material to handle, as the slightest concussion might bring about an explosion.

The fact that the acetylene tank and the ordinary ignition system are used in the Disco starting system goes to make it fairly foolproof, since everybody is nowadays familiar with the caution necessary in handling these two accessories of the automobile.

Lambert Demountable Rim

The Lambert rim, which is illustrated in Fig. 6, is of the quick-demountable class. The side of wheel seen in Fig. 6 is the outside one, on which all the operations are done, and it is very simple in appearance, showing but one ratchet R and pawl, and an adjustment nut A for the purpose indicated. To take the rim off the wheel, the ratchet is turned by a special wrench having a handle of the rotary drill type. About fourteen revolutions of the nut release the bolt integral with it from its seat, and as soon as this is done the tire rim and tire are forced off their seat on the felloe rim. This is caused by the peculiar shape of the latter, which converges toward the center line of the chassis. If the tire rim and tire are put in place the action of the bolt and the nut on the wheel felloe bring felloe and tire rim into tight relation, overcoming thereby the tendency of the wedges on the tire rim, which also tend to throw felloe rim and tire rim out of engagement. The adjustment nut A is very seldom used, as it serves only to take up wear.

After the tire rim has been removed from the wheel a slight shock produced by springing it on the ground permits of taking the rim out of the tire shoe. The rim is made in two steel sections, hinged at one end and engaging in a positive-lock manner on the other. The slight shock imparted to the tire disengages the locking portions and the hinged rim sections are easily pulled away from the tire and fitted to a new tire or the old shoe after a new tube has been placed into it. Hereafter the rim and new tire are bolted onto the wheel again. The bolt, which is integral with the ratchet, is the only loose part of the Lambert demountable rim. The pawl holds the ratchet in whatever position it is brought into by means of the wrench, but if the wrench is slipped over the nut attached to the bolt the pawl is pressed out of engagement with the ratchet, so that the latter may be rotated without difficulty. The handle of the wrench is of such size as to give considerable leverage and consequent ease of operation in screwing the rim on or off.

The Lambert rim is the product of the American Rim Company, of 250 West 54th street, New York City.

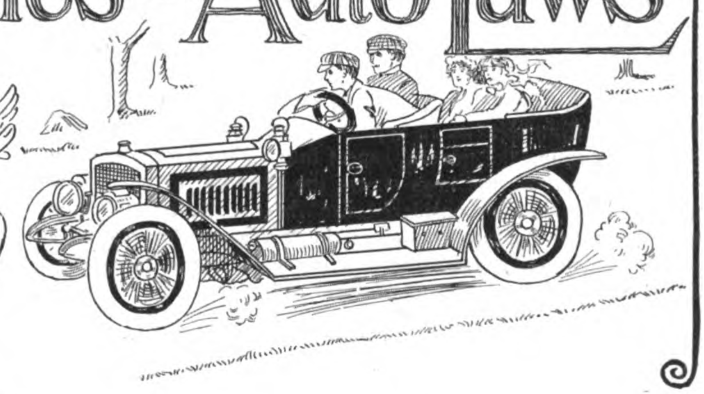
VOL. XXV : NEW YORK—THURSDAY, NOVEMBER 9, 1911—CHICAGO No. 19

THE AUTOMOBILE

Inconsistencies in Auto Laws



EXISTING laws covering the operation of automobiles in the various states of the country have, by reason of numerous inconsistencies, proved trying to motorists in numberless instances. Not only is there a lack of uniformity in the laws of widely separated states, but even where they are contiguous there is often the widest divergence in the text and construction of the laws.

Nobody has questioned the police power of any of the states to regulate the speed and to lay down rules for automobiles and all other kinds of traffic. Neither has a voice been raised against the taxation of automobiles as personal property, precisely the same as horse-drawn vehicles or pipe organs or mining stock. No one has heard any protest against any law that has for its object the protection of the public from reckless driving or that tends to insure competence in paid drivers. But when it comes to subjecting interstate traffic of automobiles to the action of thirty-nine different sets of automobile traffic laws, patience ceases to be a virtue. Almost all these laws differ radically one from the other, and it would take something more than a Philadelphia lawyer to understand them all. Even then his understanding might differ from that of Si Perkins, constable of Prunty's Corners, or that of Squire Squidgins, J. P., who might be called upon to sit on his case.

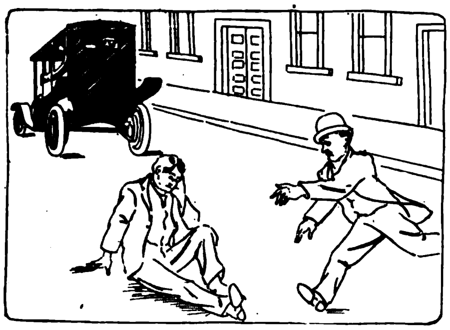
In fact the automobile laws of almost every state in the Union have been construed and declared by the courts of the various states diametrically opposite at the same time.

Thus the legal situation is highly mixed and there is no possible way for a man to make absolutely sure of no interference by the authorities. For instance, in New York State the statute says that 30 miles an hour continued for one-quarter mile is presumptive evidence of reckless driving. And yet nobody in New York City is sure that he can drive his car at all without coming in contact with the law.

Another instance recently noted in Virginia was the case of the Glidden tourists who were arrested at Harrisonburg for driving at 10 miles an hour when the State law says that 20 miles an hour is not illegal.

There are thirty-eight states that have special automobile laws, and the District of Columbia also rejoices in a set. There is no national law on the subject, and the preponderance of legal opinion seems to be that there can be no such unless Congress wishes to consider the taxing and regulating of one variety of interstate traffic without touching any of the rest. As this is prohibited by the constitution, the chances for a national law seem unflattering.

As an instance: If a horse-drawn truck, loaded with merchandise, traveled from New York to Washington, no question



Felony in New York to escape after accident

would be raised as to its rights to use the roads without paying any national or State license. If a gasoline motor were substituted for the horses there would be no more reason for taxing it than the horse-drawn wagon. The states might assume the right to regulate the automobile coming from another state, but the national government could not do so, according to the opinion of well-versed legal lights.

Therefore, the remedy for the jumble into which the legal aspect has been mixed seems to lie in a common understanding among the states. Already steps have been taken that look to such an ultimate result.

The present status of the law in the thirty-eight states and District of Columbia as it applies to automobile operation is treated. Dividing the general aspect into eight phases or heads, a careful digest of the laws shows the situation to be unsatisfactory. The heads considered are these: Registration and fees; license to operate and fees; the law as to non-residents; equipment required; regulation of chauffeurs; speed provisions; penalties and the legal status of local ordinances.

Regarding Registration and Fees Therefor

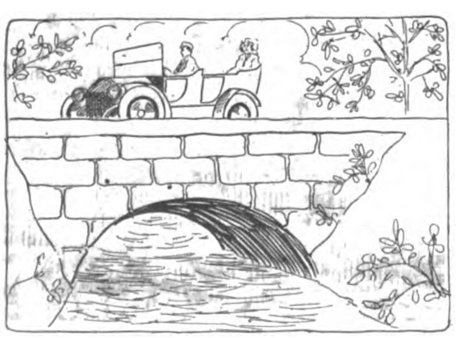
With reference to registration and fees connected with that section of the laws there is a wide divergence of text and construction. In Alabama registration is required on October 1, when numbers are assigned and certificates issued. The fee is from $7.50 to $20, depending on horsepower. Manufacturers and dealers are required to register, the fee being $100 in their cases, with an additional tax on the horsepower of all cars belonging to them. This is $1 per horsepower under 20 horsepower and 50 cents per horsepower over that number. Registration number must be carried at the rear and only one set may be displayed.

In Arkansas yearly registration is required December 31; two sets of number plates must be shown, front and rear, and a metal seal issued by the Secretary of State must be carried. General registration is commanded upon the parts of manufacturers and dealers. The fee charged is $5 per car.

In California the license plate must be shown in the rear, while on the front lamps the numbers must be displayed. Fee, $2 a car.

Connecticut also requires annual registration; one set of numbers and fees based upon 50 cents a horsepower. Commercials must pay $5 for cars of 1000 pounds' capacity or less, and $2 for each additional 1000 pounds. The law also makes a charge of $1 for each motor tested by manufacturers on the public highways.

Delaware makes it obligatory to show number plates in front and behind. Registration fee, $5 a car.



North Carolina—5 miles an hour over bridges

In the District of Columbia the number must be shown behind and $2 is charged for each identification tag.

Florida's law is similar.

In Illinois number plates must be shown front and rear, and the fees range from $4 a car of less than 25 horsepower to $10 for one of more than 50 horsepower. General registration is required for manufacturers and dealers, fee $15.

Indiana only charges $1 for registration.

In Iowa the fees range from $8 for a car less than 20 horsepower to any additional amount reckoned at 40 cents a horsepower. After four years' payment on a car the fees are cut in half.

Kansas, Montana and South Carolina have made no legislative provision for registration, and consequently charge no fees for that particular thing.

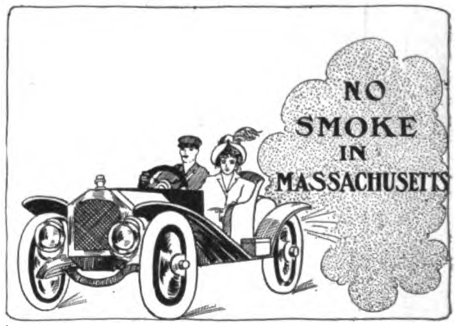
Kentucky charges fees from $10 to $20, depending on horsepower, and requires numbers to be shown front and rear. Maine's law makes the fees from $5 to $15 for passenger automobiles and $10 for trucks.

In Maryland the fees are from $12 to $24; in Massachusetts, $5 to $25; Michigan, $3, and if the license is taken out after August 1 it is $1.50.

In Minnesota registration is commanded every three years; fees, $1.50.

Missouri law says that number plates may only be shown in the rear. Fees range from $2 to $12. The Nebraska motorist must pay $2 a year. In Nebraska the fees run from $10 to $40; dealers are taxed $40.

In New York annual registration February 1. Fees range from $5 to $25, and after four years' payment they are cut in half. Trucks and deliveries cost $5 a year to register. From August 1 to February 1 the fee is half the statutory amount for one year.



The old Bay State laws punish smoking

New Jersey fees for registration are from $3 to $10, and in North Carolina $5, with renewal privilege at $1. North Dakota, $3; Ohio, $5; Oregon, from $3 to $10; Pennsylvania, $5 to $15. The Pennsylvania law provides that manufacturers and dealers' cars shall only be operated by duly qualified and licensed drivers.

In Rhode Island the fee is from $5 to $25, with $2 each for commercial cars and $50 for manufacturers and dealers.

South Dakota charges $1 for registration; Tennessee, $2: Texas, 50 cents; Utah, $2.

Vermont charges $1 a horsepower and reduces the rate 25 per cent. a year for the second and third registrations. Virginia fees range from $5 to $20, with a dealers' fee of $50.

Washington exacts $2 for registration; West Virginia and Wisconsin the same amount.

It will be found that in a general way the regulations as far as registration are concerned are pretty much alike except as to the amount of the fees charged. Annual registration is definitely commanded in twenty-five of the states and is understood in six others. Three states do not require it, in addition, of course, to the other eight, which have no automobile laws at all.

Fees range from 50 cents in Texas to $40 in several of the states where a maximum charge is imposed for registration.

The main idea involved in this section of the law is to get a complete record of ownership so as to insure identification. Several states reduce the fee after the original entry.

As to Licensing Automobile Drivers

The second phase of the automobile laws is that which provides licensing to operate. In Alabama only chauffeurs come under the rule, save that no person under 16 years of age may run a car unless accompanied by an adult.

In Arkansas, California, Florida, Illinois, Michigan, Missouri, Ohio, Pennsylvania, Utah and West Virginia there are no licenses required to operate cars except in the case of paid chauffeurs.

Indiana, Iowa, Kansas, Kentucky, Montana, North Carolina, North Dakota, South Carolina, South Dakota, Tennessee, Texas, Washington and Wisconsin exempt even the chauffeur from registration or the necessity for taking out a license.

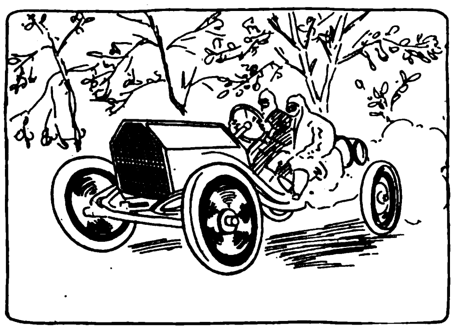
In Connecticut all operators are licensed annually, fee $2. In Delaware the fee is $5. District of Columbia, $2; Maine, $2; Maryland, $2; Massachusetts, $2, with renewal 50 cents; New Hampshire, $3, with renewal $1; New Jersey, from $2 to $4, depending on horsepower; Oregon requires all operators to register as chauffeurs; Rhode Island, $1; Vermont, $2. In Virginia the annual license for the car's owner is included in the registration fee and is construed to cover members of the owner's family. Chauffeurs and others are taxed $2.50.

In the other states which have laws children are prohibited from driving.

Of the thirty-eight states considered thirteen make no restrictions whatever as to the driver, while ten tax the chauffeur only. In eleven states all operators must register, the fee ranging from nothing in Oregon to $5 in Delaware.

Rights and Duties of the Non-Resident

This section of the laws is one of the most important of all, as it touches upon the safety of the public as well as motordom. It is conceivable that a man of notorious reputation for carelessness, drunkenness or some other vital fault in New York, might go to Indiana, for example, and drive the private car of some wealthy man, when he could not do so on account of his record in his home state.



In Texas road racing is prohibited by law

The section of the laws that deals with the status of non-resident motorists shows some signs of uniformity.

In Alabama non-residents, upon compliance with the law of the state of their residence and displaying registration number, are granted the same exemptions that are accorded residents of Alabama in the state in which the non-resident lives.

In Arkansas compliance with the law of one's own home state, displaying numbers and carrying lights is enough to gain exemption for the visitor. California does not mention the lights in granting exemption. Connecticut laws are similar, but provide for revocation of the exemption upon conviction for violation of any clause of the Motor Vehicle Act.

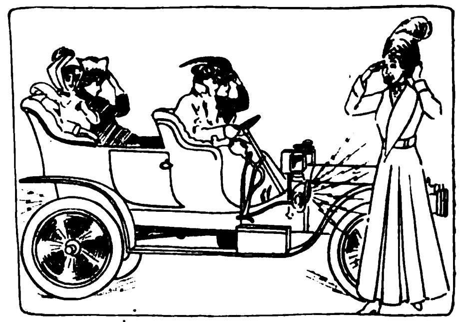
Reciprocity is the keynote of the Delaware provision as it is in the District of Columbia. Florida exempts registered automobiles for 30 days. Illinois does the same for 60 days in any one year, except in the case of foreign corporations.

The exemption in Indiana is wider and is granted to all cars that have complied with the law at home. Iowa has adopted a similar policy, save that it requires a reciprocal treatment. Kansas makes no provision in its law. Kentucky only asks that the car be legally clean at home.

In Maine an exemption of 30 days is granted to cars that have complied with home laws and driven by a person duly licensed to operate the automobile. Maryland partially exempts cars for two periods of 7 days each in one year providing non-resident's tags are secured from the commissioner of motor vehicles.

Massachusetts exempts visiting cars from registration for 10 days a year on a reciprocal basis. Half rates are charged visitors in summer who overstay that period.

Michigan requires that home law be satisfied and reciprocity extended to her own citizens.



New Jersey prohibits noise on its highways

Minnesota places a 30-day limit on visitors without registration.

Missouri's limit is 20 days; Montana makes no provision; Nebraska, 30 days; New Hampshire, 10 days, but car must be driven by duly licensed driver. Half rates are charged visitors for the three summer months. New York is on a reciprocal basis except as concerns foreign corporations.

New Jersey: Non-residents are not exempt except under special driver's license, which remains in force for eight consecutive days or four periods of two days each; license issued by Commissioner of Motor Vehicles, or appointed deputy; fee, $1. Non-resident corporations specially licensed to penetrate 15 miles into the state when registered at home and upon payment of $100.

North Carolina allows outside automobiles to pass through without penalty. Others are not exempt.

North Dakota exempts registered cars and Ohio demands reciprocity as well as home registration. Oregon has a limit of 30 days; Pennsylvania, 10 days and reciprocity; Rhode Island, 10 days and provides that the exemption shall be revoked in case of violation of speed regulations.

South Carolina does not cover this point.

South Dakota and Utah require that visiting cars shall be registered at home in order to claim exemption.

Tennessee and Texas make no exemptions.

Vermont, Washington, West Virginia and Wisconsin grant reciprocal exemption and require home registration.

Virginia exempts visitors for two periods of 7 days each in any year.

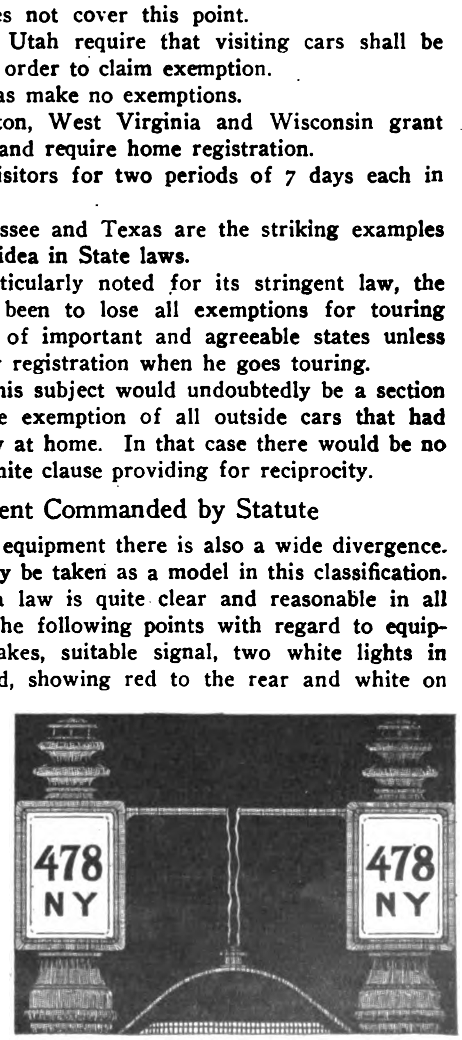
New Jersey, Tennessee and Texas are the striking examples of the non-reciprocal idea in State laws.

New Jersey is particularly noted for its stringent law, the effect of which has been to lose all exemptions for touring Jerseyites in a score of important and agreeable states unless the Jerseyite pays for registration when he goes touring.

The ideal law on this subject would undoubtedly be a section that provided for the exemption of all outside cars that had complied with the law at home. In that case there would be no necessity for any definite clause providing for reciprocity.

Equipment Commanded by Statute

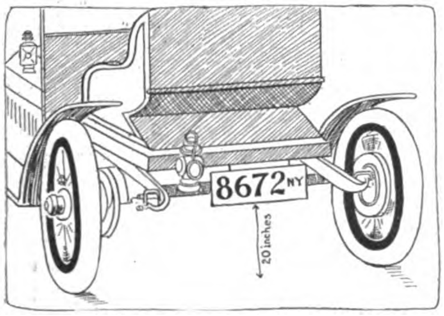
Under the head of equipment there is also a wide divergence. The Alabama law may be taken as a model in this classification. In fact, the Alabama law is quite clear and reasonable in all respects. It covers the following points with regard to equipment: Adequate brakes, suitable signal, two white lights in front and one behind, showing red to the rear and white on the number plate. Lamps must be lighted one-half hour after sunset until one-half hour before sunrise. The Arkansas statute differs from that of Alabama in that it provides that the front lamps must be visible 200 feet away and that the number must be



Arkansas requires numbers on front lamps displayed on the glass front of the lamps. The motor must be shut down when the car is left standing.

California provides for showing the registration number on the lamps. In Connecticut there must be two sets of brakes and the muffler is required to be used after 9 o'clock at night within the limits of cities or boroughs.

Delaware requires two white front lights and a red tail lamp. In the District of Columbia a lock is commanded in addition to the usual provisions and a muffler is required. Whistle or signal and two lamps are all that are required in Florida.



Some States insist on rear tags being at least 20 inches above the ground

In Illinois there must be brakes, signal, two white lamps in front and one in the rear showing red behind and illuminating the number plate so as to make it visible 150 feet. As a detail, it is ordered that this plate shall clear the ground by at least 20 inches.

Brakes, lamps and signal are required in Indiana, Iowa, Kansas, but in the latter there need be only one front lamp. Kentucky demands brakes, signal and lamps, the front pair of which must carry the registration number. This is the law that caused such a rumpus among the Colonels recently, and which is still in the courts for construction.

Two brakes and a muffler are the features of the Maine law, while the Maryland statute provides that the front lamps be visible 200 feet. Unreasonable noise and smoke are prohibited in Massachusetts, while Michigan lays the ban upon anti-skid devices of all sorts except in wet, slippery weather. The muffler must be used in Minnesota within village or town limits.

Missouri only demands the three usual lamps with brakes and signal. Montana makes no special provision for equipment. Nebraska requires brakes, signal and one or more lamps in front and a red light behind. The muffler must be used in New Hampshire cities and villages.

New York makes the statutory requirement for brakes, signal and three lamps, the rear light illuminating the number plate so that it shall be visible 50 feet away.

Smoke is banned in New Jersey and lights only are required in North Carolina. North Dakota provides for signal and two lamps, one on either side. Ohio's law is similar to that of Alabama. In Oregon the registration number must be shown on the face of the front lamps. The Pennsylvania provision is like Alabama's. Rhode Island's is also, except that the use of the muffler is provided. South Carolina requires at least one white light in front, otherwise the law is the same as Alabama. South Dakota follows the lines of Alabama. In Tennessee only a signal is required. In Texas one lamp and a signal fills the legal requirements. Utah is like Alabama. In Vermont a muffler is required, lamps must bear registration number and a lock is ordered so that the car cannot be set in motion when left alone.

One lamp in front, at least, and a lock, as above, is necessary in Virginia. Washington commands that at least one white lamp carrying the number of the car shall be used. A muffler is also required in cities or villages.

West Virginia's law provides for a speedometer and for front lamps bearing the registration number. In Wisconsin at least one white lamp in front is required.

In all the states except Tennessee that are provided with automobile laws the statute commands the use of a lamp or lamps at night. In all but three states brakes and signals are required. Throughout the foregoing text, unless it is specifically excepted, the law requires lights, brakes and signals.

The Alabama law is excellently framed and covers the main points distinctly. This form of the law has been followed by eighteen states and probably represents the best general line to be followed. In the details of equipment practically all the states differ from one another. There are no two exactly alike, although, as has been said, eighteen are substantially so.

Two front lamps, distinctly visible for a reasonable distance, with one in the rear, showing red behind and shining sidewise upon the number plate, adequate brakes, suitable signal and a due regard for the use of the muffler would seem to embody the essentials of a model law.

Chauffeurs in the Legal Contemplation

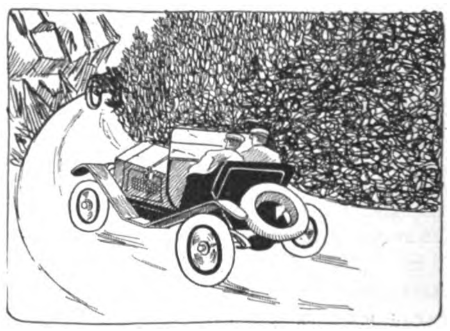
The phase of the law that deals with chauffeurs is badly scattered. The Alabama law on this subject is moderate and effective. It provides for annual registration and requires that applications must be endorsed by three reputable automobile owners. A badge is issued to successful applicants, which must be worn while operating the car. The fee is $5, with a charge of $2.50 for renewals. Non-resident chauffeurs are exempt if they have complied with the law of their home states.

In Arkansas the fee is $1, and grafting is prohibited specifically. California charges $2 for registration and non-residents are not exempt. No special provision is made for chauffeurs' registration in Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey and Rhode Island, in each of which the law requires all operators to register and take out licenses before operating automobiles.

In Indiana, Iowa, Kansas, Kentucky, Montana, Nebraska, North Carolina, North Dakota, South Carolina, South Dakota, Tennessee, Texas, Washington and Wisconsin, the subject is not covered in any way.

Florida charges $2 for registration and exempts non-residents engaged in driving non-resident cars for 30 days.

Illinois examines chauffeurs and the fee is $5, with renewals at $3. In Massachusetts a fee of $2 is required for examination. Michigan, $2, non-residents exempt if home law has been complied with.



Only 10 miles an hour in New Hampshire when approaching a curve

In Minnesota the fee is $3, with renewals at $2. Non-residents are exempt for 60 days. Licenses may be revoked upon third conviction. Missouri, fee, $1.50. The fee in New Hampshire is $5, with renewals at $1. In New York the chauffeurs are required to take an examination and the fee is $5 with renewals at $2. The certificate bears upon its face the photograph of the chauffeur. After February 12, 1912, non-residents will be exempt upon complying with home laws.

Ohio charges $2 for registration. Non-residents are exempt. Oregon requires all operators to undergo registration and charges a fee of $2. Pennsylvania also charges $2. So do Utah, Vermont and West Virginia. Virginia charges $2.50.

Speed Limits of the Various States

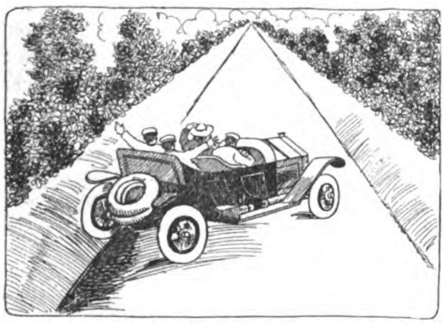
It is a patent fact that no person should operate an automobile unless thoroughly competent to do so. Therefore, the trend of opinion is setting toward the registration, examination and licensing of everybody who drives a car. On this basis the law of Connecticut is clear and definite and probably expresses the idea of a fair, safe law as well as any other statute.

Speed provisions vary as widely as do those covering any other phase of automobiling. A rate of 30 miles an hour for one-quarter mile is deemed presumptive evidence of recklessness in Alabama. Arkansas places the speed limit at 20 miles an hour for 1-4 mile, with 6 miles an hour as the maximum speed in rounding a corner. California says 20 miles an hour, with 4 miles an hour as the limit on dams, sharp curves or grades. Connecticut marks the limit at 25 miles an hour, with 10 miles an hour on curves and crossings. Delaware 20 miles an hour; District of Columbia the same. Florida only requires a reasonable and proper rate without mentioning maximum figures, and insists on 4 miles an hour on bridges, curves and crossings. In Illinois 25 miles an hour is the limit, with the usual restrictions of speed in built-up sections. Racing is prohibited.

Indiana limits speed to 20 miles an hour, and provides for 6 miles an hour in passing a horse or other draft animal. Iowa says 25 miles an hour and Kansas cuts it down to 20 miles an hour. Kentucky sets the limit at 20 miles an hour; Maine, 25 miles; Maryland, 25 miles; Massachusetts, 20 miles, and provides for the sounding of horns at intersections of the road and at curves where the road is hidden from view. Michigan, 25 miles, with a limit of 10 miles an hour in passing pedestrian or horse. Minnesota, 25 miles an hour. Same for Missouri, Nebraska, New Hampshire, New Jersey, North Carolina, Oregon, Rhode Island, Vermont, West Virginia and Wisconsin.

Montana sets the limit at 20 miles an hour. New York allows 30 miles an hour, as does North Dakota; Ohio makes it 20 miles; Pennsylvania, 24 miles; South Carolina, 15 miles; South Dakota, 20 miles; Tennessee, 20 miles; Texas, 18 miles; Utah, 15 miles; Virginia, 20 miles; Washington, 24 miles.

In practically every state that has automobile laws there is a specific requirement for reasonable and proper speed. This is construed to be less than 15 miles an hour in South Carolina, and less than 30 miles an hour in New York, North Dakota and a few other states. The rate of 25 miles an hour is deemed reasonable in nearly a score of states, while another score insists that 20 miles an hour is about right, with due care in driving. Almost every state considered designates and specifies certain conditions under which speed must be reduced far below the maximum figures. Almost every state specifies curves, bridges, crossings in this category, and many of them make it statutory to shut down when passing draft animals.



Non-skids not allowed on Michigan's crowned roads, except when snow or ice-covered

The idea of a speed limit is a difficult one to handle. It is conceivable that a speed of 40 miles an hour might not be unsafe or unreasonable in some sections, and it is absolutely certain that 12 miles an hour is wildly unreasonable and unsafe in certain other sections. The essence of the law is to protect the public, the automobilists, property and the roads, and reasonableness is the fundamental principle involved. If racing were prohibited and reasonableness insisted upon in the matter of speed it would seem that arbitrary speed limits might be abolished.

Penalties for Breaking the Laws

As regards penalizations, the range runs between a fine of $1 to imprisonment for felony, depending upon the gravity of the offense and the state in which it is committed.

In Alabama speed infractions or drunkenness may draw a fine of $500, or six months in jail, with sweeping revocations of registration and license. Arkansas makes it $100 for speeding and $200 for racing; California, $250 or 30 days; Connecticut, $500 or 30 days; Delaware, $200 or 3 months; District of Columbia, $250 or 6 months; Florida, $250 or 60 days; Illinois, $200; Indiana, $200; Iowa, $500 or 2 years; Kansas, $100; Kentucky, $50; Maine, $50 or 10 days; Maryland, $500 or 500 days in jail; Massachusetts, $100; Michigan, $100 or 30 days; Minnesota, penalty for misdemeanor; Missouri, $500 or 60 days; Montana, $100 or 60 days; Nebraska, $100 or 60 days; New Hampshire, $100 or 30 days; New York, $500 or 5 years; New Jersey, $500 or 20 days; North Carolina, $50 or 30 days; North Dakota, $50; Ohio, $100 or 30 days; Oregon, $150 or 75 days; Pennsylvania, $200 or 1 year; Rhode Island, $500 or 90 days; South Carolina, $100 or 30 days; South Dakota, $50 or 30 days; Tennessee, $100; Texas, $100; Utah, misdemeanor; Vermont, $200 or 6 months; Virginia, $10 minimum or 30 days; Washington, $100; West Virginia, $250 or 30 days, and Wisconsin, $25.

Only 6 miles an hour in Indiana when passing horse-drawn vehicle

The minimum punishment ranges down to a reprimand. In New York it is felonious under the Callan act for the driver of a car to run away after an accident. Drunkenness is construed to be vastly more serious in the driver of a car than it would be under almost any other circumstances.

The technical penalties provided for violation of the speed limits are generally severe when it is considered that speed alone is not necessarily an evidence of reckless driving. It is admitted and urged by the majority of automobile owners that the provisions against recklessness cannot be made too strong. Take the recent Glidden Tour as an example. Virginia has a limit of 20 miles an hour, and the schedule of the big cars was 20 miles an hour. It is not possible to average that rate of speed without going 30 miles an hour in favorable localities. By the same token South Carolina's limit is 15 miles an hour. If either of these laws was enforced there could never be any fast touring in either state.

In the matter of the status of local ordinances it may be said that as a general thing they are prohibited where the state law covers the premises. In many of the states the posting of signs is provided. As a general thing the laws of the various states provide speed limits which must be observed in cities and villages.

London's Horse 'Bus a Thing of the Past

London, Nov. 1.—The curtain was rung down on the scene of the horse-drawn omnibus in the streets of London on Tuesday, October 31, and to some old Londoners the end was a tragedy. On the day mentioned every horse-drawn omnibus was cleared from the London roads, thus putting an end to a traffic system whose romantic reign has extended back over a long period of years in the English metropolis. The change from horse-flesh to petrol, which was inaugurated in 1904, has been even more rapid in its revolutionary character than the most sanguine prophets anticipated. The first motor-omnibus started in London ran from Peckham to Oxford Circus.

Two motor omnibuses were put upon trial at Hastings, England, to ascertain the actual running cost of such vehicles. During 1909 the expenses of the 'buses averaged 23 cents per mile each. This outlay was cut to 20 cents per mile during the fiscal year ending recently. These 'buses were not, however, of the very latest types and it is estimated that 18 cents per mile will cover the running expense of the most modern pattern of vehicle.

Lining up for the start on Broad Street in front of the office of the Newark Star

Twenty-seven Perfect in Newark Run

NEWARK, N. J., Nov. 3—In the golden sunlight of a perfect Autumn afternoon, twenty-seven of the thirty-four entrants in the Newark Star Endurance Contest drew up at the finish line with perfect scores. The run was conducted by the Newark *Star*, under the auspices of the Newark Motor Club. The route covered a 127-mile circuit through the most picturesque part of New Jersey.

Promptly at 6.45 in the morning, Mayor Haussling, the honorary starter, fired a shot from a revolver. This novel method of starting an automobile run sent off a big Mais 2 1-2-ton truck, which was followed by a Johnson 3-ton truck and the other cars. Each car carried an official observer, who kept accurate account of the time consumed in work on the car, as penalties were imposed at the rate of 1 point a minute, or fraction thereof. The rules provided penalties at this rate for every stop made outside of Newark control except at Hackettstown fuel control, where water, gasoline and oil could be obtained. If these were taken on at any other point on the route a penalty of 3 points was imposed. Each contestant was required to cover the entire route in exactly 7 hours from the time of starting under penalty of disqualification. The time for the trucks was 12 hours. For each minute early or late at the Newark control a penalty of a point a minute was incurred.

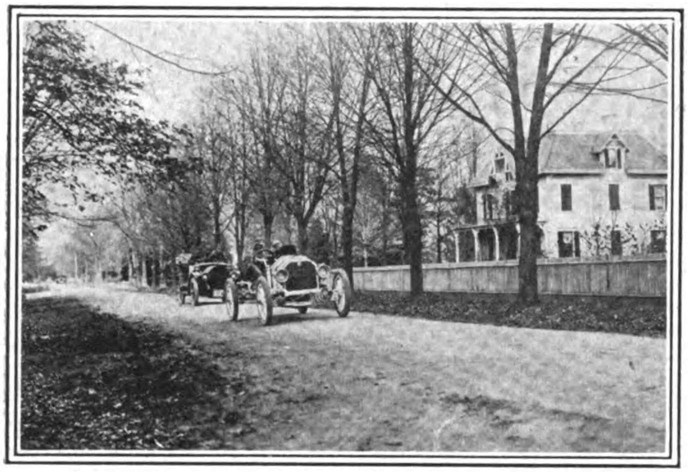
Crowds gathered to watch the cars checking in at the finish

Auburn making good time on the last leg of the 127-mile route

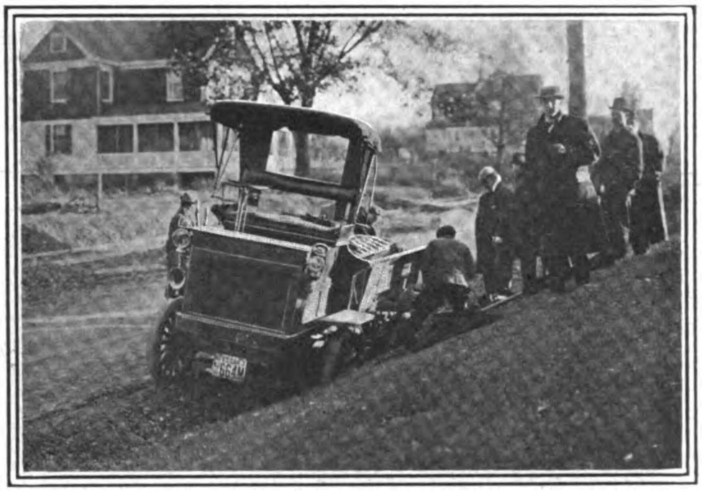
The first mishap of the run fell to the lot of the Johnson truck, which, in trying to avoid a stone-pile on one side of the road and a post on the other, plowed into someone's front lawn and sank in up to the hubs. After five hours' work the truck was released and proceeded, drawing up at the finish line at 1.45 a. m.

The Mais truck had no trouble until it struck a water-break at German Valley, and bent its drive shaft, which took two hours to repair. The truck finished at 9 P. M.

The McFarland No. 1 and the Jackson runabout were late in leaving the Newark control, checking out at 7.12, although their time counted against them. No. 1 became stalled on Hamburg Mountain and No. 22, a Maxwell, at Charlottesburg, on account of tire trouble. The latter was stalled on Northfield road as well, the penalties for the two occasions being two points. No. 3, the Paterson, had two punctures at Newton and a blow-out at Hackettstown. This car arrived so much ahead of time that it was penalized eight points. The Cutting, No. 6, driven by Frank Kramer, the bicycle champion, was fined one point because of a stalled motor. The Auburn runabout, No. 15, was penalized two points for stopping the car near the tape. It was one minute behind time. No. 4, the Metz runabout, was fined one point for faulty equipment. The Schacht, No. 29, was fined one point for stopping the motor in Hackettstown.



As the cars approached the checking station at Newton



The Johnson truck was laid out early, but continued to the finish

Each of the cars making perfect scores received a beautiful silver cup, and each driver a handsome medal. Horace A. Bonnell, manager of the Automobile Board of Trade, had charge of the contest. The summary:

No.	Name of Car.	H.P.	Driver	Penalties
2	Jackson	30	J. D. Nicol	0
5	Ford	22	C. B. Wyckoff	0

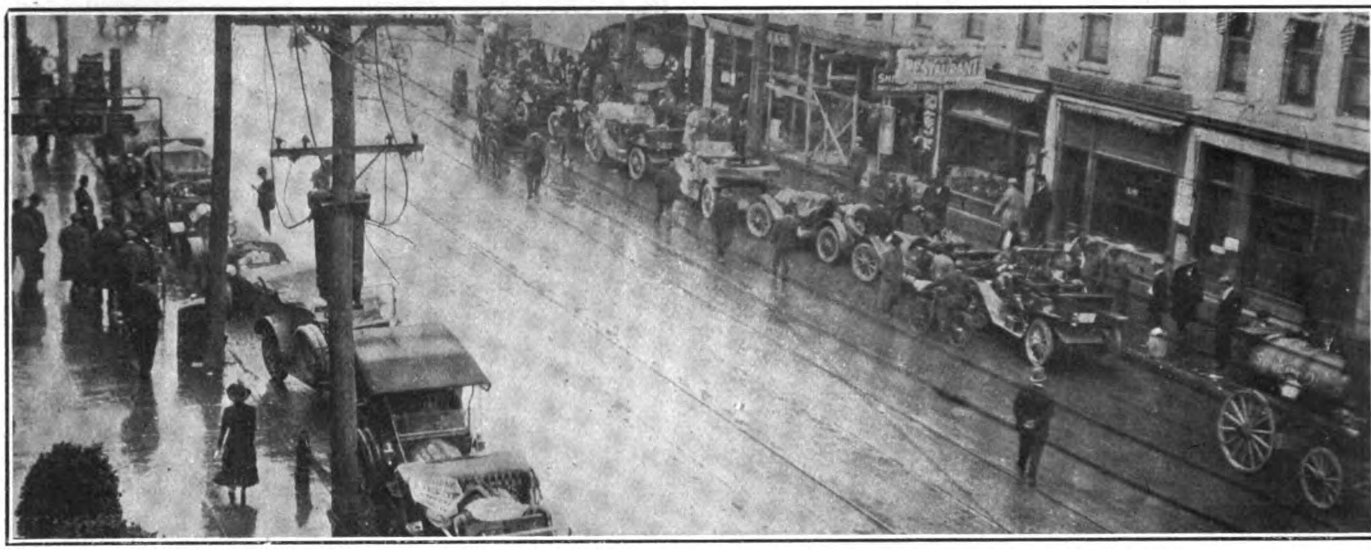
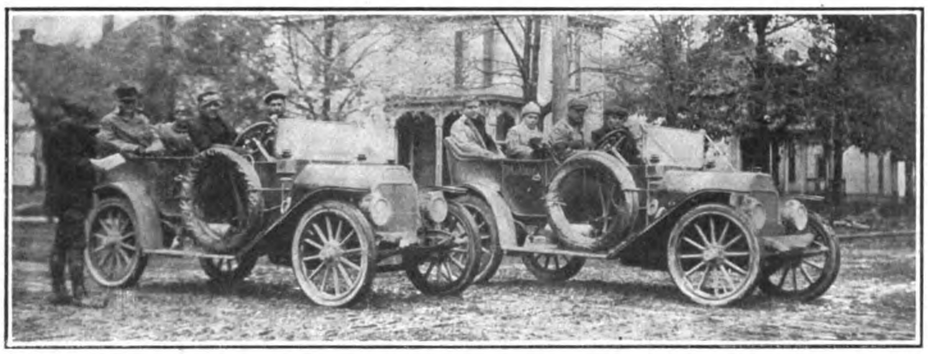
Molines, Staver and Grout Winners



Scene when the contestants in the reliability run of the Chicago Motor Club stopped at the noon control at Lexington, Ky.



Moline team in touring car class—No. 2 clean score

CHICAGO, Nov. 5—That automobiles are being made better each succeeding year is well demonstrated by the performances of the seventeen cars that contested in the 7-day reliability run of the Chicago Motor Club which endd in this city this evening. Of the seventen cars that started in the run nine reached Chicago to-night with perfect road scores.

A perfect road score meant that the car had traveled on its 20 or 18-mile-per-hour schedule during the run and that no adjustment had to be made on the car during the road work. Two or three years ago it was a wonder if one car made a perfect road score, but to-day under stricter rules over 50 per cent. of the cars have ended with clean scores for the road work. This is what appeals to the car owner, for what owner wants to be held up along the road for any car troubles? He does not mind having to make some little repair in his garage at the end of the day's run, but does object to having to stop in the middle of a muddy road or on a city street to make such a repair.

But the winners of perfect road scores did not necessarily mean winners of the contest. After the road work was over each car had to take its brake test, its clutch test, its motor test and was given a technical inspection of one-half hour in which every broken, bent or loose part on the car was looked for and penalties, according to the fixed penalty rules of the American Automobile Association, imposed. After it was all over two cars were tied for the touring car trophy and a winner was declared in the runabout class. A Moline and a Staver tied in the touring car division. Both had perfect scores on the road, perfect scores in the brake test, perfect scores in the clutch and motor tests and perfect scores when the technical inspection was completed. They share equal honors and each will receive a trophy. Salisbury drove the Moline which carried No. 2 banner and Knudsen drove the Staver which was No. 10 in the test.

In the runabout division another Moline was the winner. It was driven by J. A. Wicke, who has piloted cars of this make in several Glidden tours and in previous runs of the Chicago Motor Club. He had a perfect road score, passed perfect brake, clutch and motor test, but lost 4 points in the final inspection. He had a water leak at the top of the radiator where the return pipe to the motor is attached to the upper tank part of the radiator. The victory gives to his company the Van Sicklen trophy put up a year ago and which trophy has to be won three times before becoming the permanent possession of the winner. Last year the Moline tied with the Fal on this trophy and by the agreements then made the possession of the trophy for the first year was to be determined this season. As the Fal was not a contestant in this run, the winning of the trophy for last year goes to the Moline by default. The Moline now has two legs on this trophy.

In the touring car division there were nine contestants and in the runabout class, eight, the complete penaliziations for road-work, brake tests, clutch and motor tests appearing on the opposite page.

In addition to the winners of the touring car and runabout

divisions there were two other winners. The first was the winner of the team trophy, a team consisting of any two cars of the same make whether in the touring car or runabout divisions having the lowest score. The winning team is made up of two Molines, Salisbury with a perfect score and either Van Dervoort or Wicke, with 4 points each, making a total penalty of 4 points for the team.

The fourth trophy was the economy trophy carried off by No. 107 Grout, driven by Halbert. This trophy was donated by the Standard Oil Company and was won outright. It was given to the contestant showing the best efficiency performance under the economy formula of the club. This formula takes into consideration the weight of the car, the distance traveled and the gasoline consumed. The product of fuel used and distance traveled is divided by the weight of the car. In this formula it does not necessarily follow that the car making the trip on the least gasoline is the winner; in fact, Bergdoll used a few gallons less than the Grout, but was several hundred pounds lighter.

All these results were not reached without a process of elimination. First, there came the long tour itself, a journey of 1355.7 miles through five States, with night stops at Indianapolis, Louisville, Cincinnati, Columbus, Detroit and Grand Rapids, which eliminated eight of the cars. Then came the brake and clutch tests Saturday morning, which still further reduced

the field, while the technical examination as conducted by F. E. Edwards, George W. Gaidzik and supervised by David Beecroft, completed the task of evolving the winners.

To the Moline belong the chief honors of the long contest, for in addition to tying for the touring car cup and winning the Van Sicklen trophy in the roadster section and taking the team prize, all four Molines went through with perfect road scores. Three of these were penalized in the technical examination. Van Dervoort's No. 1 Moline was given 4 points for a loosened radiator support. The Wicke Moline roadster also drew 4 points for a leaky radiator union, while the Boone Moline roadster was given 54 points for a broken starting crank bracket and a loose radiator support.

The Staver-Chicago came into the limelight through the fine work of Knudsen, who not only had a perfect road score but also handled his car so well that the technical committee could find nothing wrong when it was subjected to a rigid test. The other Staver was sixth in the final rating, its main trouble being a front wheel bearing which cost it its road score and brakes in that test.

Halbert in the Grout started in the test with the idea of winning the Standard Oil Company's fuel economy trophy, which last year was taken by the Cunningham. The Grout was a class winner in the Chicago economy test last Spring and Halbert was out to repeat. After he lost his perfect score the second day he devoted all his time to saving fuel, with the result that he put his big roadster through the run on a fuel consumption of 77 gallons. This was a trifle more than was used by the Bergdoll, but the weight of the Grout enabled it to top the list.

When the tour was completed it was found that perfect road scores had been made by No. 2 Moline, No. 10 Staver-Chicago, No. 1 Moline and No. 5 Halladay in the touring car class and by No. 100 Moline, No. 101 Moline, No. 102 Oakland, No. 103 Velie and No. 105 Bergdoll. Of the others, the Abbott-Detroit and the National roadster did not finish, the former withdrawing at Niles, Mich., the last day, because of the broken spring, while the National roadster overshot a turn near Hobart and was stuck in the sand, being left there over night by its owner, Paul Strauss, who was satisfied to seek shelter in a neighboring farm house.

Notwithstanding the fact that only two of the cars went through the entire contest with perfect scores, both road and technical, the results of the trial are something of which the entire motor industry may be proud. Most of the penalties were brought about by spring troubles, and in two instances the elimination can be traced entirely to accidents. The Oldsmobile Autocrat was running perfectly until a gasoline connection sprung a leak going into Washington Court House last Tuesday. This necessitated taking off the body to repair the damage, which of course meant a big time penalty. Then, to add to the misery, the big car, while leaving Washington Court House, skidded passing a team and dropped partly into a ditch, getting in a position where it could not secure traction which made it necessary to get a team to climb out. This brought on the bulk of the Oldsmobile's penalties.

With the Case it was running perfectly until leaving Detroit. Avoiding a woman getting off a street car, the car hit a curb, which resulted in penalizations that put it out of the running. The big Abbott-Detroit can trace its fall to a spring breaking while inside the city limits of Cincinnati. Dan Boone probably would have gone clean with his Moline had it not been for a weak dry cell which made trouble for him while starting on Wednesday. Boone cranked so hard he broke the starting crank bracket.

Another source of trouble was caused by broken fender irons, several being penalized for loose fenders and broken brackets. It is figured that some make mistakes by drilling holes in the fender irons, which weaken these parts and cause breaks. Instead of drilling holes, it is suggested to clamp irons to the brackets so as to resist jars and strains of a long run.

Brakes also caught some, but it is a remarkable fact that the report shows that on every car so penalized that one of the brakes was working well. Six caught demerits here. Where one brake was holding well the other was not so good.

Turning to the other side of the picture, one finds that not a single case of engine trouble developed among the seventeen cars on the 1355-mile journey. Every engine was hitting on all four cylinders in the motor test Saturday morning, despite the severity of the run. The National was penalized for carbureter adjustments and perhaps some might claim this to be engine trouble, but here there are extenuating circumstances. Strauss, driver of the National, is the owner of the car, and this was his first contest. In starting from Chicago he discovered the carbureter was not set for those conditions, and he had to change it three times before the engine ran right.

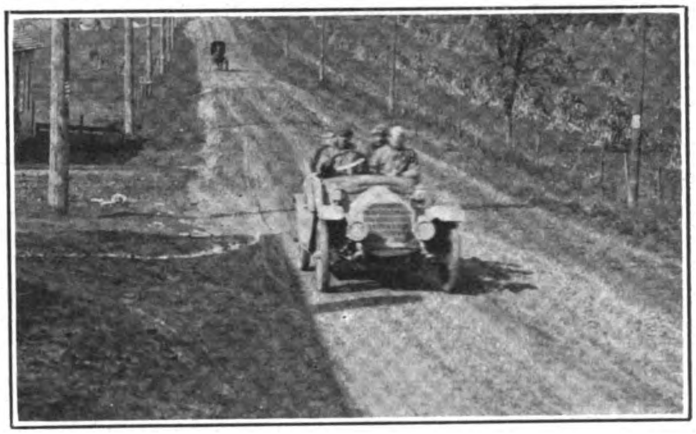
Not a case of axle trouble was reported. Before the run started the technical committee examined each car, taking the measurements from the felloe of the front wheel to the felloe of the rear one at the ground, and allowing 1-4-inch variation. Looking over the axles at the finish of the run it was found that each trimmed to 1-16 inch. No case of a broken wheel was reported, whereas in previous tests it was discovered that there were weaknesses. No leaks in radiator construction were unearthed, Wicke's penalty being for a leaky connection.

If the Chicago Motor Club had tried to order varying weather and road conditions in order to give the cars a test that would include everything in these categories it could not have succeeded better. As far as Indianapolis the weather was balmy and roads good. Then it sprinkled from Indianapolis to Louisville, although the stone roads were so good it made little difference. Going from Cincinnati to Columbus the roads were heavy because of rain, and the weather cold and disagreeable. From Columbus to Detroit there was a stretch of road that should make the States of Ohio and Michigan ashamed of themselves. From Toledo to Detroit the going was so abominable that it was necessary to change the routing.

From Detroit to Grand Rapids the weather was cold and the skies cloudy. The roads, too, were not of the kind found in southern Indiana and Kentucky, but still not so bad as to worry anyone. It was on the final day of the tour that the prize package was delivered. Leaving Grand Rapids under a cloudless sky, but with the temperature so far down that the tourists were in danger of being frostbitten, the tour had not gotten more than 20 miles out of town when traces of snow were discovered. The farther the tour progressed the deeper became the snow until the climax was reached at Niles, Mich., where an 18-inch snowfall was encountered. The conditions somewhat resembled those that attended the running of the New York-Paris race. This snow belt, however, disappeared in the afternoon, and the last traces were lost at New Carlisle, 45 miles from Chicago. From that point into Chicago the cars were kicking up dust and the weather had moderated so that the trip really was enjoyable. It was hard getting into the city because south of Gary the old Hobart road was torn up, making a detour necessary, while the usual course from Gary into East Chicago was blocked, making it necessary to go to Hammond before straightening out for the dash for the last tape.

The tour from Columbus Wednesday morning to Chicago Friday night saw the elimination of only two of the cars that had perfect scores up to that point, and those two dropped the same day, Thursday, going from Detroit to Grand Rapids. The Abbott-Detroit lost out when a gasoline line clogged and on top of this came the spring trouble which had started in Cincinnati. The Case was put out in Detroit, when it encountered the street car incident. On Wednesday the No. 9 Staver and No. 7 Oldsmobile were penalized 5 to 2 points, respectively; on Thursday the Case drew 4 points, the Abbott-Detroit 118, the Grout 53 and the National 11. On the last day the Oldsmobile drew 6 more points and the Grout 38, while the Abbott-Detroit and the National withdrew.

Grout No. 107, winner of the economy test

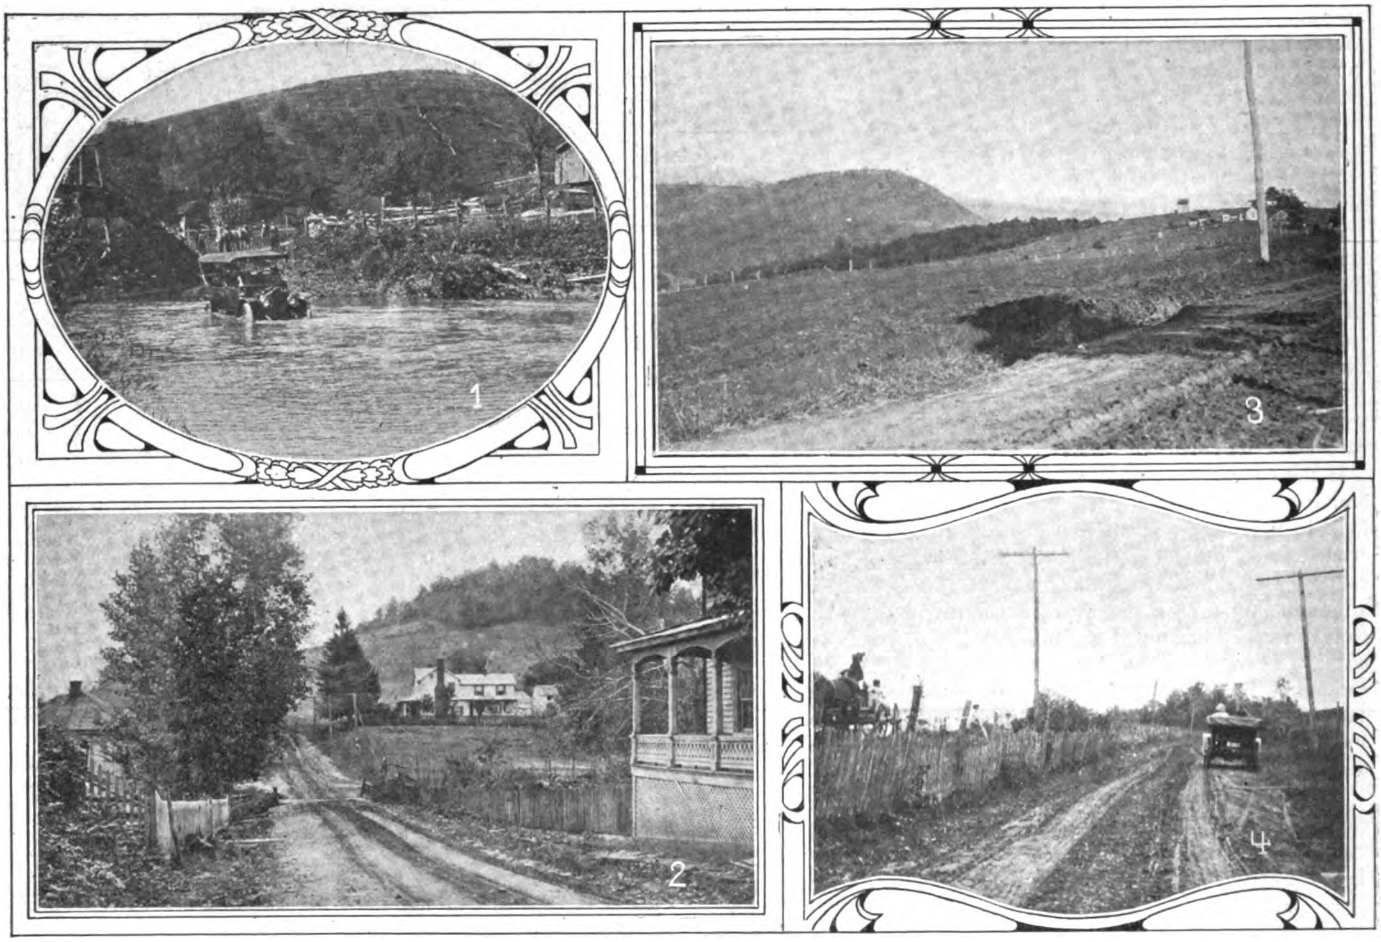


Stretch of excellent road outside of Dayton, O.

Oakland, No. 102, which tied for second place in roadster class

Stopping to put on chains, 30 miles out from South Bend, Ind.

Road Conditions Truly Indicate the



1—Back Creek will long be remembered by the Glidden tourists
2—Near Fairfield the road looks better than it is in reality

3—Leaving Roanoke the road is largely red clay and generally rough
4—Rough spot near Midway, but vastly better than it is a mile ahead

CERTAIN portions of the so-called National Highway are jokes and most of the imitations of roads included in the main Eastern route to the South are located in Virginia. On the other hand some of the best stretches of road between New York and Jacksonville are also in Virginia. Therefore, a ride across the Old Dominion involves all the pleasures and pains ordinarily to be met with on an automobile tour and many that come under the head of extraordinary.

There are miles and miles of fine macadam, stone roads and excellent dirt highways; there are also many miles of clay road, fair in dry weather and all but impassable when it is wet; dozens of miles of excessively rough and uncared for road: two score fords of varying width and depth and a score of toll-gates.

Speaking of the latter it may be said that the toll-gates are thickest where there is the least apparent reason for them as judged by the character of the roads. This, however, is a well-known characteristic of toll-roads.

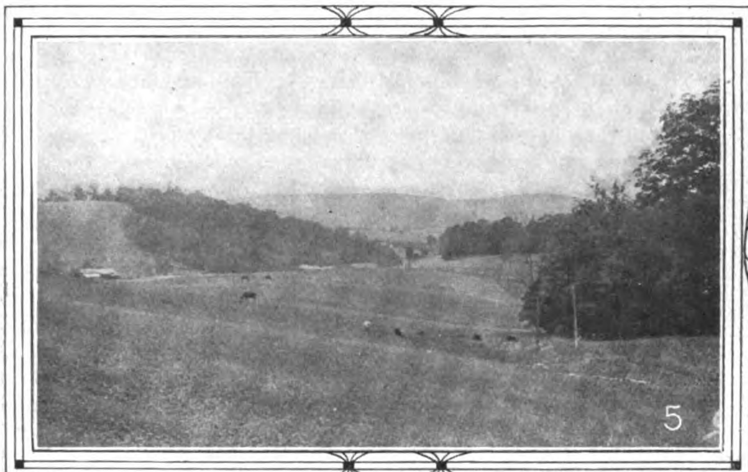
In preparing for a run through Virginia, the tourist would do well to provide an ample supply of anti-skid chains, the same being not less than six chains, so that if bad weather should intervene he will not have to abandon his car in the hills and proceed by train. He might have to do it anyway if the fords happen to be unusually deep.

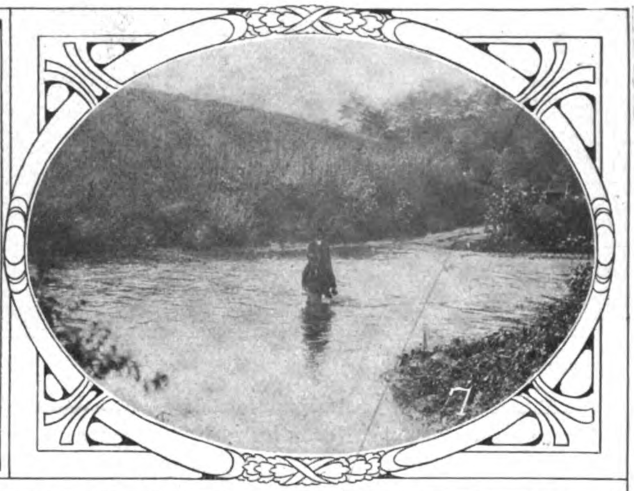
The improved section of the highway across the State is mostly north of Staunton. The worst parts of the road are south of the Natural Bridge to within 8 miles of Roanoke and south from Roanoke to the North Carolina line. A good part of these roads was built by General Greene in the Revolutionary War period and slightly improved by Stonewall Jackson and General Lee in the Civil War time and shows few traces of improvement since. In the poverty-stricken mountain section, where the people live by hunting and nutting, raising only enough razor-back pork and garden truck to supply their own excessively simple needs, the roads do not warrant the name.

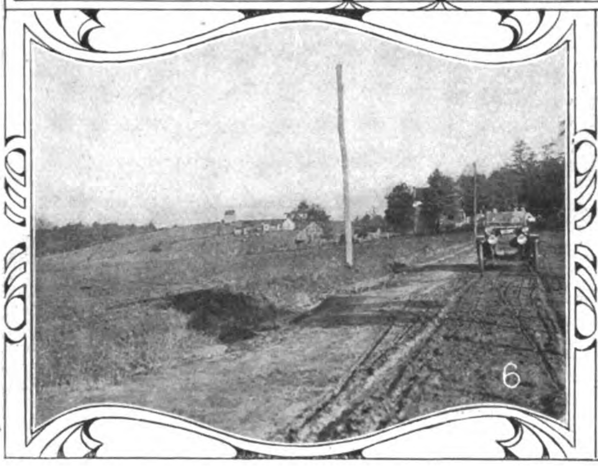
Wherever the roads are good in Virginia and as a general proposition, elsewhere, the people are prosperous, intelligent and thrifty. Where they are bad, opposite living conditions obtain.

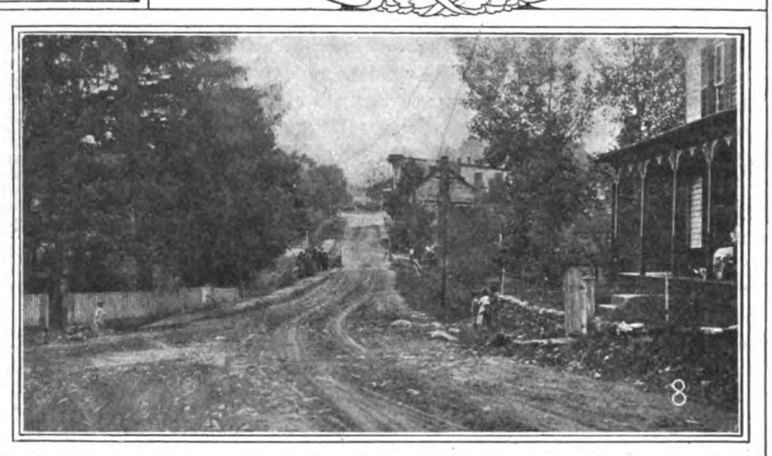
The difference between the country people of the Shenandoah Valley and those of the Roanoke Valley is startling. In the Shenandoah the farmers and horticulturalists raise as fine apples and fruit as can be found anywhere on earth. The members of the recent Glidden Tour sampled the produce all along the line from New York to Jacksonville and they unanimously award the palm for fine apples to the Shenandoah Valley. In the Roanoke Valley, outside of, and entirely separate from, the big, busy, thriving city of Roanoke, the condition of the people is lamentable. When the caravan passed their way, the only glimpse caught of the mountaineers was when the cars traversed some cross-road and for a fleeting moment the tourists saw groups of lanky, uncouth men, usually mounted and universally carrying long rifles strapped across their shoulders. Some of them were questioned and it was learned that little or no agricultural produce

Measure of Virginia's Prosperity









5—The Shenandoah Valley presents scenes of pastoral beauty
6—Near Rocky Mount—a typical section of the best roads in the locality
7—Little Chestnut Creek is likely to cause trouble in wet weather
8—Roads are generally good entering and leaving Virginia cities

was grown for market and the chief sources of income were the chase, guiding parties of hunters and seeking wild nuts in the woods. Education is a negligible quantity and physical attractiveness is wanting. Needless to say, the roads through this section are horrible.

Virginia, nevertheless, understands the value of good roads and paradoxical as it may seem, the State and counties have done an immense amount of work toward securing them. Just what progress along this line has been made can only be appreciated if one made a trip through the State several years ago and then again this Fall, noting the differences and improvements.

It is 109.8 miles from the Virginia-West Virginia line to Staunton, following the route of the Glidden Tourists. The road enters the Old Dominion 2 miles south of Rippon, W. Va. Almost the first thing the tourist will notice is a small ford, just across the State line. This could be bridged with a stone culvert at little expense and to the great advantage of users of the road. The road surface is good, being composed of stone base and fairly well maintained. There is another ford a little further on that should be bridged and then the tourist comes to the first toll-gate. Berryville, a place of 1,000 inhabitants, is the first settlement to be reached in Virginia.

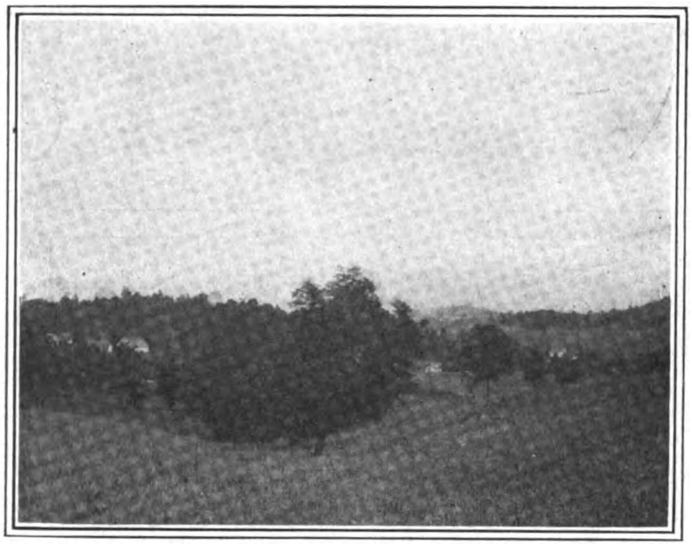
Every foot of the country south from this place was battleground during the Civil War. Each hill was the scene of a fight; each valley was once the stage setting for war in its most terrible form. Even the toll-gate just outside Berryville was once the center of a wild struggle between Mosby and Custer.

The road continues good, despite the toll system for many miles. The road corporations, in which it is said that the State of Virginia is a large shareholder, are chary about spending good money in bridging fords and water holes, but there is evidence that much work has been done to keep the roads in good condition.

Winchester, lying at the gate of the Shenandoah Valley, is rich in historic association. The town and its tributary section are also rich in almost everything else that goes to make up the sum total of human well-being except that it has no real hotel. The people of Winchester are all associated with agriculture in one way or another and as intelligence has been applied to the pursuit of agriculture in this territory, everybody has money and the town and territory own nearly 1,000 automobiles.

From Winchester to Staunton the tolls amount to $4.75 and except in spots roads are good enough. Through the battlefields of Winchester which were taken and retaken seventy times, according to local lore and historic record, the road traverses Cedar Creek, Fisher's Hill and Newmarket, all of which witnessed sanguinary struggles and the road itself was followed by General Sheridan when he made his celebrated ride from Winchester to the point 20 miles away where his troops were being crushed by the gray legions.

The way leads through Kernstown, Stephens City and Middle-

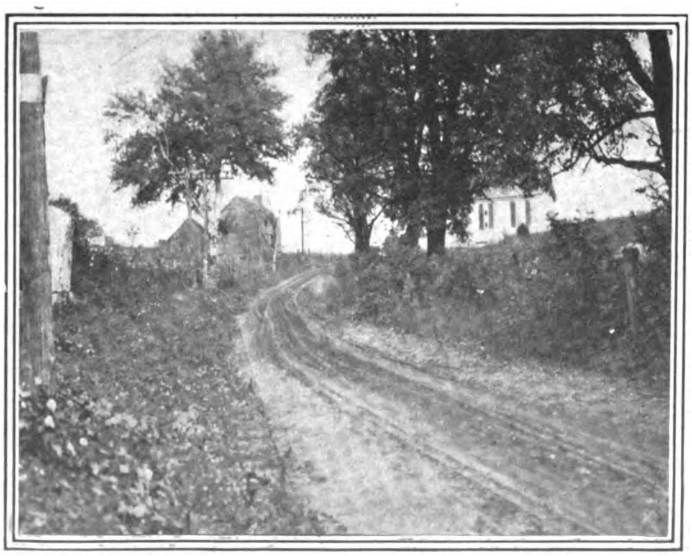


One would hardly expect to find such a scene near Harrisonburg

town to Strassburg, and skirting the hillside of the mountains to the East, passes along the North fork of the Shenandoah river through Tom's Brook, Maurertown, Woodstock, Edinburg, Hawkinstown and Mount Jackson. The stone pike is fine all along here, but upon approaching any of the little towns and villages it will be noticed that the road becomes very rough and in passing through the towns, there is little evidence of an improved pike. This is particularly true after getting South from New Market and Lacey Spring and approaching such places as Harrisonburg.

Harrisonburg is a funny little village. The land about town is poorer than the average in the Shenandoah valley and the people are on a par with the land. It might almost seem as if the treasury was bare and that not a cent more could be wrung out of the natives by the ordinary processes of the tax-collector. Outside of the fact that the road entering Harrisonburg is worse than it is anywhere in the valley, making fast progress a physical impossibility, a small, non-assertive sign at the town limits states that the speed limit is 8 miles an hour. It is probably within the realm of possibility to drive 12 or even 15 miles an hour if one cares nothing for his car. The spirit of Harrisonburg was delightfully displayed when the Glidden Tour passed through.

A large thick individual, wearing a black beard and dressed after the mountaineer style, deftly placed his hat over the warning sign when the first car came along. When six or seven cars had passed, this fellow sought a telephone and advised the officials at the next toll-gate to hold up the caravan.



Winding country road near Greenville—this is full of small bumps

It is possible that some of the cars did make 10 miles an hour in going through town and later their drivers had to pay the fines assessed. Harrisonburg was richer by the sum of $39.45 as the net result of the tour.

Mount Crawford, 6 miles to the south, also has an unenviable reputation but none of the tourists were stopped or fined.

From Mount Crawford to Staunton, the stone pike is good.

Staunton, which is pronounced as if it did not have a u in its first syllable, is a prosperous, lively and progressive place, of about 12,000 inhabitants. It is quite an educational center and is the home of the Staunton Military Academy and various female schools. Its attitude toward publicity can be accurately gauged from the single circumstance that when the Glidden Tour rolled into town, it was greeted by the paraded cadet corps of the military school at Present Arms. Staunton owns a large number of automobiles and is not in any way in sympathy with the attitude of such places as Harrisonburg.

The mileage from Staunton to Roanoke is 90.8 and it should only be essayed after a dry spell of weather. The road out of Staunton is excellent macadam for nearly 5 miles, being succeeded by rough dirt roads, that are not bad in dry weather. The road begins to climb immediately after leaving Staunton and in the first hour, the huge bulk of the Blue Ridge begins to loom in prospect. But after passing Greenville the road improves and

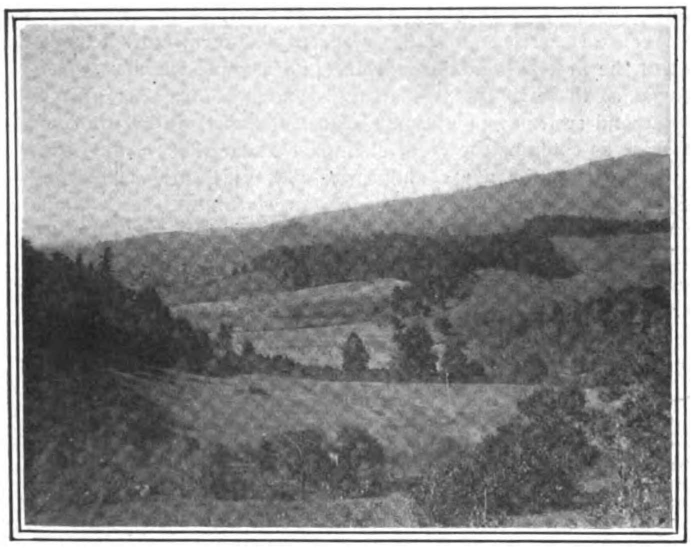
The back-bone of the Blue Ridge makes progress slow and uncomfortable

there is ample evidence of considerable highway work. This is particularly noticeable in the reduction of grades and straightening of the road just outside of Greenville.

The first dose of clay is encountered south of Midway and from there to Fairfield and Timber Ridge, high in the hills, the way would be uncomfortable in wet weather. There has been considerable grading, cutting and draining in the construction of the road from Timber Ridge into Lexington. This quiet university town is the seat of Washington and Lee University and the Virginia Military Institute and is proud of the fact that the bodies of Generals Lee and Jackson rest within its borders. An intensely interesting half hour may be spent in seeing the tomb of Lee. After the Civil War, General Lee was elected president of the university and died in 1870. His body rests in a chapel on the campus, furnished with so much plainness that it tells the story of the South's poverty after the war with wonderful distinctness. In the sanctuary of the chapel there is a full length figure of the great soldier, lying at rest, attired in the uniform of a full general. In the crypt, where his body actually is buried, a candle burns on the stone floor in front of the masonry that contains the clay of Lee.

Leaving Lexington, there is a good macadam road for 4 miles after which follows 7 miles of the roughest highway of the trip. The summit lies only a short distance from the end of the macadam. From the high point the road winds up and down between the hills which narrow the valley almost to the size of a canyon. Then comes 5 miles of good macadam which brings the tourist to Natural Bridge. From the road, Natural Bridge is a disappointment. In fact it can not be seen at all, but by paying $1 a head, tourists may stop at the hotel located there and walk down below the bridge. It is a great hollow cut in the limestone by water action and the arch is high enough to contain a skyscraper building.

There is a tremendous down-grade immediately after leaving the bridge and extending spasmodically to Buchanan, where the road crosses the headwaters of the James river. This road is graded in sections but otherwise unimproved. It is classed as a dirt road but in reality it is red clay, mixed with native earth and in wet weather is so slippery that a pedestrian can barely stand upon it. Woe be unto the automobilist who is obliged to change a tire in a rainstorm thereabouts. Nobody has yet shown the nerve to erect a toll-gate on this stretch of road. Purgatory Mountain has been robbed of most of its terrors through the improvements that have been made in and close to the village of Buchanan. In dry weather the foregoing stretch of road is generally passable at very moderate speed. In wet weather the tourist takes his life in his hand when he attempts it.

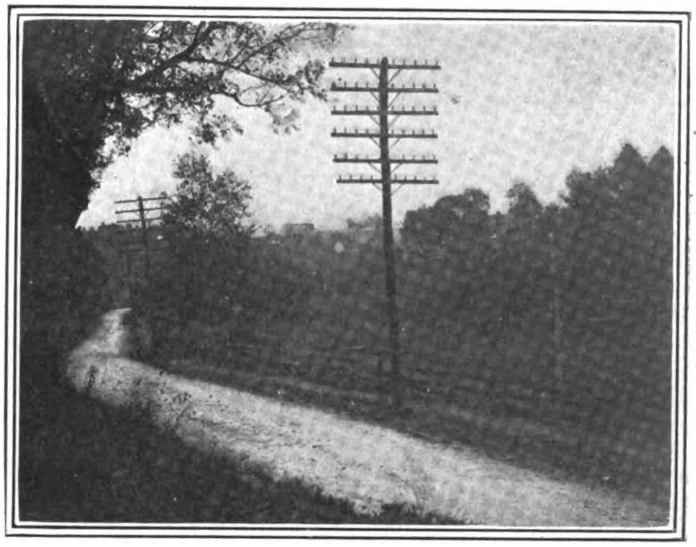


Magic scenic effects are presented panoramically in the Shenandoah

From Buchanan to Cloverdale the going is fair and from Cloverdale to Roanoke, a matter of 8 miles, there is a splendid macadam road that winds dangerously around numerous hillocks into the city. While some of the Glidden cars made as high as 58 miles an hour in the terrific rainstorm over this particular stretch of road, the dangers of high speed, even in dry weather, will be very apparent to any tourist.

For 40 miles south from Roanoke, the roads are indescribable in wet weather. But if there has been a dry spell of a week or more the scenic grandeur in which they are set would repay the suffering they must cause to automobile tourists in passing over them.

Circling Mill Mountain, one of the show spots of the section, the road mounts a stiff grade through red clay for about 5 miles, where a heavy down grade is met. At the bottom of this grade is found the left fork of the Roanoke River, known locally as Back Creek. If there has been rain in the hills the night before, beware of Back Creek. It was here that nearly half of the Glidden Tour stalled impotently while the swirling water hummed merrily through the under-pinning of the cars after short-circuiting the magnetos. Such treatment is outrageous for as useful and valuable a bit of mechanism as an automobile and the effects of the flood were apparent in the Glidden caravan all the way to Jacksonville.



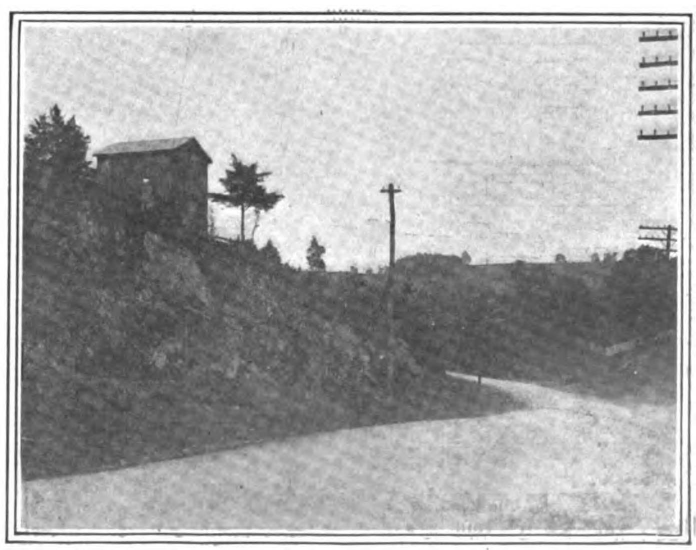
One of the few stretches of improved road near Lexington

After getting across this ford, which could be bridged permanently for a comparatively small sum, there is a steady climb for 5 miles through mountains that rival anything in the world for scenic effects.

The poorest country passed during the trip will be found immediately after reaching the summit. Houses are unpainted, children clothed in calico and without foot covering and a general air of unthrift and lack of purpose. The roads are unimproved and through the hills to Martinsville are a fierce trial to car and passengers. Fords and gullies follow one another in rapid succession and the impossibility of regular wagon traffic over the roads in their present condition was the most salient fact impressed upon the Glidden tourists in passing.

At Martinsville there is a considerable improvement and for the remainder of the 75 miles that lie between Roanoke and the North Carolina line the road grows better with the passage of each mile. There are a number of stiff grades but the fords in this section of the road have been bridged and there is ample evidence of more wealth, intelligence and industry than appears a little further north.

The road through Virginia is 276.3 miles long. At least 75 miles of this is unimproved and unfit for travel during wet weather. There are thirty-seven fords of various sizes ranging from that across Back Creek to small runs that barely wet the tires in passing. Besides these things it must be acknowledged that the pike through the Shenandoah Valley makes good riding in comparison with the rest of the trip.



Leaving Timber Ridge, the highway is excellent for a short distance

In the Making of a Radiator

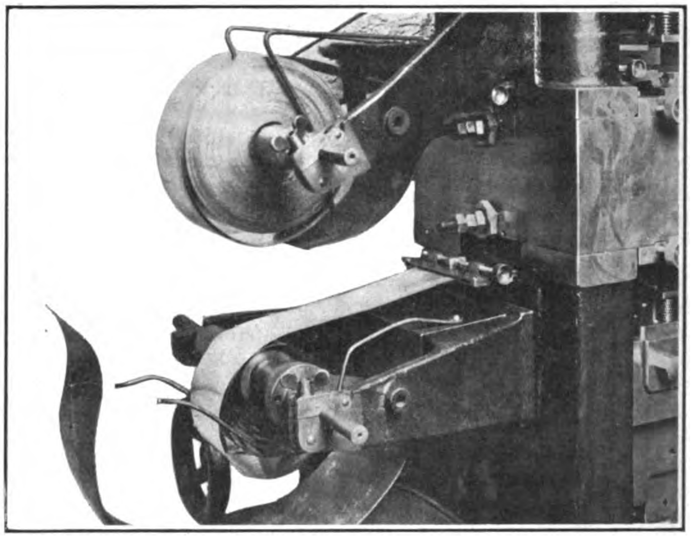
THE Livingston radiator is of the zigzag tube type. The water enters the top of the radiator, according to the usual custom, and passes through the various tubes until it reaches the bottom, whereupon it flows into the water outlet pipe and into the cooling water inlet of the engine. The shape of the tubes is peculiar and gives the water a very devious course as it flows on its way. Each tube is of the same width as the radiator and of such a shape that the water passes through a distance equal to double the length of the radiator from top to bottom. This is effected by the water having to pass alternately through a horizontal space of tubing equal in length to each vertical space through which it passes. The tube consists of a number of unclosed squares, the lower side of each forming the upper side of that next below it.

A series of these tubes placed alongside of one another gives the effect of a honeycomb. The air is drawn through the open spaces between the tubes and cools the water which passes through them.

Simplicity and speed feature the manufacture of this radiator. The raw material is transformed into the finished product by a series of operations which progress step by step with as little lost time or effort as could be possible in a process of manufacture which involves the various progressive steps toward the completion of the work.

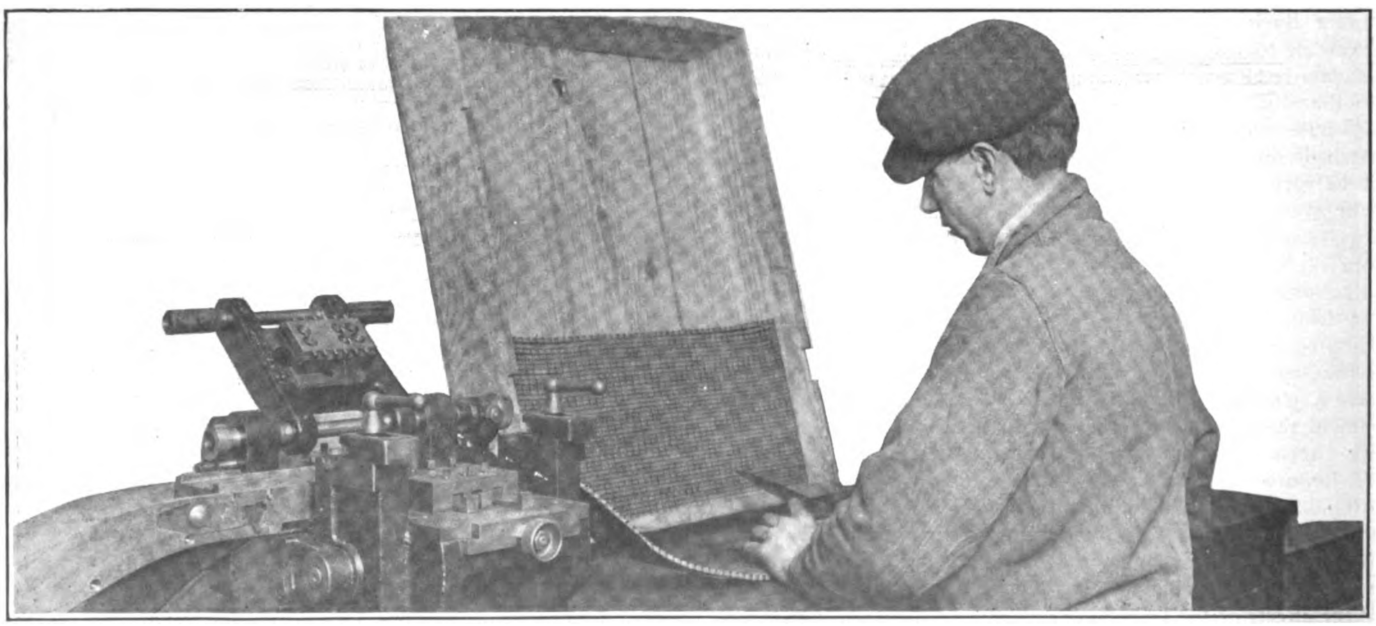
The bronze of which the radiators are made comes to the factory in rolls of different widths, which are used according to the purposes for which the radiator is required. The sheets of bronze are placed upon a spindle of a machine which is adapted to carry any size roll required. Below the spindle carrying the first roll there is a spindle which carries another roll of bronze which is slightly wider, for a purpose which will be seen later. The metal passes from the roll into the machine and is led through guides into a space in which there is a die.

As the metal is fed to the machine the die rises and falls, the die for the upper roll being entirely separate from that which operates the lower. The dies crimp the metal and corrugate the crimps, which are square in shape. After having passed the die the bronze is carried along in its corrugated form until it passes out of the first part of the machine into a guide which is so arranged as to bring the two strips together before they pass to the second series of operations, which is carried on by the same machine as contains the die. The strips having been brought together so that the upper and lower pieces fit into each other, with the square crimps in mesh, they are led into a block which contains the mechanism for firmly joining them together.

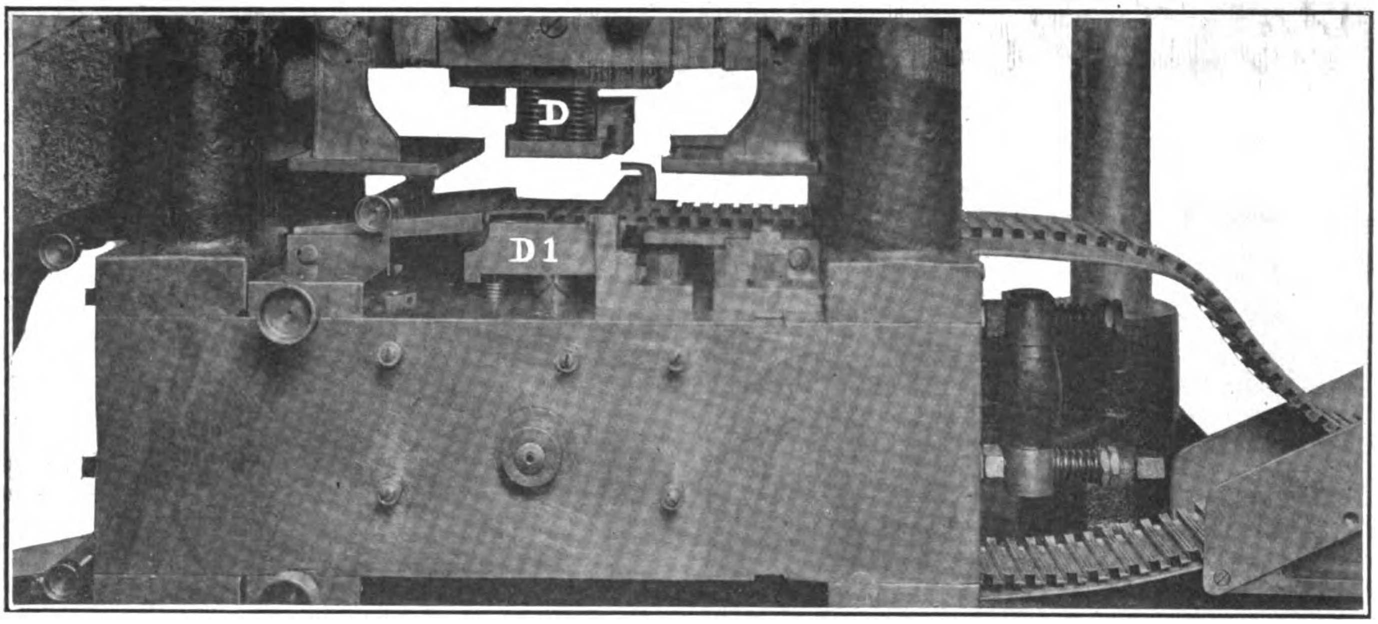


Stage 1—The raw material entering the crimping machine

As the lower strip passes into the reach of the tool it is cut at the ends so that a flange is formed. It is for the purpose of forming this flange that the lower strip is wider than the upper. The next operation bends the flange up slightly. The other tools then turn it over and clamp it tight. The corrugations in the base of each of the crimps are arranged so that they are opposite to each other, thus leaving an open space between them for the easy circulation of the water. The two strips when fastened together form one of the tubes of the radiator. Another purpose of the small corrugations is to aid in the easy expansion and contraction of the metal without fear of damage to the fastenings of the tubes or of the bursting of the metal itself.



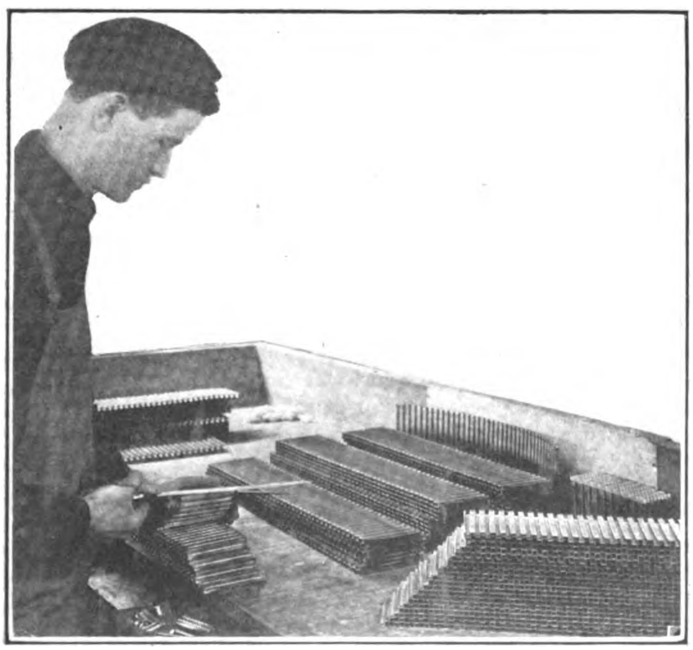
Stage 3—Cutting the clamped tubes to their proper length and placing them in a box of the correct width



Stage 2—The strips of metal passing through the corrugating and crimping dies. The strips flow together as shown

After having been crimped, corrugated and joined together the two strips pass on as one tube to the next operation, which is to cut them into lengths as required for the particular radiator which is being made. The length to which each tube is cut is equal to the extreme depth of the radiator from top to bottom; that is, the tubes are all cut to the same length as the longest tube in the radiator. A tube which has been cut off forms a guide for the length of those cut, so that after each length is cut off it can be placed in the box which is made for the purpose of holding them as they are cut off.

The boxes are so constructed that they are just wide enough for each radiator, and after they are filled there is enough tubing in them to make the radiator required. When the tubes are put in the box they are watched to determine any inaccuracies which may have accidentally found their way into the cutting or machine work. These inaccuracies will be very easily determined by a variation of the straight line which should be formed by placing the tubes upon each other in the box. After the boxes are filled the first series of operations is finished and they are transported from the machine room to the next stage in the work which consists in shaping the sections and soldering them.

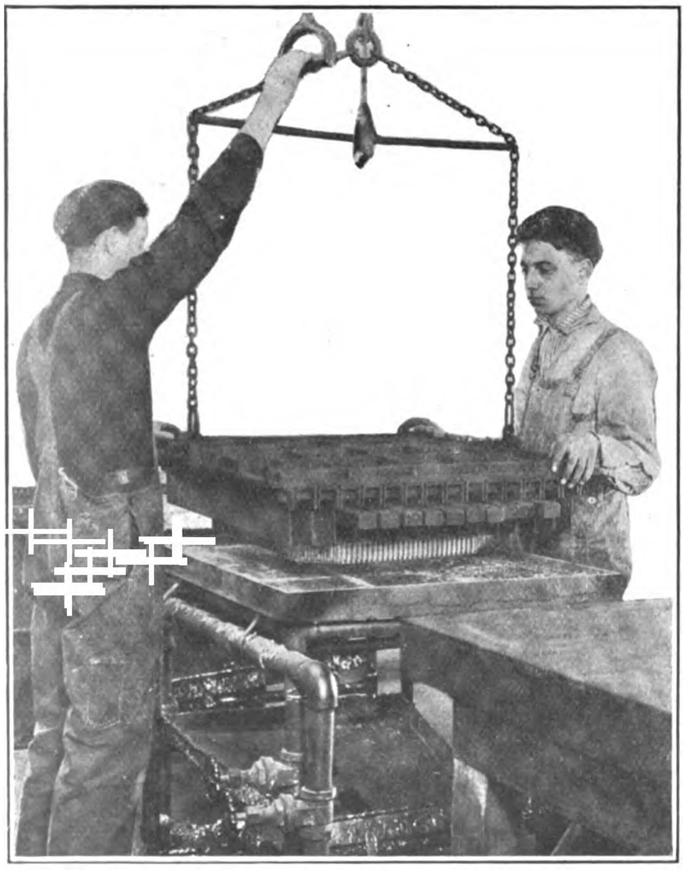


Stage 4—Cutting the tubes to conform to shape of frame

When the box with the set of tubes arrives at the bench at which the work of shaping the radiators is carried out, the tubes are removed one by one and compared with the frame into which they are to fit. This will give the proper length of each tube, and it is cut accordingly. After having carried out the operation of cutting the tubes for a given type of radiator shape for a short time, the operator becomes so familiar with his work that he will know whether there should be a variation of one or two squares in the length of the succeeding tubes in order to secure the required shape. In the case of a radiator which is square, such as is used occasionally on trucks, there will be no cutting required.

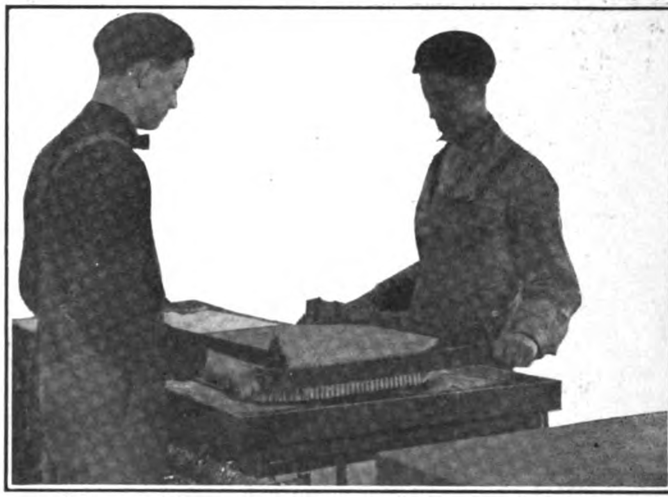
After having been cut to the proper form the tubes are placed as they are to go into the radiator frame and set up on a slab from which project a series of pins. The tubes are set upon the slab, being held in their exact relative positions by the pins. A strip of brass tapered much in the form of a knife blade is then called into use for the purpose of opening the ends of the pipes which may have been closed by being passed through the various stages of the work. The top and bottom of each tube will have to be opened in this manner so that the water will enter into all of them equally in passing from the top of the radiator to the bottom. A full use of all the cooling space available will not be had unless these ends are properly opened.

When the tubes have been set upon the slab correctly and the ends of the tubes opened the section is ready to be soldered together. In order to do this as expeditiously as possible the pin frame is attached to a small electric traveling crane which runs along a beam above the table upon which the frame rests while the sections are being placed upon the pins. A single chain hangs from the crane, carrying a hook which may be seen by referring to stage 5. This hook engages with the chain which holds the frame. The frame chain is spread apart by a brace so as not to interfere with the free operation of the crane. When the work of opening the ends of the various tubes is completed the frame is lifted above the table by the crane and two men run it along the table, the whole frame traveling very easily since the wheels of the crane run freely on the track. When the end of the table is reached the framework with its section pinned to it is seized and given a turn so as to bring the frame in a reversed position; that is, with the section of tubes hanging down from the frame, as seen



Stage 5—The cut tubes are placed in the frame F and held by pins P

Stage 6—Soldering the ends of the section to hold the tubes together



Stage 7—Dipping the other side of the section into the solder

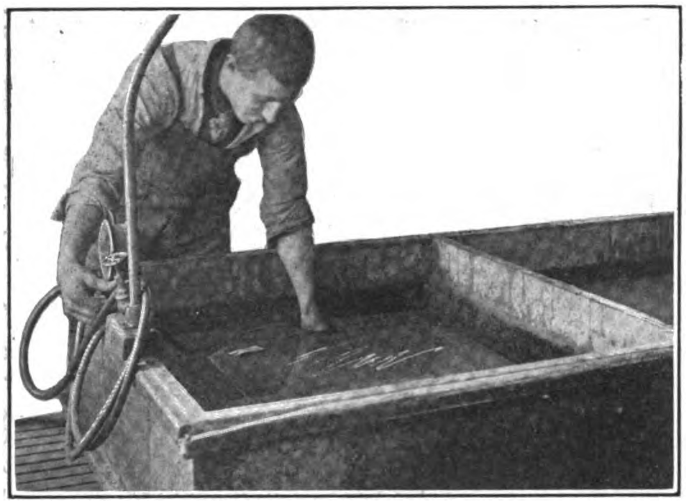
in stage 6. The crane is then run along the track again until it is brought above a trough of zinc chloride, when the frame is lowered so that the outer face of the section will be immersed in the liquid. After this has been accomplished the section is ready to be dipped in the solder, which operation is shown in stage 6. The solder is carried in a molten condition in the flat pan seen just below the inverted frame. The illustration depicts one of the men in the act of manipulating the crane so as to bring the frame gently into the solder, which is kept in a liquid state by means of a gas flame beneath the trough.

A cooling slab stands close to the soldering trough, and may be seen in stage 6. The section is lifted from the solder and placed upon the slab, which, owing to the qualities of the metal, quickly robs the solder of its heat and allows it to harden in a very short space of time. When the solder has become hard the section is lifted from the frame and is ready to be soldered on the reverse side. This operation is shown in stage 7, where the wooden frame into which the section is clamped for this second dipping may be seen. As may be noticed, this operation is exactly the same as the first dipping, except that instead of using the crane to carry the heavy framework it is done by hand, as the section has been removed from the frame and is held together by the solder accumulated on the first dipping.

The next operation consists of brazing a 3/8-inch strip of brass around the outer edges of the top and bottom of the tubes and at the same time running the solder well around the ends of the tubes. The solder used in this operation is string solder, which has been made by dipping a ladle into the trough containing the molten solder and pouring the solder on the cooling block. The ladle is arranged so that when tilted the solder will flow from five small holes about 1/2 inch apart. As the solder is poured the ladle is moved along horizontally so that when cooling the solder will have the appearance of a string. As the strips of solder cool they are pushed off the cooling slab into a basket and are used in this form, known as string solder.

After the strips are fastened and the tubes soldered tightly together the section is then turned over to the assembly department. The first process to which it is submitted here is one of cleaning. A scraper and file are employed to remove all the excess tin which may have accumulated during the various processes through which the product has passed from the time it was a piece of raw material. The section is mounted upon a bench, as is shown in stage 8, and filed clean on all sides. It will often be found that a bubble of solder will have formed across the face of one of the squares in the section. This is also removed during this stage of the work, along with all the other excess material.

The frame of the radiator has been in course of construction at the same time as the tubular sections. The sheet brass of which it is composed has been bent and cut to form and the ends soldered. Each make of car usually has some variation in the shape of the radiator, so that separate frame shapes



Stage 10—Giving the final test for leaks in the finished radiator

are made for each car. The frame is then ready to be assembled with the section. This is accomplished by placing the section upon a horse, as seen in stage 9, and laying the frame over it. Any irregularities in shape are corrected and the frame is then finally slipped over the section and soldered carefully into place. The string solder is used in this operation and, as the strips are very thin, it is comparatively easy to reach all points.

The frame and the section together compose the radiator. The first step taken with the assembled radiator is to test it for leaks or defects. This is done by placing the radiator in a tank, as shown in stage 10. A supply of compressed air is available for this purpose, and this is led into the radiator. The outlet is corked up so that no air can escape and a pressure of 20 pounds is put on the radiator. If there are any leaks the air will escape in bubbles and indicate the position to the observer, who can then readily solder it at the required point. After the tests have been made and any leaks sealed the radiator is ready for the finishing touches, which consist for the most part of polishing and buffing processes.

The finishing polish is put on by hand and the radiators are then stacked up ready for handling by the delivery department. The handling of the radiator from start to finish is made as simple as possible by having the plant so arranged that one stage can follow another with as little interval between them as possible. There are no long pauses for parts to dry before the radiator can be touched, and there are no long distances through which parts have to be moved in the different stages of construction. They are all on the same floor and so arranged that the work starts from one end and gradually progresses through the shop until it is completed at the most convenient point for handling the finished product.

Stage 9—Fitting the radiator frame to the section before soldering them together

Stage 8—Scraping the excess tin accumulated during the manufacture from the section before assembling

Motor Wagons for Military Use

Consul General John L. Griffiths, London, England, is responsible for the statement that the British War Office has furnished particulars of a provisional scheme for the subsidizing of petrol motor lorries or wagons built after January 1, 1910, and owned by civilians. The vehicles will only be purchased in event of national emergency and will not be enrolled for hire purpose or for maneuvers. The War Department is to have the right to purchase on fixed terms any enrolled vehicle when the War Minister certifies in writing under his hand that the country is in a state of national danger or if a proclamation be issued under the reserve forces act of 1882.

The lorries which may be thus acquired are divided into two classes, (1) those capable of carrying a useful load of 3 tons (ton = 2,240 pounds) at 10 miles an hour, and (2) those capable of carrying a useful load of 30 hundredweight (hundredweight = 112 pounds) at 12 miles an hour. The wagons will be subsidized for two years, and the owners will receive an initial subsidy varying from $39 to $58 and an annual subsidy of $73, payable half-yearly. A further $48 will be paid if the wagons carry a second magneto.

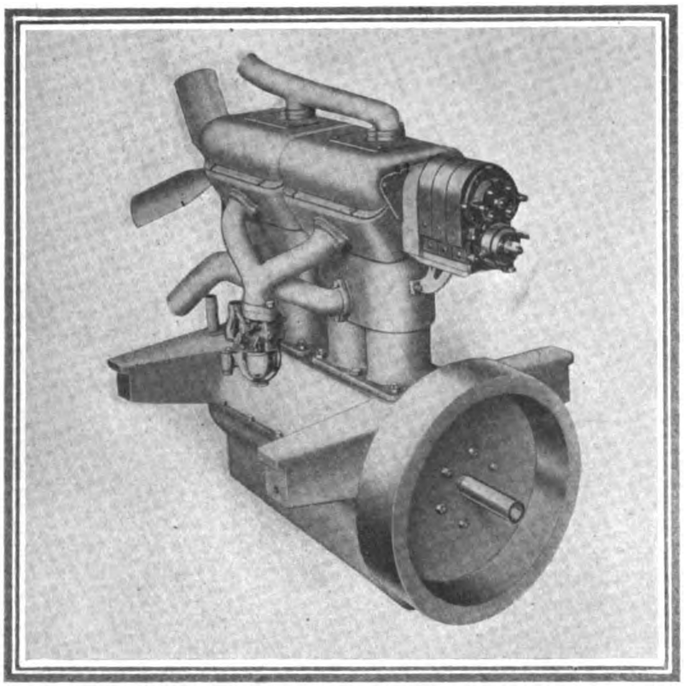


Fig. 1—External view of carbureter side of the R. C. Mitchell motor, showing simplicity of construction

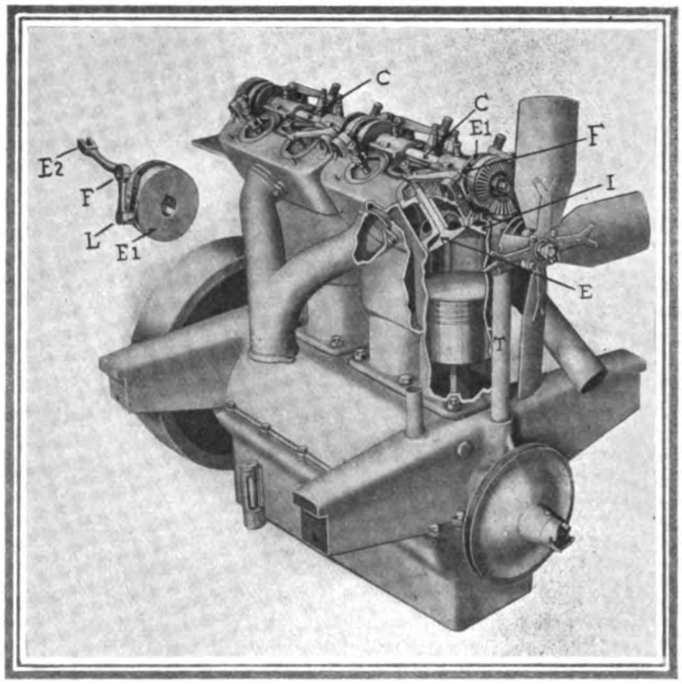

Fig. 2—Exhaust side of Mitchell motor, with part of casing removed to show the operation of the valves

Explaining the Mitchell Motor

AN inspection of the motor shown in Figs. 1 and 2 will reveal a number of new features contained in this construction of engine. The Mitchell motor is of the four-cylinder, four-cycle type, and is characterized by the small number of parts constituting it. Fig. 1, which is an external view of the carbureter side of the motor, shows that all the delicate parts of the engine have been given a high location, the valves for admission and exhaust being arranged in the heads of the cylinders and driven from above by a camshaft stationed above the cylinders. As is seen in Fig. 1, the magneto has also been given a high-up location, with the obvious advantage of it being free from troubles that arise in fording a stream. The importance of this feature was fully recognized by the participants of the recent Glidden tour.

The cylinders are of gray iron and cast in pairs, with ample water jackets surrounding those portions which require cooling. The water piping has been made of liberal dimensions, and the cooling water, which is circulated by a centrifugal pump in the crankcase, enters the jacket on the inlet side, leaving it, after having played around the cylinders, through the pipes seen on the top of the jacket. The valves are in cages in the cylinder heads, and referring to Fig. 2 it is seen that the mushrooms, E of the inlet and I of the exhaust, as they seat form an obtuse angle. The valves are of large diameter so as to permit of rapid charging and scavenging, and are actuated from the overhead camshaft C through barred cams E1. The end of the link L of the valve stem lever slides in the cam slot, and the enlarged view of the cam in Fig. 2 illustrates the construction of this member. The lever is fulcrumed at F, so that the eccentric action of E1 during the rotation of the camshaft causes the end E2 of the valve lever to be reciprocated, thereby lifting and dropping the mushroom off and to its seat. The location and construction of the cams does away with the necessity of using heavy springs with a consequent loss of power. The cams close the valves as positively as they open them at all motor speeds.

The camshaft itself is driven at half engine speed from the crankshaft by means of transmission rod T engaging crank and camshafts by means of bevel gears at both its ends; camshaft is equipped with wick oiling and reservoir containing enough lubricant to keep the shaft well oiled for a month. Each barrel cam operates one inlet and one exhaust valve, so that only four cams are required to operate the eight valves. The magneto is driven by a spur gear direct from the camshaft and at the same speed as this shaft. The location of the magneto keeps it beyond the range of dirt and grease, and the design of the motor is such that the magneto extends through the dash, being directly accessible for the driver if inspection is wanted.

As may be seen from Fig. 1, the carbureter and intake manifold are located at the left side of the motor, and the exhaust appliances are stationed on the other side of the engine. Beside the fact that this arrangement keeps the sides of the engine free of all accessories, save a sight-feed on the crankcase on the exhaust side, the peculiar arrangement of the magneto is accompanied by a saving in power required to drive it. The direct drive of the magneto off the camshaft does away with the friction loss otherwise encountered in the magneto half-time gear.

All working parts of the motors are fully encased, but the jacket is so bolted to the base chamber that eventual inspection may be had without difficulty. In the crankcase is located an oil pump, which lifts the oil from the base chamber, serving as a reservoir, to the cylinder bearings and connecting rods through small brass leads, affording a positive force-feed system.

The flywheel is of substantial dimension, with sufficient room in it to take in a clutch of the cone or disc type. It is located adjacent to the rear end of the crankcase casting, which has two pressed-steel drop arms on each side, permitting of suspending the motor on a chassis frame.

The initial motor constructed by the designer has 4 3-16 inches bore and a stroke of 5 inches. It is used on a seven-passenger touring car, and for nine months has given very satisfactory service. The inventor and designer of the motor is R. C. Mitchell, of Springfield, Ohio.

The Long-Stroke Motor for Cars

Part I.

By Professor W. D. Ennis.

Should Wear Longer Than the Short-Stroke Type and Prove a Better Hill-Climber—It Requires a Re-designing of the Motor and Generally Raises the Center of Gravity of the Car—Little Extra Weight Need Be Added—The Cooling Problem Is Not Disturbed—A Plea to Standardize the Revolutions per Minute of the Crankshaft, Rather Than the Piston Speed in Estimating the Horsepower of the Motor—Many Practical Considerations.

THE practice of rating motors at standardized piston speeds may be justly criticised. All common rating formulas assume some fixed speed of piston. Thus the expression,

$$HP = \frac{nd^2}{4}$$

for the horsepower output of n four-cycle cylinders having each a diameter of d inches holds approximately, only for a piston speed of 1000 feet per minute. By this rule an ordinary automobile motor with four cylinders of 4-inch diameter would give 16 horsepower, no matter what its stroke. The length of stroke is immaterial because with a fixed piston speed the longer the stroke the fewer the number of revolutions per minute. For example, with a 6-inch stroke we should run at 1000 revolutions per minute, and with a 4-inch stroke at 1500. In each case the piston speed is 1000 feet per minute.

Short stroke means high rotative or crankshaft speed for a given piston speed. Assume the useful mileage of a certain car to be 100,000 miles, during which the travel of a point on one of its 34-inch tires will be

$$12 \text{ inches} \times 100{,}000 \times 5280 = 6{,}336{,}000{,}000 \text{ inches}$$

Since the circumference of the tire is $34 \times 3.1416 = 106.5$ inches, the wheel will have made $6{,}336{,}000{,}000 \div 106.5 = 59{,}400{,}000$ revolutions during the life of the car. If the average gear ratio between motor and rear wheels during this whole period has been 4, the motor will have made $4 \times 59{,}400{,}000 = 237{,}600{,}000$ revolutions. If its stroke is 5 inches, its pistons will each have traveled

$$2 \times 5 \times 237{,}600{,}000 \times \frac{1}{12} = 198{,}000{,}000 \text{ feet}$$

or 37,550 miles. The same total piston travel would have been realized by a motor of 6-inch stroke while making 198,000,000 revolutions. For a given piston speed, or piston travel, the revolutions per minute of the motor will vary inversely as its stroke.

Standardized Revolutions Per Minute

It is the number of revolutions per minute that should be standardized, rather than the piston speed. Shocks wear out machinery. Every time a crankshaft makes a revolution, the piston reverses its direction of movement twice. In each cylinder of the 5-inch stroke motor just referred to, there will have been 475,200,000 such reversals and shocks. By changing the stroke to 6 inches, the mileage and horsepower might be the same, while the number of shocks would be reduced 20 per cent., the piston speed remaining constant. Roughly speaking, then, the 6-inch motor should be in better condition than the 5-inch, after 100,000 miles of service. When piston speeds were standardized, it was because stroke lengths were not greatly variable. With new length of stroke, new piston speeds are permissible, and the standard of piston speed will be directly related to the length of stroke.

The long stroke increases the horsepower capacity of the motor. Motor output is roughly proportional to piston speed. With a fixed number of revolutions per minute, the longer the stroke the higher the piston speed and the greater the power output.

Long-stroke motors have greater pulling power. This may be proved in two ways. First: Horsepower output is determined by pulling power for "tractive force" and speed, jointly. Consider two cars, moving at the same speed, up two parallel hills of different grades. One has a 5-inch motor, the other a 6-inch motor. Otherwise the cars are alike. The piston speeds being the same, the 6-inch motor will develop the greater horsepower by 20 per cent. This horsepower is exerted in propelling the car up the hill. The propelling or tractive force must be, then, 20 per cent. greater in the case of the 6-inch motor.

As a second proof, consider Fig. 1, which represents successive simplifications of the driving mechanism. In Part A the piston *B* moves in the cylinder *A*, its rod *C* being pinned to the gear *E* at *D*. This gear drives the larger gear *F* about the shaft *G*. The force exerted at the pin *D* by the rod turns the wheel *G* at rotative speed somewhat less than that of *E*. In Part B such force is represented by the arrow *L*, the wheel teeth are omitted, and the revolution of *J* on a roadway is assumed to be equivalent to the development of the traction or pulley force *K*. In Part C both wheels are shown on the same shaft. The ratio of their diameters must now be reversed in order that the peripheral or circumferential speed of the second wheel may be the same as in the first sketch. In Part D the wheels are replaced by the equivalent wheel spokes or levers *Q* and *R*. The length of *Q* is equal to half the diameter of the circle described by the pin *D* in Part A. The length of *R* is half the diameter of the large wheel *F*, and is independent of the stroke of the motor. This stroke is, however, equal to twice the length *Q*.

Then if a given force be developed by the explosion in the cylinder, regardless of length of stroke, we have, in Part D, *P* and *R* fixed, *Q* proportional to the motor stroke, and *S* depending on all three. By the principle of levers,

$$P \times Q = R \times S. \text{ Then } S = \frac{PQ}{R}$$

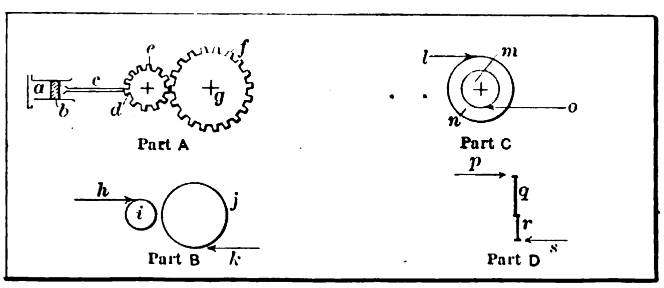

Fig. 1—Representing successive simplification of the driving mechanism of an automobile

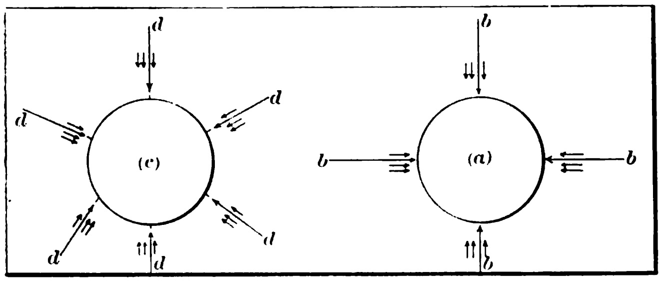

Fig. 2—Illustrating the comparative stresses in six-cylinder and four-cylinder motors

and is directly proportional to the stroke. And S is the tractive or pulling force exerted in propelling the car.

Increasing the number of cylinders does away with some of the advantages of the long-stroke motor. The total wear of the mechanism is dependent not only on the number of shocks but also on their intensity. At the moment when the piston is being reversed, at the head end of its power stroke, it undergoes the stress due to the pressure obtained in combustion. This pressure in pounds per square inch is independent of the length of the stroke. The total stress produced depends on the pressure and on the area of the piston. With six cylinders of the same aggregate piston area as four cylinders, the stresses in any one cylinder are only two-thirds as great as those in the four-cylinder motor. The condition of things is as suggested in Fig. 2. In the case of four cylinders, during two revolutions, each cylinder is fired once, giving the four severe stresses indicated by the arrows *B, B, B, B,* and reverses three times, giving the lighter stresses indicated by the short arrows. With six cylinders, there are six severe stresses and eighteen reversals, in two revolutions, but the former (indicated by the arrows *D, D, D, D, D, D*) are less severe than those with four cylinders of the same capacity. The possible number of revolutions during the life of the car will therefore be increased because the shocks of reversal are decreased in intensity: and in this respect the use of six cylinders serves the same purpose as the use of a long stroke.

Long-Stroke Motors Influence Design

The general use of long-stroke motors may seriously influence design standards. Fig. 3 shows that the over-all height of the motor includes the stroke, piston thickness and the clearance, which is proportional to the stroke, and the length of the connecting rod, also proportional to the stroke. If the connecting rod is twice the length of stroke, and the clearance height is half the stroke, then the head room necessary must exceed 3 1-2 times the length of the stroke, and a change of 2 inches in the latter will require 7 inches more head room. Obviously the overhead type of valve would with a motor of long stroke be undesirable. Again, the effect of increasing the stroke length may be to further increase the length of the connecting rod. Thus in Fig. 4, which is drawn to scale, we have a 4-inch piston, *A B*, with a stroke of 4 inches, *B C*, and 37 1-2 per cent. clearance, *C D*. Assume the connecting rod pin to be at *E* when the piston is down, and at *F* when the piston is up. If the clearance width of the rod is 1 inch, then the line *G*, drawn from *F* to just strike the inner bottom edge of the cylinder, represents the extreme of angularity of the connecting rod. If we place the shaft at the highest position possible, namely, at *J*, where the crank circle *H* (of diameter equal to the piston stroke) just strikes the rod pin *E*, we find that the most extreme swing of the connecting rod keeps within the clearance line *G*, and that the rod length may be as little as 4 inches, equal to the stroke. But in the 6-inch stroke motor, shown to the right, the same position for the shaft might be impracticable.

The long stroke means a new distribution of weights. If the shaft elevation is fixed, increasing the length of the stroke means a raising of the heavier parts of the usual type of motor, and unless some equivalent adjustment is made elsewhere in the opposite direction, the center of gravity of the whole car will be elevated. A higher center of gravity should not be contemplated if cars are to be safe under usual curve and speed conditions. In Fig. 5, if *B* is the center of gravity, and if *A B* represent the centrifugal force due to rounding the curve, which depends on the radius of the curve and the speed, and *B C* the weight of the car; then the line *B D* joining *B* with the intersection *D* of lines parallel to *A B* and *B C*, as shown, represents the resultant force acting on the car through its center of gravity. If this line *B D* passes outside the base of the car, the latter will overturn. As shown, the line in question strikes the ground at *E*, while the wheel rests on the ground at *F*, so that the machine is safe. But if the center of gravity were raised to *G*, then with the same weight and centrifugal force the direction of the resultant line *G I* shows that the car would be unstable. Power plant and body design may thus be seriously influenced by the adoption of the long stroke.

The details of cylinder design may be modified. At standardized piston speed both the amount of mixture supplied and the time available to supply it will depend upon the stroke, and the necessary valve areas will be unaltered. But if *rotative* speeds be standardized and piston speeds be made proportional to strokes, then the long-stroke motor will demand a more rapid supply of gas and all ports will be made larger. Since there are objections to increasing valve travel, either increased valve areas or multiplied valves will be necessary.

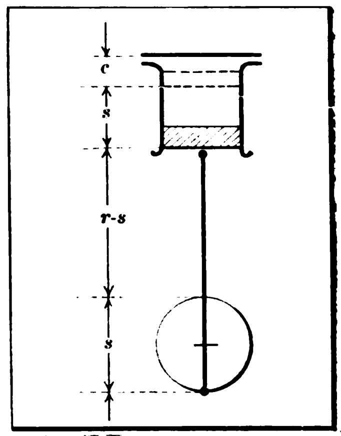

Fig. 3—Showing factors that must be considered in designing long-stroke motors

Cooling arrangements need not be greatly changed. The lengthening of the stroke gives a proportionate increase in power output. The amount of heat to be removed by water circulation will increase in about the same ratio as the power, and will therefore be directly proportional to the stroke. As the cylinder barrel length available for jacketing varies with the stroke, there is about the same amount of transmitting surface, considering the amount of heat to be carried off, in both types of cylinder. If the short stroke permits of overhead valves, however, the arrangement and effectiveness of jacketing may differ in the two motors.

The long-stroke cylinder affords, in proportion to its power capacity, more room for accessories on the side walls of the clearance space, and less room on the top, than the older type of motor. These available space conditions may easily lead to new standards in valve type, valve location and jacketing.

The reduction in friction and greater ease of lubrication sometimes claimed cannot yet be demonstrated. Following steam engine analogies, it is safe to say that in both of these important respects a slow running engine of long stroke surpasses one of short stroke and high speed. But in automobile practice, long strokes are apt to be associated with high speeds, the greater power output for a given size and weight being the main object in view: and if no greater expense in lost work by friction or cost of lubrication ensues, we shall still have ample ground for approving the novelty.

A similar consideration applies to the question of weights. A long-stroke motor weighs more because it is longer. But it gives more power. At equal rotative speeds, the long-stroke motor should weigh less, in proportion to its power output, than the one of short stroke. If comparisons of actual design, weights and rating fail to confirm this, it is because the long-stroke cylinders have not yet been rated at full piston speed. A speed of 1500 feet per minute is just as reasonable at 9-inch stroke as one of 1,000 feet per minute is at 6-inch stroke.

Relative weights of reciprocating parts are in favor of long strokes. The total pressures at reversal, represented by the arrows of Fig. 2, are less with long strokes, because piston diameters and areas are less for the same power. These total pressures determine dimensions of piston, rod, crank pin, crank and shaft.

Summary of the Results

Two schools of design are possible: With one present piston speeds may be regarded as the limit. Then the long-stroke motor will decrease the revolutions per minute, produce smoothness of running and lead to fewer breakdowns and longer life of plant. The power capacity will not be much increased, but the pulling force will be, and the cars will be able to negotiate steeper hills, though at low speeds. Valve areas will not necessarily increase. The motor weight will probably constitute an increased proportion of the whole weight of machine. Should the six-cylinder car prove especially more durable and smooth running than the four, then the long-stroke motor is not likely to monopolize the field with those who adhere to present piston speeds.

The other school of design standardizes rotative speeds. Long strokes then increase piston speeds and power output, while leading to about the same smoothness of running and length of life as in older designs. The pulling force will be no greater than that at lower piston speeds, but will be greater than in short stroke motors, regardless of piston speed. Large valve ports and passages will be necessary.

In either development, the long stroke properly applied necessitates re-designing throughout, particularly in order that the necessary head room may be obtained while keeping the center of gravity low. Valves will be kept at the sides of the cylinders rather than placed on top, and the type of valve used may be a modification from any now existing. Corresponding modifications in cooling arrangements will be necessary.

Reducing Time in Fire Fighting

For years the officials in charge of the fire departments of the large cities have been struggling with the problem of saving seconds. Everything possible toward that end has been done, the cost being given but little, if any, consideration. The wisdom of this course is apparent, the smallest fraction of time saved in the early stages of a fire being sufficient often to give the firemen that advantage which will prevent a small fire developing into a conflagration. Under the circumstances it is not to be wondered at that fire department officials of every city of considerable size are studying the possibilities of motor-driven apparatus, for in the single item of time saved the advantage of this latter-day method over the old horse-drawn proposition is almost beyond calculation. It is an actual fact, based upon figures gathered by officials of those cities which are fortunate enough to possess motor fire apparatus, that the time necessary to get to work at a fire has been reduced by more than one-half. This remarkable showing has attracted the attention of fire-fighters generally and is responsible in large measure for the demand from all sides for the early substitution of motor-driven apparatus for the antiquated horse-drawn machines, in the belief that the initial cost of installation of the former would be but a bagatelle when compared with the reduction of the annual fire losses following upon such a change.

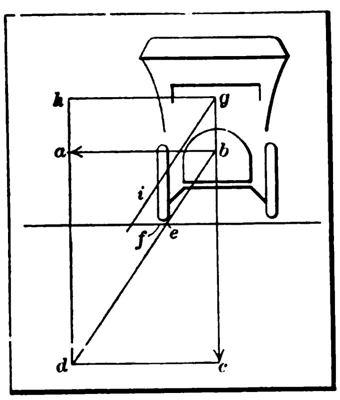

Fig. 5—Showing how length of the stroke raises the center of gravity of a car

Statistics of Italian Production

The value of the automobiles and automobile accessories exported from Turin, Italy, to the United States during 1910 was $295,013, as against $674,666 in 1909. Probably the year 1910 will hereafter appear as having marked a turn of the tide, and that European automobiles will in the future, on account of the formidable and increasing competition that they have met and must continue to meet from American automobile manufacturers, be exported to the United States in steadily decreasing numbers. The decrease can be explained in no other satisfactory way. It occurred in a year when the production of automobiles in the district of Turin and in Italy in general proved greater than ever before; when conditions in the district and throughout Italy were especially favorable to automobile builders; and when, for the first time, American automobiles and accessories entered Italian markets under markedly favorable conditions. The fact that the most important automobile-building company in Turin and Italy, and one of the most important in Europe, opened large works in the United States during the year had nothing to do with the decrease.

An estimate covering automobiles built in Turin during 1910 sets the number at 3,907, as against the estimate of 3,700 for 1909, and it is estimated that during 1910 only 560 automobiles were built in Italy outside of Piedmont.

Market conditions, on the whole, were good, and the demand for Turin automobiles, especially for cars of medium power, was satisfactory and uniform.

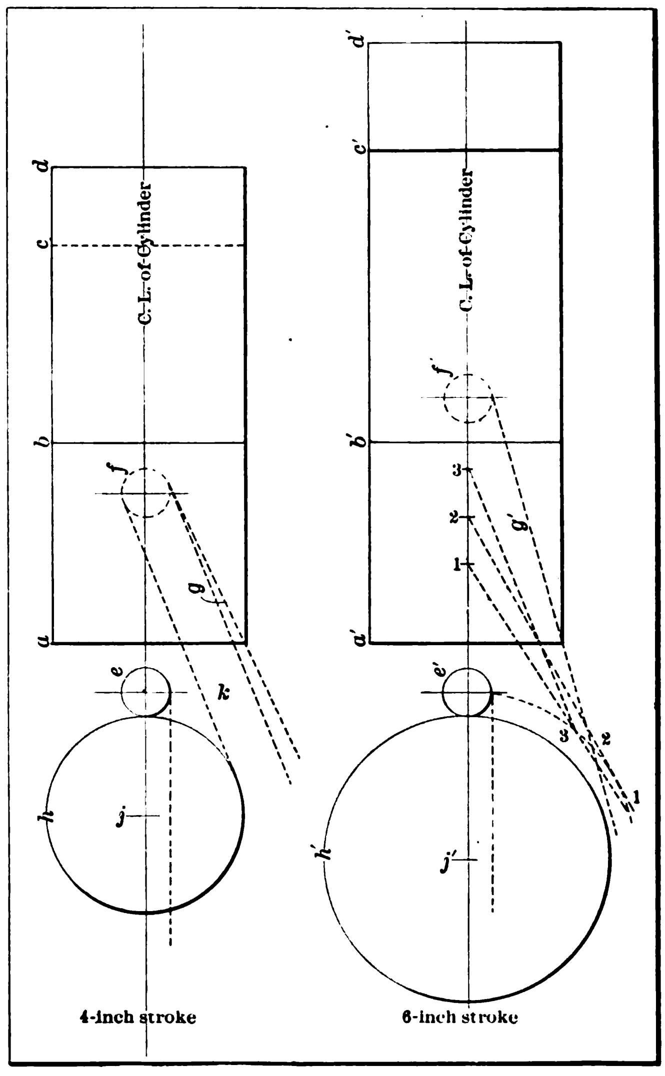

Fig. 4—Showing the clearance of connecting rods necessary in cylinders of different lengths

Digest of the Leading Foreign Papers

FEATURES OF RUTHARDT MAGNETO—The Ruthardt magneto represents a comparatively recent German reconstruction and rearrangement of the mechanical elements of the high-tension magneto, resulting in a considerable weight reduction, which is of special interest to aviators, but involving at the same time the introduction of features which are considered as technical improvements relating to efficiency and reliability. The magnet is composed of a certain number of magnetic discs of the shape shown in Fig. 1. The armature turns directly between the poles, so that pole pieces are avoided as well as the screws needed for fastening them. The poles are polished so as to further reduce the space between them and the armature, and the magnetic field is thus utilized to the full. The armature is of the Siemens T type with two bobbins, one primary and one secondary, completely insulated from one another. The interrupter, Fig. 2, has no bearings and consequently requires no oil; wearing parts are avoided in it. The receiver consists of an insulated block D secured to the rotating disc of the breaker box by a screw I. A bent leaf spring A, provided with a platinum contact B, is secured to a boss K forming part of the mass. Screw C with a platinum point is adjustable in block D, and one of the edges, L, of the latter serves as a runway for the fiber roller E, which can turn, with considerable play, around the small spindle F, while retained laterally by a flat spring, not shown. The free end of spring A is bent back somewhat and rests against the roller with a tendency to press it outward, in which thrust it is aided by the centrifugality of the parts. The roller which travels on the interior cylindrical surface of rim N will therefore admit contact of B and C—short-circuiting the armature—except while it passes over the cam G on rim N, when the roller is pushed inward and forces the spring A outward and the platinum points apart. Two cams are provided on rim N if the magneto is used for a two, four or six-cylinder engine. The breaker box is adjustable around the armature shaft, so that the normal timing of the ignition may be varied. The screw bolt with hexagon head M which holds the box to the armature shaft conducts also the primary current to block D. A leaf spring, not shown in the drawing, impinges upon the head of M and its other extremity terminates in a threaded wire to which is screwed the binding post connecting with the interrupter mechanism.

An accessory of the Ruthardt magneto which may be applied to other magnetos as well is the device adopted for the automatic advancement of the spark, with increasing motor speed. It consists simply in a coupling collar formed of two metallic plates, Fig. 3, in which there are formed a number of depressions serving as beds for an equal number of steel balls and so curved that the balls under the effect of centrifugality will tend to roll from the central portion of each depression to the portion which is nearer the periphery and more advanced in the direction of rotation. As the balls constitute the means by which rotation is transmitted from the driving plate to the driven plate in this coupling, it is understood that the driven plate is advanced in its relation to the driving plate when the balls take this more peripheral, and more advanced, position, and, as the driven plate is coupled to the armature shaft and the driving plate to the motor, it is seen that the object of advancing the spark by a device which forms no part of the magneto itself is accomplished. The description does not state by what means the two plates of the coupling are held in such a relation that the balls in seeking more peripheral positions are forced to overcome a small resistance, unvarying in amount.

The weight of the Ruthardt magneto is given as about 12 pounds for a 25-horsepower, 4-cylinder motor, reducible to 2 1-2 pounds in the type intended for a 4-horsepower motor bicycle.—From description by F. Carles in *La Vie Automobile*, August 5.

---

GERMAN CONSTRUCTION—From observations of a general character on the trend of innovations in German automobiles, as these were shown at the recent international automobile exhibition in Berlin, it appears that great simplicity in lines and colors marks practically all automobiles intended for private use, but that, on the other hand, the public cabs exhibit schemes of decoration by which the builders have apparently aimed to meet the supposed vulgarian taste of the masses. Many of them look like movable feasts. Festoons of roses and violets or vines heavy with enormous bunches of full-ripe grapes wind themselves in painted counterfeit around the carriage work, and even encircle the driver's seat, and gold and silver plating in profusion seems to belie the statement that power cabs can be made to pay only by the strictest economy. The use of art etching on the window panes seems particularly superfluous in view of the fact that, whenever a window is broken by a "fare," there is invariably a quarrel about the amount of the damage to be paid.

Technically, it is noticed that in nearly all of the German automobiles at the exhibition the designers have gone to great lengths to reduce all noises to a minimum. Especially the valve movements have been the object of attention, and this is ascribed largely to the influence of the valveless motors and their success. In one of the Adler motors a cylindrical heel on the mushroom valve admits the use of cams which rise almost imperceptibly from their base circle, while in other cases the noise is not really removed but only muffled and localized by encasing the valve springs.

The oil ducts and force-feed oilers are now uniformly enclosed within the crankshaft casing, and the ducts to the individual bearings are frequently worked out as canalizations in the motor castings. As the perfecting of the oil feed has a considerable influence on the exhaust and on the formation of carbon deposits in the combustion chambers and in the grooves of the piston rings, many attempts have been made to so regulate the oil feed that surplus oil will escape combustion in the greatest possible degree, particularly under those trying circumstances when cars are forced to many stops or half-stops in close traffic and are likely to omit noxious odors in the exhaust.

Radiators are uniformly smaller than formerly, but much has been done to increase the air-cooling of the water-cooling system. Motors entirely cooled by air have, on the other hand, completely disappeared, even in the smallest cars.

The carbureters show a revolution. The noiseless double-jet type with auxiliary air inlet holds the field.

The magnetos, while reduced in size, develop strong sparks even at low rotary velocity of the shaft, so that starting of the vehicles has become much facilitated.

The valveless motor is represented not only by the Daimler companies of Stuttgart and Unterturckheim, but also by Loeb & Company, of Charlottenburg, and Stoewer Brothers, of Stettin.—From *Automobil-Betrieb*, October 1 and 15.

THE WIRE MESH WINDSHIELD—Trials have been made lately on the Brooklands track in England of windshields in which the customary glass surface is replaced by wire screening. Lightness, durability, low cost and safety in case of accident are not the only virtues claimed. They are supposed to afford better protection, on the following theory: The solid glass front constitutes an impenetrable barrier to the wind, and there is therefore formed a low-pressure atmospheric center behind it, causing the air to rush in from the sides in a disagreeably turbulent fashion. The wire screening, on the contrary, lets the air through while yet tempering its force, so that it does not strike the faces of the automobilists unpleasantly. When it rains the water sticks to the glass and bars the outlook, while it is driven through the wire web or runs down, finding but slight basis for adhesion in the thin strands.

Further information brings out, however, that wire screening was tried long ago for this purpose by Mr. Ferra, director of the astronomical observatory of French Indo-China. He found it good enough against wind and dust, but impracticable in a driving rain. The water stayed in the meshes and it was difficult to see through. Mr. Ferra's screening was quite close, the additional informant concedes, leaving openings which were only 1-2 millimeter square, and the possibility remains that the English improvement involves somewhat larger meshes and perhaps the use of a metal, for the wires, to which the water has a minimum of adhesion.—From *Automobil-Betrieb*, October 1 and 15.

RULES FOR THE PRESERVATION OF METALLIC MACHINE PARTS against rust were discussed and formulated with much detail at the last congress at Zurich by the International Association for the Testing of Materials. An elaborate report of the subject was prepared. The principal qualities which coatings for metallic pieces should possess are the following:

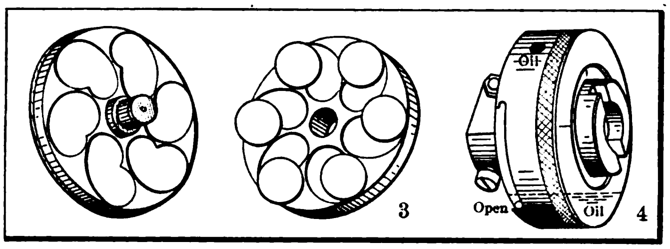

Fig. 3—Coupling plates with steel balls. Fig. 4—The complete coupling between armature shaft and motor, allowing automatic advancement of ignition by magneto

The coat should be thick; to this end the paint must contain as little as possible of volatile substances, excluding by this rule those having a turpentine base and colors derived from coal tar.

The coat must be at once elastic and hard, so as to resist well in the case of expansions and contractions and also against shocks and vibrations. These two conditions lead to products of a linseed oil base, which when dried form a soft elastic skin which in itself hardens very slowly but can be hardened by the admixture of metallic oxides.

The coat finally must be and remain continuous without shrinkage and cracking, which means that the paint must not be subject to decomposition.

The conclusions of the committee in charge of the subject are very precise. The colors to be used should be formed from sesquioxides of iron emulated in boiled linseed oil. The boiling of the oil should include a certain quantity of litharge or peroxide of manganese, giving a product of a minimum density of 0.93.

White or red lead or even graphite, if reduced to an impalpable powder, may be substituted for the iron oxide. These powders however must be in a state of purity and absolutely free from sulphur.—From *Le Génie Rural*, No. 37 (Sept.).

A VIGOROUS IGNITION always has a tendency to reduce the fuel consumption and to facilitate starting of the motor; therefore, it is often difficult to distinguish between an error relating to the adjustment of the carbureter and one relating to weakness or faulty timing of the spark.

Harking Back a Decade

ITEMS appearing in the issue of *The Motor Review* under date of November 7, 1901:

The second annual automobile show being held this week at Madison Square Garden is easily the largest and most important event of its kind ever held in this country. Among the exhibitors are thirty-nine American manufacturing concerns, showing fifty-five gasoline cars; fifty-eight steamers and twenty-four electrics. Twenty different varieties of gasoline cars are on exhibition. Opening night drew an immense crowd of well-dressed automobile enthusiasts.

Great progress is to be noted in the development of the gasoline cars. The motors are still unstandardized and both single and double cylinders have their advocates while the question of upright or horizontal position for the cylinders is still a live issue. Tonneaus are to be seen on all kinds of cars and front end motor bonnets are quite common. Surface carbureters have lost favor. The magneto generator is coming into more general use. Transmission gears now have three forward speeds. A majority of the models shown are chain-driven but bevel gear drives are gradually creeping into use. Running gears are generally heavier.

The Winton Motor Carriage Company has announced an increase of its capitalization from $200,000 to $1,000,000, to be used in extending its manufacturing facilities.

Apperson Brothers have withdrawn from the Haynes-Apperson Company and have formed a new company to manufacture cars at Kokomo, Ind. The parent company made twelve cars in 1898 and since has largely increased its production.

The H. H. Franklin Manufacturing Company, of Syracuse, N. Y., will increase its capitalization from $100,000 to $250,000 and will manufacture a gasoline automobile which is said to contain several unusual features.

Exports of automobiles and automobile parts in September amounted to $78,100, an increase in excess of $22,000 over the figures for August. England took merchandise of this character valued at $56,000.

Opinions are likely to differ as to the value of races and other exceptional public performances in advancing the motor vehicle in popular favor, but the attainment of high speed by some exceptional carriage is at best a doubtful benefit to the cause, especially when compared with some small improvement that tends to increase the utility or endurance of the vehicle.—*Editorial.*

R. M. Owen and four of his associates have incorporated the Western Automobile Company of Cleveland.

Emancipation Day will be celebrated in England next week to mark the fifth anniversary of the passage of a law allowing a speed of 12 miles an hour for automobiles.

Letters Answered and Discussed

Flow of Oil Must Be Watched

EDITOR THE AUTOMOBILE:

[2,900]—Please give advice on following subject. In filling crankcase of my automobile, which has splash system of oiling, I always spill some lubricant over outside of casting and often also my clothes. How can I get away from this abuse? JOHN F. MURRAY.

Corsicana Junction, Tex.

A simple way of avoiding a dirty job is shown in Fig. 1. The upper half of the basechamber is shown, which has been tapped and a flanged filler attached to it. Flange and casting surface must be kept in tight relation by means of a gasket. At a somewhat lower point than the filler, the casting is tapped for a 1-inch pipe and an elbow is screwed into the opening, with the other arm standing erect. Into this arm is fitted a sight-feed, as shown in the illustration. If filler and sight-feed are well fitted, they communicate through the crankcase, and the level of the oil in the basechamber will be able to be read clearly on the sight-feed.

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

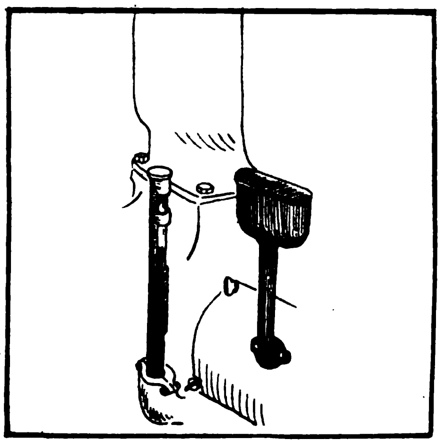

Fig. 1—Method of attaching a sight-feed and filler to the base chamber of a motor

Acetylene Must Be Clean

Editor THE AUTOMOBILE:

[2,901]—My acetylene lighting system, which has always been in good working order, has failed to give satisfaction of late. My generator consumes much more carbide than it used to, and instead of improving the light derived from this source I find that the good qualities of the acetylene are being lost. The headlights burn with a comparatively dim flame and the glass of the lens rapidly covers up with water drops. Can you suggest remedy? INTERESTED.

Darien, Ga.

Impurities are the cause of your trouble. To radically cure the ill, it will first be necessary to clean the generator of the residues left in there of the old carbide charges. It's a ten-to-one shot that you have plenty of ashes in the generator, but this is a very poor state of things. Cleaning the generator will do away with most of the impurities, but those which spring from inferior carbide must still be considered. Acetylene produced from poor carbide frequently carries foreign matter with it, as well as vapor, which of course deprives the flame of its fine lighting quality. These two troubles may be obviated by interposing a trap in the gas line near the generator. As Fig. 3 shows, the pipes leading to the headlights pass through a vessel containing a trapping chamber, in which the vapor or water drops traveling with the acetylene are precipitated. The draincock attached to the trap permits of emptying it when this becomes necessary. Another way of cleaning the acetylene on its way to the lights is to pass it through a vessel filled with moist sawdust or coke. A very clean gas will be obtained by this method of purifying it.

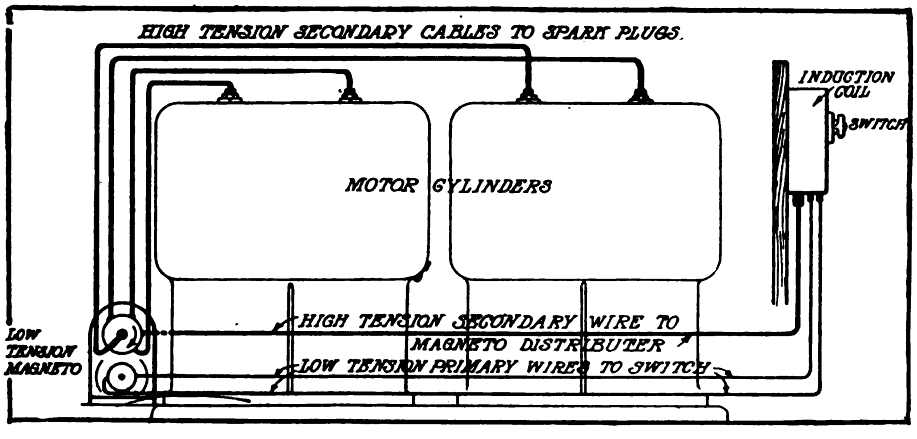

Fig. 2—Wiring system for ignition on a four-cylinder motor, using a low-tension magneto and an auxiliary coil

Wants Jump Spark Ignition

Editor THE AUTOMOBILE:

[2,902]—Please give me some information as to the installation of a jump spark ignition system using a low-tension magneto and an auxiliary coil on the dash. I have had considerable trouble with the system which I am now using and am thinking of changing. Any help which you can give me will be appreciated. C. J. D.

New York City.

The system of ignition which you mention is comparatively easy to install. Fig. 2 shows the method of wiring your car for it. The high tension secondary wires go to the spark plugs and one wire goes to the magneto distributor on the dash as shown. The primary wires are run directly to the switch. Care should be taken to make good contacts and to trace all connections after being made. If you are not familiar with this line of work, we would suggest that you have the job done by an experienced repair man.

Valve Spring Casings

Editor THE AUTOMOBILE:

[2,903]—Will you kindly illustrate in your columns some method of enclosing valve springs so as to keep out dirt?

Allentown, Pa. M. E. F.

One method of putting casings over valve springs is shown roughly by Fig. 4. However, this would apply only to valves which are in the cylinder heads. With the ordinary valve arrangement, casings, when used, are merely sleeves which are slipped over the valve springs and which rest on the spring seats. The casings here shown are bolted to the jacket heads and make a very tight and rigid construction. The use of these casings is becoming more and more general each year.

Mechanical Oiler Adjustment

Editor THE AUTOMOBILE:

[2,904]—Will you kindly give me the following information? I have a splash system of lubrication installed on my automobile, but from what I hear I believe that force-feed systems are positively superior to that

means of oiling. Therefore I would like to install a mechanical oiler on my car, especially since I understand that it is possible to regulate the amount of lubricant afforded to the various parts by this system. Will you explain in which way the flow of oil is lubricated? CONSTANT READER.

Bayonne, N. J.

There is usually some means of adjusting the length of the stroke of each plunger which forces oil out to its own particular part to be oiled, or of allowing a portion of the oil to flow back into the oil reservoir of the lubricator. Some have a sight-feed, other visible outlets to be used only temporarily during adjustment and wasting of the oil, so that they can be set for the required amount of oil for each movement of the pump plunger or other device for forcing the oil out. Start the engine and adjust for the required amount of oil. The feed device for each pipe should continue delivering the same amount of oil per stroke of its plunger or other device, whether the oil is thick or thin, hot or cold.

Carbureter Pops Once More

Editor THE AUTOMOBILE:

[2,905]—I have observed that when I speed up my engine the carbureter infallibly begins to pop. Why is this? Also, how can this nuisance be done away with?

Newark, N. J. S. M. G.

Popping in the carbureter, i. e., backfiring through the inlet pipe, may be due to a number of causes. A lean mixture may be the reason; in which case the engine should be given more gasoline, unless there is a leak in the inlet pipe or manifold, through which air is drawn and added to the mixture. An overheated cylinder or carbon deposits in the combustion chamber may cause preignition, permitting the flame to travel through open admission valve toward the carbureter. It may also be the fault of a weak inlet valve spring not strong enough to close the valve in time before the spark occurs in the cylinder; finally, a bent of dirty valve stem may be the cause of the evil. Remedies for all the troubles named are obvious.

Misfiring Due to Several Causes

Editor THE AUTOMOBILE:

[2,906]—The cylinders on my car misfired not infrequently during the last week or so, and in order to locate the trouble I have looked over the spark plugs, but they seem to be in good shape. I am sure something is wrong, but I understand very little of the jump-spark system that is used on my car. The system includes a battery and trembler spark coil for each cylinder. Will you explain the situation to a

Louisville, Ky. SUBSCRIBER.

Tests in the following order can be made until the trouble is found:

Switch on the reserve battery while still running.

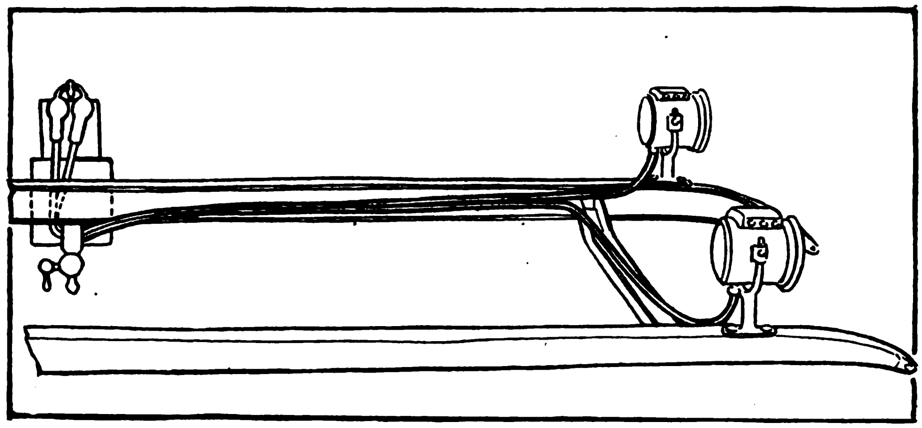

Fig. 3—How a trap may be interposed in the acetylene gas lead in order to catch water and mechanical impurities

Hold down the tremblers on the induction coils one at a time, or in pairs, to determine which cylinder misfires.

Stop the engine and crank slowly, noting whether each trembler vibrates strongly. If all vibrate weakly look for loose connections in the battery, the ground wires and the wire connecting the battery to the induction coil. Also examine for a broken wire inside the insulation of the same wires. Look for bare places on the wire between the battery and coils. See that the covering of the battery cells is not wet or worn off so that the zincs touch each other. Put in new low-tension wires.

If only one vibrator has weak action, clean the contact points, readjust its tension and examine the wire and connections between it and the timer. Examine the timer, noting whether the contacts and spring for the weak trembler are in order.

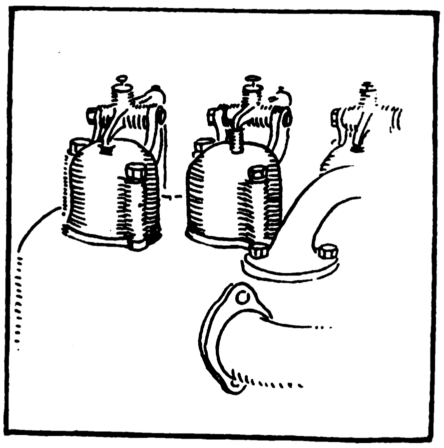

Fig. 4—Casings placed over the valve springs are efficacious in protecting them

If all tremblers vibrate strongly:

Remove the wire from the spark plug, hold its end about 1-4 inch from the engine casting, and close the circuit for that plug at the timer by turning the engine crank or placing a piece of metal so as to connect the timer terminal for that plug to the frame of the engine. The spark should jump the 1-4 inch gap. If not, look for poor insulation on the secondary wire.

If the spark coil has a visible safety spark gap, sparking at this point, when the wire is disconnected from the corresponding plug and held well away from the metal of the car, will indicate that the spark coil is in good condition. The primary circuit must of course be closed.

Remove the spark plug, connect its wire to it, lay the bushing of the plug against the engine and close the primary circuit corresponding to the plug under test. Notice whether the spark is strong between the plug points. If not, clean the plug or replace it with another. Even though the spark is strong when the plug is removed from the cylinder, the current may pass through mica insulation or dirt and grease on the insulating material when the plug is in the engine, owing to the higher resistance of the spark gap in the compressed mixture.

Put in a new spark plug.

Interchange the high-tension wires. The misfiring will occur at the plug to which the defective wire is connected.

See also compression test, sticky valve stem, carbureter troubles, timer troubles, defective spark coil, etc.

Old Clutch Comes Up

Editor THE AUTOMOBILE:

[2,907]—My clutch used to behave all right, but something seems to be at fault now. It is of the leather-faced cone type, and when I let it in gradually it suddenly seizes when a certain point has been reached. What is the matter? L. SMITH.

Stroudsburg, Pa.

Upon inspecting your clutch you will probably find the surface very dry. Put an ounce or two of castor or neat's foot oil on the cone, and distribute it carefully over the leather. This may be done by allowing one part of the clutch to slip over the other, then fastening the clutch open and thus letting it stand for about twelve hours. If the leather gets very oily some fuller's earth or chalk should be applied; it must be put on the clutch to absorb the surplus of oil. Sometimes it proves to be of advantage to clean the leather with gasoline before applying oil and chalk.

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

FULL SUPPLY OF TONGS REQUIRED—If the shop is to be equipped with a forge one of the requisites is a full set of tongs. The greatest point to remember in purchasing tongs is to have the handles of sufficient length from the pivot that there will be a good leverage in gripping a heavy article and that at the same time they will spring together close enough that the hand may grasp the ends of the tongs at the same time.

The tongs are made of various shapes, as seen in Fig. 1, so that they are adapted to the lifting of articles of different shapes and sizes. There are a number of uses to which these tongs may be put in governing the metal while it is in the fire, such as turning it over, raking the fire itself and performing the various little operations which will be found necessary in heating the work to the required temperature.

While at first sight it would seem that a full outfit of these tongs would be far from necessary, this is not the case if work is to be carried out on an extensive scale, for it is obviously impossible to pick up and throw a rivet with the same tool that is best in governing a piece of sheet metal. The uses of the other tools will suggest themselves by an examination of their shape.

The usefulness of these instruments, as of most other things about a shop, depends to a large extent upon the way in which they are kept. By this is meant not so much the deterioration of the metal as the arrangement of the tools themselves, although the upkeep of the instruments is a matter which will require some attention. The tongs should be placed in racks or suspended close to the forge, and in a light place, so that they may be readily seen. That is to say, they should be kept on the same side of the fire as that on which the operator stands while working, for it will be noticed that it is nearly impossible to see across a fire with any clearness. If they are placed in a rack they should be so arranged that they may be removed without great delay, as circumstances may arise that will demand hasty action on the part of the man who is performing the work.

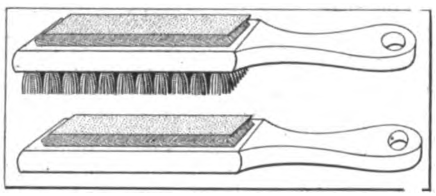

Fig. 2—File card and brush for cleaning files are truly necessary

The ends of the tongs will have to be occasionally cleaned so that the gripping qualities will not be impaired by the scale which forms on the parts subjected to the intense heat of the flames. This cleaning is done by means of files after the metal is cool. The filed parts are then dipped in kerosene and heated. Exceptional care, however, does not have to be devoted to the tools which are used in a forge shop, as they are all more or less of the heavy and rough variety.

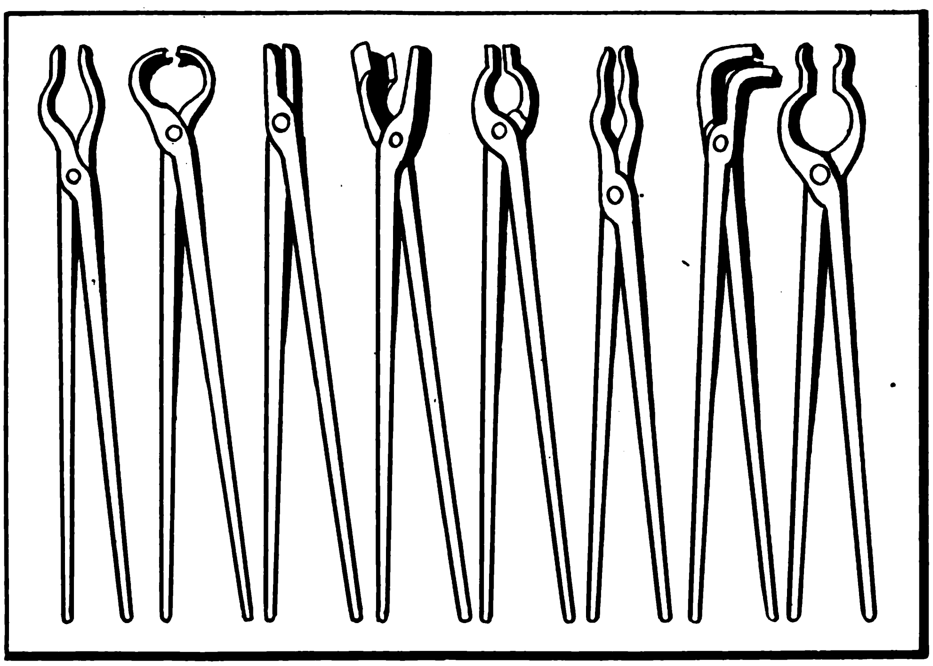

Fig 1—Every pair of tongs in the repair shop has a purpose of its own

CLEANING FILES—Nothing will choke up so readily as a file, and when this is the case the tool is almost absolutely useless because the small particles wedge between the teeth of the file and gradually fill this space up so that in time where the choking process has been going on for an extended period the file will be reduced to little more than a flat piece of metal with occasional minute projections. Long before the file reaches this stage of inefficiency it should be cleaned, as shown in Fig. 3. The brush used for the purpose is seen in Fig. 2 and consists of either two parts or of one only. When composed of two parts there are two different types of brush, one being called a file card, while the other is known as a brush.

The files should be placed in kerosene to soak for a length of time, say over night, before the cleaning is attempted. The file brush and card is then called into use and the file scrubbed by running the brush vigorously along the file in a direction parallel with the teeth so that in this manner the wire bristles will dig the accumulated matter from the center of the groove between the teeth and clean it thoroughly. The file may be dipped from time to time in kerosene while the cleaning process is being carried out in order that the dirt may be kept soft enough for the brush to take effect. When dipping the file into the kerosene it may be shaken about so that the accumulated small particles will be well washed from the surface of the file.

Acid should never under any circumstances be used on a file to clean copper or other accumulated matter from the file. It is very true that the acid will attack the copper and cut it away from the file by combining with it chemically; still at the same time the acid will also affect the file and do it considerable damage if it is left in contact with it for any length of time.

The file card and brush is an inexpensive tool which may be purchased at a very small price from any hardware establishment. It will repay the expenditure incurred in its purchase by increasing the life of the file and shortening the necessary time of the operations performed with these tools owing to the better cutting qualities of the tool when clean and sharp. The use of a little elbow grease will probably be required to clean the file thoroughly, but it will be amply repaid by the results obtained and the trouble saved by its use.

The item of time saved is often overlooked in small shop practice; but minutes saved, when added together, go a long way toward keeping down the expenses. Time is figured very accurately in dollars and cents in the larger concerns, and there is no reason why it should not be as carefully watched in the smaller shops; for although it does not amount to as large an item by itself, it is still the same relative part of the whole.

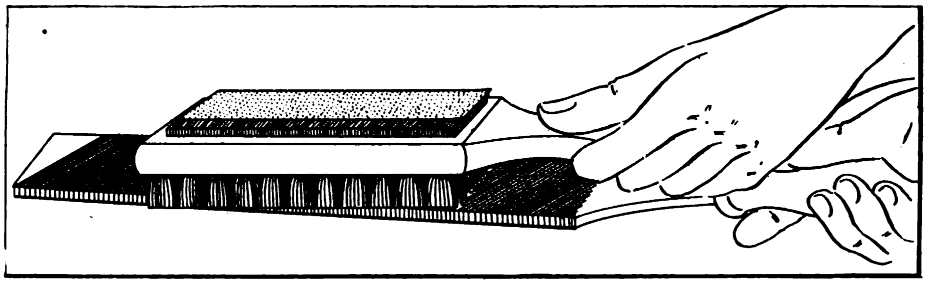

Fig. 3—After the file has been soaked in kerosene the brush is applied

Forge Is of Use—The portable forge is an instrument which is of considerable use about the garage if it is fitted up to carry out repairs of a more complicated nature. There will be many cases where the parts to be repaired will require heating. When the parts to be thus treated are of sufficient size to be heated in the forge, that is, when the other and smaller means are not available to heat the part to the required temperature owing to its thickness, the forge will be a necessary purchase unless all the work is to be sent out.

The city man's garage will hardly be fitted with a forge if he is a private owner of a car, but if repair work is done on an extensive scale, as in a professional shop where outside work is carried on, it will of course be a necessity. A place where the forge will also be of use not only for automobile repairs but also for a variety of other work will be upon a farm or at a country home where a hired man or several, according to the size and equipment of the place, carry on all the work to be done on all the details of the establishment.

In the installation of the forge it must be remembered that various noxious fumes will be given forth while the work is being carried on. The forge should, therefore, be placed near the door in such a way that the heated gases given off by the more or less volatile fuel used are safely led outdoors instead of remaining within the building to produce severe headaches and other unpleasantnesses for the workmen who are engaged within the building. The piping should also be short so as to reduce the cost of installation as well as the trouble and expense of the upkeep of a more extensive ventilation system.

Another reason which would almost be sufficient in itself to determine the position of the forge in the building, especially if it be placed within the basement of the shop, as is generally the case with the forge, is the fact that it will be used in Summer as well as in Winter. The forge, owing to the high temperature at which it is worked, will give off a tremendous amount of heat to the surrounding air in spite of the most elaborate precautions to exhaust as rapidly as possible the gases given forth. It is well to install a good blower fan in the draught line to expel all the vapors from the shop as speedily as possible in order to keep it cool in the Summer season as well as to keep the air as pure as is possible while working with the forge.

If a trap-door is convenient it would be well to have the forge placed directly at the foot of the stairs leading down therefrom, as in this way the problem of leading the piping out of the basement becomes very simple, since there are no bends in the piping and hence nothing to check the freedom of the passage of the gases from the building. If there is a lathe in the shop it would be well to have a forge with such an arrangement that the belting can be attached to the fan; but if the hand variety must be installed, the type shown in Fig. 4 with the semi-hood is a good one to use.

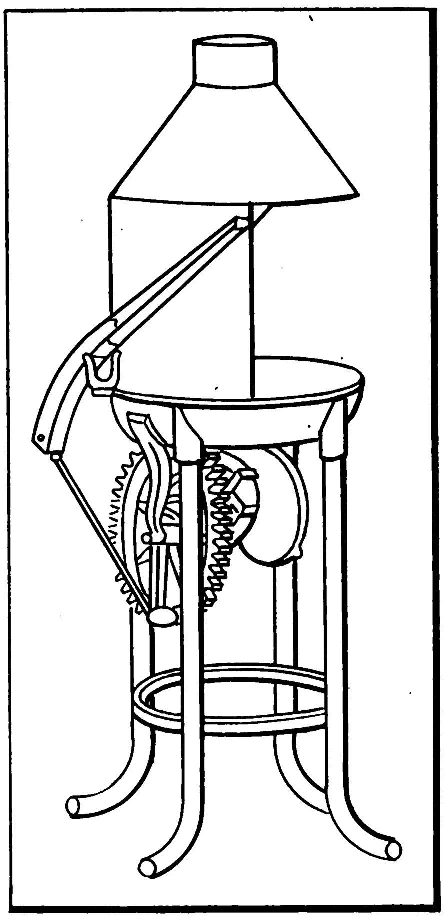

Fig. 4—A portable forge of the hand variety is equally useful in a shop and country garage

Weak Mixture Caused by Leaks.—Backfiring into the intake will often be caused by a weak mixture and the carbureter will be blamed for the mischief, while in reality it is caused by a leaky intake manifold connection. This may be repaired in various ways, depending upon the method by which the manifold is connected to the cylinder. In case of a dog held by a stud bolt it may be that the dog has been sprung on account of too severe a strain having been placed upon it. Another cause of leakage where the manifold is held by means of a dog is that the gasket needs replacing. In this case it is necessary to carefully remove every part of the old gasket before replacing it with a new one, as it will be found that portions of the old gasket are very apt to adhere to the metal.

After having removed the old gasket the flanges should be filed bright so that there will be no chance of leakage on account of a burr being on the edge of the metal.

Where the manifold is held by means of a bolted flange the leakage is generally due to a defective gasket which is replaced in the same manner as the gasket in the case of a dog-fastened connection.

Care in Grinding Valves—It will very often happen that the emery used in grinding valves will fall into the cylinders if great care is not used to prevent such an occurrence. A preventative in the way of a piece of cotton waste placed in the cylinder port must always be used. In order that it will be a simple matter to withdraw the waste, a piece of string is turned about it before it is put into position. The loose end of the string is then carried out so that when the operation of grinding the valves is completed, it is only necessary to pull the string to remove the waste.

If the emery were to fall into the cylinder the damage which it would cause is almost immeasurable, as it would not only cut the cylinder and piston rings but it would also be very apt to get into the connecting rod and main bearings as well and destroy them.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Wants His Money's Worth

EDITOR THE AUTOMOBILE:

The following is my ideal car for next year: The motor to be used on the five-passenger car will give full 40 horsepower, with a reserve sufficient to meet any emergency. The cylinders are made of close-grained iron and are cast separately for accessibility, while the heads are machined inside to obtain better scavenging and to insure equal compression. The bore is 5 inches and the stroke 5 1-2 inches, not larger, as excessive side pressure of the piston on the cylinder walls would be caused by the large offset used in this motor, and also because an excessively long stroke will neither allow throttling down to very low speed on high gear nor give as good torque at this speed.

The pistons are light and have their heads convex, which gives rigidity, reduces expansion and prevents the collection of oil. The piston pins are held stationary with the pistons to prevent their working loose and damaging the cylinder walls. The drop-forged crankshaft has three bearings of at least 5 inches surface each, and are of the best white brass. Being offset from the center of the cylinders, the surfaces of pistons and cylinders are relieved of much side pressure and, therefore wear, while the power efficiency at low speeds is increased. The flywheel is bolted to the rear of the crankshaft.

The camshaft, also drop-forged, with integral cams, runs on three large annular ball bearings, and is removable through front or crankcase without disturbing the motor's adjustment. The valves are all on the right side, and, like the ports, are very large to permit the free removal of all gases. The vâlve push rods are light and adjustable and, as they raise the valves direct, side thrust and noise are eliminated. They also are covered to keep out the grit. The manifold has easy bends and is of the ejector type, thus avoiding back pressure and increasing the motor efficiency.

The crankcase is constructed with three drop arms, giving a power plant of the three-point suspension type on an underslung frame. The right side of the case contains the main opening. The flywheel, heavy spring motor starter and disc clutch are all enclosed within rear of case, forming a unit-type power plant which, combined with the three-point suspension, overcomes the destructive effects of jolting, raking and the usual tendency to wear and to work out of alignment. The bottom of the crankcase is to contain the oil reservoir, and the oil pump is to be in an accessible place at the rear of the case, being operated from the camshaft by spiral gears. A sight-feed glass is to be on the dash to show that the pump is working. This system of lubrication is automatic, self-contained and requires no adjustment. A gauge is placed under the hood to show at a glance the amount of oil in the reservoir. The spiral-cut timing gears are to run in an oil-tight compartment of the crankcase and are to be so arranged as to be easily removed from the front.

The radiator is of the full honeycomb type and is flexibly suspended just behind the front axle. Water circulation is maintained by a large motor-driven centrifugal pump, with the magneto and cast aluminum fan driven by the same shaft on the left side of the motor. Dual ignition is to be had by one set of plugs over the inlet valves.

The clutch, which is mounted on large annular ball bearings, consists of thirty-three hardened and ground discs of saw-blade steel, and occupies the entire inner diameter of the flywheel.

Back of the clutch, but also housed in a bath of oil, is the automatic self-winding spring motor starter, which turns the motor over several times when a small pedal is pressed. The transmission, of selective type, providing three speeds forward and a reverse, with direct drive on third, is combined with the worm drive in unit with the rear axle, thus attaining simplicity and compactness as well as proper distribution of weight, which means safety and easy riding qualities, and, in combination with the disc clutch, tire economy. The housing of the gearset is of cast aluminum and is bolted direct to the pressed steel differential case. The high gear has four dogs, instead of many teeth, thus saving the danger of stripping. The shafts are mounted on adjustable roller bearings, and chrome nickel and vanadium steels are used here, as in other parts of the car.

The steering gear, mounted on the right side of the car, is strictly irreversible, with all its parts large. The worm and sector are both of chrome nickel steel, hardened and annealed, with an adjustment for wear. They are contained in an aluminum oil-tight case.

The cross-link of the steering gear is thoroughly protected, while a Caster type front axle is used for its many advantages. It is of the I-beam type and is drop-forged. The rear axle is of the full floating type, this being the most accessible and only mechanically perfect axle made. The brakes are of very large surface and, as both sets are of the expanding type, one set of drums is used, giving a neat appearance and keeping out the dirt. The brake rods, which are fitted with equalizers, are within the frame and are easily adjusted by large wing nuts.

The frame is made of deep channel section cold-pressed nickel steel, heat-treated, narrowed in front for short turning and has a very deep and wide middle section, which tapers towards the ends. It is of the underslung type. This system affords great safety in turning, as the springs are so nearly in line with the horizontal center of mass of the car that, instead of being vertically deflected, the load is applied to the side of the springs and, as the springs cannot be laterally deflected, the frame and car retain a horizontal position. The low center of gravity not only makes the straight-line drive possible (which economizes power, only one universal joint being used), but also tends to prevent skidding and turning over. The wheelbase is 132 inches for the five-passenger car, and 142 inches for the seven-passenger. The wheels are of best second growth hickory, with twelve spokes both front and rear. They are equipped with Dorian demountable rims and take 41 x 4 1-2-inch tires.

The gasoline tank is at the rear of the chassis frame and has a capacity of 25 gallons. This tank is constructed of heavy, double-riveted copper, divided by swash plates. It has a large filling cap and also a gauge. The gasoline is forced to the carbureter by air pressure automatically supplied by the motor. The tank being in this position reduces the danger of explosion or fire, and it is filled more easily and without disturbing the passengers.

The springs are long and wide with thin leaves. They are semi-elliptic, front 42 inches, rear 56 inches, and are built under the Pike patent.

The body—deep, low and roomy—is of the straight-line type. Ease and grace are combined. The aluminum footboards, front and rear, are long and sloping to match the deep tilt given the seats. Under the rear footboards are the tool boxes. The running boards are also made of aluminum, and the large hooded dash is fitted with force ventilators to make the use of the fore-doors comfortable. Just above these ventilators, and also built in the dash, are the side lights. The doors are opened electrically by pushing a button on their tops, the horn and lights being operated in a similar manner. The current for these accessories is obtained from a large storage battery located under the front seat. The fenders closely follow the curve of the wheels and, like the hood, are constructed of very heavy enameled steel.

The price of the five-passenger car is $2,000.

The seven-passenger car has a double-drop, overslung frame, platform springs and six-cylinder, 60-horsepower Knight motor, but otherwise it follows the construction of the five-passenger car. The price is $3,000.

A full equipment is put on every car, absolutely no allowance being made if any part of it is not wanted.

WARREN B. MOULTON.

Riverside, Cal.

A 12-Year-Old's Ideal

Editor THE AUTOMOBILE:

I think most people will agree with me in regard to the following specifications which I have set down here for the ideal 1912 car:

The horsepower should be 35 to 40, which gives good power and low consumption of gasoline. The bore should be 4 1-2 inches and the stroke 5 inches, with four cylinders, cast in pairs, which gives the full rating mentioned above. The wheelbase should be 120 inches, giving enough room without making the car too heavy. The car should be shaft-driven, as that is more noiseless than chain drive. There should be three speeds with direct drive on third, geared 3 1-2 to 1. The clutch should be an asbestos fabric-covered cone clutch. The weight should be about 2,800 pounds, and I would use 35 x 4 1-2-inch tires that would give good mileage without being too large. The springs should be elliptic on the rear and semi-elliptic on the front.

I would have a double high-tension magneto system with two sets of spark plugs. The oiling system should be an automatic force-feed through a hollow crankshaft, throwing off oil and lubricating the walls of the cylinder, the camshafts, etc. The brakes should be 17 inches in diameter with a 2 1-2-inch face mounted on the rear axle hubs. The spark and gas levers should be mounted on the steering wheel on the outside, with a foot accelerator on the floor. The rear axle should be of the full floating type and the front axle a forged steel I-section.

The car should be fully equipped with top and windshield, and the cost about $3,000.

ALLEN ADDICKS.

Philadelphia

$2000 for a Real Car

Editor THE AUTOMOBILE:

I cannot resist the tempetation to give my idea of what a pleasure car should be for 1912 or for any other year. My ideal car would have 130-inch wheelbase. The wheels would be 36 inches in diameter with wire spokes, as the wire wheel is both stronger and more resilient. The tires would be 36 x 4, on demountable rims. Both front and rear axles would be I-beam construction, and the frame would be of channel section, double-dropped and inswept at the forward end.

The motor would have six cylinders, cast three together and having seven roller bearings on the crankshaft. The bore would be 4 inches and the stroke 6 inches, and the motor would have the Knight sleeve-valve system. The lubrication would be positive by pump through the crankshaft and cylinder walls. Cooling would be by means of a honeycomb radiator mounted over the front axle and by a rotary pump. The radiator would have a screen fitted in front of it.

The transmission would have three speeds forward and reverse, with a bronze and steel disc clutch, and a thrust block of roller pattern to take up the thrust.

The body would be of aluminum and wood, five-passenger, fore-door, of simple panel design with the drive on the right side. The rear seat would be forward of the rear axle, and the front springs would be semi-elliptic and rear springs full-elliptic, as in the Mercedes. Final drive should be by side chains enclosed in oil-tight cases. This drive is absolutely noiseless and most efficient.

Finally, this car should be built of the very best materials with the best of workmanship, and sold for $2,000 by a real manufacturer. A financier would want $4,500 for it.

E. R. C.

Buffalo, N. Y.

Wants Knight Motor

Editor THE AUTOMOBILE:

My idea of an ideal all-around car is one with Silent-Knight motor of six cylinders, 3 1-2-inch bore and 5-inch stroke. The wheelbase should be 124 inches, tread 56 inches and the wheels should have 12 spokes all around with demountable rims and 36 x 4 1-2-inch tires.

The emergency and foot brake should be on rear wheels, external expanding inside drum for emergency and outside drum for foot brake, 15 inches in diameter, 3 inches wide, with drum bolted to each spoke. The gearset should have four speeds and reverse mounted on annular ball bearings, gears and shafts of nickel steel.

I would specify shaft drive inclosed in torsion tube with one universal joint, drive shaft, pinion and bevel gears nickel steel, rear axle flull floating ball bearing of nickel steel, front axle and steering knuckles also nickel steel. Steering should be by irreversible worm and gear, arm and all connecting rods alloy steel of ample dimensions; this is one of the most important parts of the car and should be extra strong. Springs semi-elliptic in front, three-quarter elliptic on rear, of vanadium steel.

The carbureter should be double-jet, hot-water jacketed, controlled by hand throttle on steering wheel and foot accelerator. Ignition should be by high-tension magneto, lubrication force feed and splash system. The clutch should be a multiple disc, running in oil.

The body should have fore-doors, top, windshield, electric lights, Klaxon horn, trunk rack, tire irons, speedometer, coat and foot rails. Gasoline tank should be hung from frame on rear with pressure feed to carburetor, frame pressed steel heat treated, right-hand drive steering wheel 18 inches in diameter and set low enough to be convenient. There should be about 10 inches clearance.

H. A. TIBBETTS.

Alton, N. H.

$1250, If Quantity-Produced

Editor THE AUTOMOBILE:

The motor of my ideal car would have four cylinders of 4 1-4-inch bore and 4 3-4-inch stroke. The cylinders should be cast in pairs, allowing a three-bearing crankshaft, and the valves should be of the poppet type, extra large, enclosed, and all on the same side of the motor. The crankshaft should be offset 1 inch. The splash system of lubrication should be used, and means should be taken to prevent the oil from running to one end of the crankcase when ascending or descending a hill. I prefer a Splitdorf magneto, and a carbureter which is water-jacketed.

I should prefer the clutch and emergency brake to be operated by a pedal to the left, with a locking device, and the service brake by a pedal to the right. This method of control would be superior, I think, to that suggested by the correspondent who wants the clutch and service brake operated by the same pedal, in that it would allow the service brake to be applied without releasing the clutch when descending a steep hill with the throttle closed and the engine acting as a brake. Either method, however, is good, since it dispenses with the hand lever, which is a nuisance in a fore-door car. The gear shift lever should be low enough to permit easy access to the driver's seat from the right-hand side of the car.

The wheelbase should be about 112 inches, and the body hung low to add to the beauty and riding qualities of the car. I should prefer 34 x 4 quick detachable tires, with an engine-driven air pump for easy inflation. A clear vision windshield would make driving more of a pleasure. A B. and L. Castor front axle would add to the ease of driving and the safety of the occupants of the car.

If this car could be produced in quantity, I fail to see why the price should be more than $1,250, including top, windshield, electric lights and self-starter.

Lancaster, O. E. R. B.

Details of the G. & A. Carbureter

WHILE the desirability of a perfectly automatic carbureter is hardly to be denied, practice has not proved the possibility thereof until this day, and designers have resorted to the construction of semi-automatic working carbureters, *i.e.*, those in which either gasoline or air intake is fixed.

Since internal combustion practice has shown that a motor is much more sensitive in regard to a variation in the quantity of the fuel rather than to an altered amount of oxygen, there seems to be an advantage in the application of a stationary gasoline nozzle. The great army of automobilists are only too apt, in case of a slight disturbance of the working organs of the motor, to try to remedy the trouble by changing the carbureter adjustment, which in nine cases out of ten is innocent of the trouble laid at its door. For this great number of motorists the use of an unalterable gasoline adjustment which serves for a wide range of speeds must be considered a blessing. Thus after deciding on the correct construction of the gasoline supply and nozzle it remains to so design the air-supplying members that they lend themselves as perfectly as possible to the varying demand of the motor for mixture.

In the G. & A. carbureter, a full view of which is seen in Fig. 1, the gasoline on its way to the engine flows through a float chamber, where its maximum level is slightly above the nozzle outlet, which is placed in the plane where the upper widening of the Venturi tube sets in. In Fig. 2, depicting the float chamber in section, the manner of its operation is shown. The top of the chamber is flanged to permit of fixing the cover thereto, and under the cover, in the inner face of the chamber wall, is clamped a plate P1, which, like the cover, is punctured to permit the stem of the needle valve to slide through it. Plate P1 has two vertical downward extensions, pierced by two pins P on which are hinged two weights W and W1, connected by a small round brass plate integral with the needle valve stem. When the chamber is empty the brass float F1 assumes its lowest

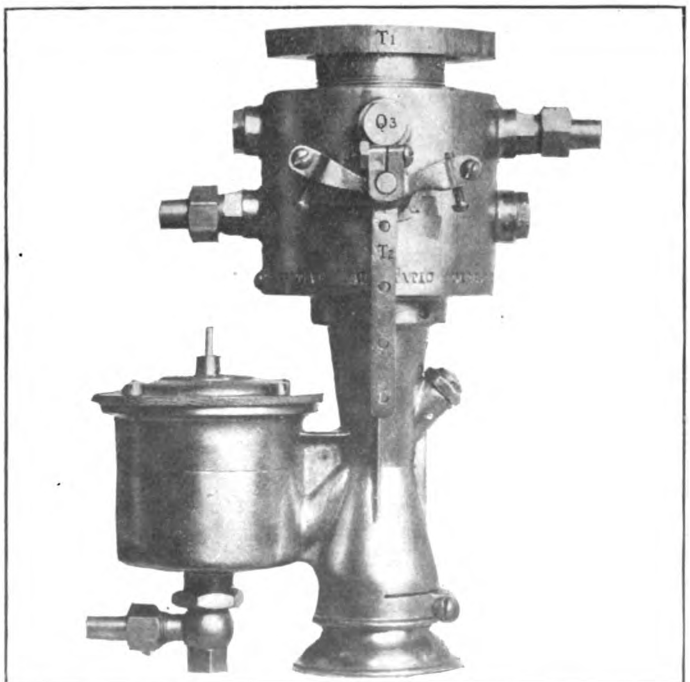

Fig. 1—Outside view of the G. & A. carbureter, indicating strength and compactness

possible position and the weights resting on it and fulcrumed on their pins lift the needle, thus making a free way for the gasoline into the chamber. If gasoline is admitted it lifts the float as high as the weights resting on it permit, at the same time depressing the needle, which closes the valve when the gasoline level is slightly above the nozzle N1 leading up from the float chamber to the mixing chamber C1, so that the fuel flows out into same. The needle valve finds its seat in the brass fitting shown below the float chamber and which is capable of being removed from its place to drain off the gasoline or remove whatever foreign substances may have accumulated in the drainage space closed by plug D1.

The flow of air is regulated by means of the common lever and throttle, the butterfly being shown at B1 in the mixing chamber. The air enters at the lower end V1, of the Venturi tube, after passing through a 30-mesh strainer S1, which serves to keep foreign matter out of the tube. This strainer is attached to a brass funnel of a diameter considerably larger than that of the pipe in order to take in as much air as possible. The Venturi tube, 1 1-2 inches wide at its lower end, narrows upward to a diameter of 9-16 inch and rises then as a parallel pipe for about half an inch. The parallel portion of the air passage is bored to provide a passage for the gasoline nozzle which ends at the upper level of this parallel portion and is almost centered in the pipe. The upper part V2 of the Venturi tube is 3 5-8 inches up to the butterfly, and serves as the mixing chamber for the gasoline and air.

The auxiliary air inlet supplying the motor with an additional amount of air at the higher speds has been constructed in the shape of a series of ball checks. Twelve balls of various diameters rest in cages upon holes in the part M2 of the mixing chamber. About 7-16 inch above the plane of these holes an annular ring is provided. When the throttle is fully opened, the suction of the motor lifts these balls, and draws in air through the seats of the ball valves. Naturally, the smallest balls are first lifted, but their seats represent only small inlets for the outer air, and a stronger suction of the motor lifts the larger balls in their order of size, drawing in more and more air.

As the gasoline leaves the nozzle and is taken up by the swift-moving air streaming toward the motor, the liquid is atomized, *i.e.*, torn apart to form very small globules. But as gasoline cannot be burned completely except when in the gaseous state, designers of carbureters have found it of advantage to preheat the mixture of air and gasoline globules so as to completely vaporize the fuel before it enters the combustion chamber. This is done by water-jacketing the mixing chamber, and the water jacket is seen in Fig. 2 at J1. Apropos of water jackets in carbureters it may be well to remember that a fixed amount of gasoline has a certain heat of evaporation, that is, it absorbs a certain number of thermal units when converted into a vapor. In water-jacketing a carbureter, it is necessary for the designer to bear this in mind, since if not enough heat is supplied by the water to the mixture, the fuel will not be evaporated as completely as is to be desired. On the other hand, if too much hot water passes through the jacket and therefore more than the necessary heat is taken up by the gasoline, the fuel will enter the cylinders not only in vapor form but charged with a certain amount of heat, which goes to expand the mixture—even before it enters the combustion chamber—so that a lesser amount of mixture per stroke is taken into the cylinders. The varied demand for gasoline of the motor at different speeds as well as the changing atmospheric conditions render it impossible to obtain, in a motor, at all times the ideal condition meant by what is called a totally cold compression, and it is therefore left to the designer to consider in his calculations as wide as possible a range of conditions of engine operation and to adapt his design of the details to the average of the requirements found out by his experiment.

The hot water enters and leaves through connections K1 and K2, and the illustration also shows one plug Q4 above one fitting and one Q2 below the other, so that in case a connection interferes with the crankcase or another part of the motor, a plug and fitting situated above one another may be exchanged, their threads being the same, making the connection and plug interchangeable. A third plug Q3 is so placed that it regulates the maximum and minimum opening of the throttle by holding up either of the two side members of the throttle lever T1. A fourth plug is placed on the casting opposite the plug Q3.

One more plug Q1 can be seen in Fig. 2, and this opens the passageway permitting of access to the nozzle when the latter is adjusted before the carbureter goes on the car. This plug is not to be removed except when the work named is being done, since the user of a car will find it of no use, but perhaps of disadvantage, to tinker with the nozzle which is made stationary in order not to be tinkered with.

The top piece T1 is threaded to screw into the top of the space above the throttle and it carries a flange of 7-16 inch thickness for attaching the carbureter to the manifold.

The G. & A. Carbureter Company, of 250 West Forty-ninth street, New York City, makes this carbureter. Several kinds of nozzles are made to fit into the 1912 models of this carbureter, and the company itself in fitting a carbureter to an automobile selects the nozzle that will give the best service and adjusts it to attain this end. When this work is being done it is necessary to unscrew the plug opposite the nozzle outlet in order to get at the threaded pipe connecting float and mixing chambers of the carbureter. After this the plug has filled its mission.

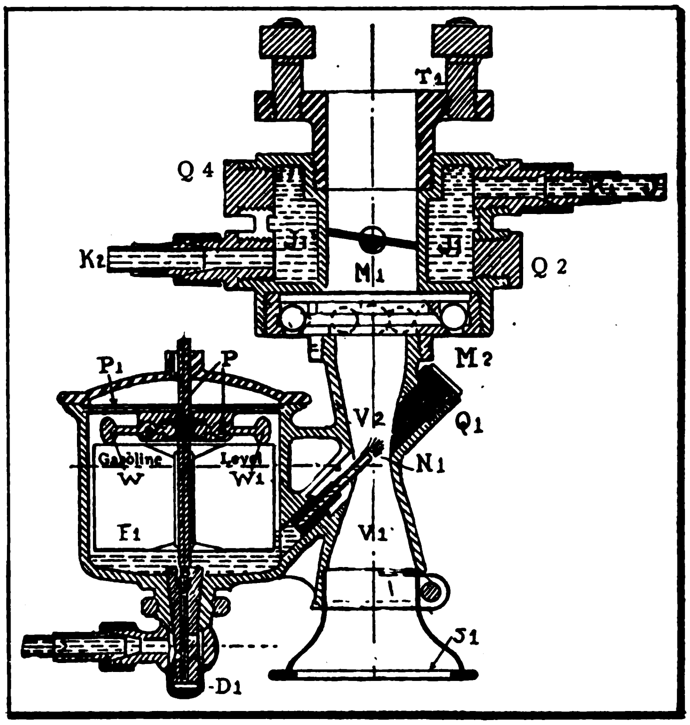

Fig. 2.—Cross section of G. & A. carbureter, illustrating principle of automatic operation

---

GRITTING OF LONDON STREETS.—As the time of the year when street surfaces are often greasy and slippery, owing to weather conditions, is now approaching the Roads Improvement Association of England has addressed a letter to all the Metropolitan Local Authorities of London urging that any material that is used for the gritting of the streets should be as small as possible. It is pointed that the larger material causes damage to rubber tires and is of no service as a preventative of slipping until crushed. The gritting question was very fully considered at a conference between the Institution of Municipal and County Engineers and the Roads Improvement Association last June. The conference then held unanimously urged the thorough cleaning of all highways so as to reduce the necessity of gritting to a minimum and that any material that is used for the purpose should be as small as possible compatible with efficiency.

Calendar of Coming Events

Shows

Nov. 20-25.........Indianapolis, Ind., Fall Show, Indianapolis Automobile Trade Association.
Dec. 30-Jan. 6......Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.
Jan. 2-11...........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 13-27.........Philadelphia, Annual Show, First and Third Regiment Armories, Philadelphia Automobile Trade Association.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 13-19.........Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 22-27.........Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dealers' Association.
Jan. 22-27.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Feb. 3-10..........Montreal, Canada, National Show, Drill Hall, Automobile Club of Canada.
Feb. 5-17..........St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17.........Kansas City, Mo., Annual Show, Convention Hall, Combined Association of Motor Car Dealers.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24.........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association
Feb. 17-24.........Pittsburg, Pa., Second Annual Show, Exposition Bldg., Pittsburg Auto Show Association, Inc.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 20-24.........Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Week Feb. 22......Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.
March 4-9.........Denver, Col., Auditorium, Annual Show.

Meetings, Etc.

Nov. 20-24.........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 22...........Road Users' Day, under direction of Touring Club of America.
Dec. 20...........New York City, Waldorf-Astoria, Annual Banquet of the Automobile Club of America.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Nov. 9-10..........Chicago, Team Match, Amateurs vs. Trade Members to Waukesha and Return, Chicago Automobile Club.
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

The Manufacturer's Burden

THE old adage of "Great oaks from little acorns grow" has its adaptation in the automobile field, and particularly in the contest departments. This was well illustrated in the recent reliability run of the Chicago Motor Club, in which some of the heaviest penalties were caused by very minor incidents at the start. One contestant had a little leak in the gasoline line where it joins with the base of the gasoline tank. This started a long line of trouble. The car body with fenders had to be taken off before the job could be properly soldered, a process which consumed several hours. But this work constituted only one chapter of the affair. While the repairs were being effected the car was falling behind on its schedule; this meant fast driving to catch up. The fast driving resulted in an accident with a farmer, who refused to pull a little to the right side of the road to allow the contesting automobile to pass. The net result was an accident, fenders and running boards torn off against a fence and more penalties for work and being late at the night control. All of this started from a little gasoline leak. Every maker would smile at a buyer who talked seriously over what he considered a weak gasoline feed line from the tank to the carbureter, and yet this proved in this contest a most serious affair, and one that would cost a private owner a good deal of money. The cause may have been a poor soldering job in the assembly room, or it may have been due to excessive vibration caused by fast driving. No matter what the cause, the result is known, and the moral to all car owners and car builders is that a big expense or repair bill may originate with what many would consider a very trifling trouble. The lesson to be gathered is that all of the little details on an automobile should be looked after, because the complete car has but the strength of its weakest part.

But the contest in question afforded one or two other examples of what the little acorn fable is intended to convey. One other contestant had continuous trouble due to a connection on a dry cell breaking off. The connection was broken and the car could not be started on a cold morning on the magneto. Continuous cranking and straining on the starting crank broke the starting crank bracket and more or less trouble followed. Each time the car had to be started it had to be pushed. Two examples will suffice. The truth of the value of the small part is apparent.

The lessons taught by this run should be taken to heart by every maker. They will, if properly applied, prove the greatest salesman of new cars, and they will prove to be big money savers to the automobile owners. Nearly every trouble in a car starts from some little source. The car owner and driver fails to notice the little irregularity which could be corrected in less than 5 minutes. He keeps on driving his automobile from day to day; the trouble grows worse, not perceptibly at first, but soon the owner-driver becomes conscious that something is wrong. He tries to locate it and soon finds that there is a long chain of difficulties; one little trouble has led to another and soon half a dozen parts of his machine have become infected. The repair means several days in the garage, and several days in the garage means a whole lot of money in the repair bill. This big repair bill sets the owner-driver thinking and in nine cases out of ten he comes to the conclusion that what is needed is an inspection department by the branch house or the dealer. The owner-driver is not an apt mechanical physician; he has not the stethoscopic ear to interpret the little knock in the motor that may, if not corrected at once, lead to a new set of bushings for the crankshaft and connecting rods at an outlay of more than \$100. He is not capable of detecting the little clutch slip that, if not corrected at once, may require a new facing or some new disks. He cannot tell if the motor is getting enough lubricant or if the cylinders are filling up with carbon; in a word, he is not an automobile physician. He is not an expert at diagnosing troubles and, worse yet, he is not adept at prescribing remedies. A real doctor of automobiles and their troubles is needed. Each car owner cannot have his private physician. The car maker should supply the physician. The physician is the factory expert—the man who has worked through every department of the factory; the man who understands every in and out of the entire car; the man who can tell in an instant the cause of a certain irregularity, and who is as quick to provide a remedy; the man who can take a 15-minute ride once a month with every car owner and who can tell them in that time if every part of the car is working all right, and if any little symptoms of trouble are noted can suggest the remedy.

The answer to the need for automobile physicians points to the service department, whether conducted directly by the factory or by a competent dealer. The average repairman does not solve the problem. He takes the place of the patent medicine man in the medical field. He is supposed to be able to repair every make of car. How foolish such an idea! How can he make a good repair unless entirely familiar with the construction of the car parts and also familiar with the materials used in these parts and the treatment given these parts in the processes of manufacture? It is true that the repairman can do a great many things and can do them well, but often he fails to do a great many and does a host of others very poorly. He can do the ordinary work well, but fails badly when the more important jobs have to be handled. A few examples will suffice to illustrate this: The repairman in some Nebraska city could not be expected to make a good job with a repair on a bent steering arm on a certain make of car when he was ignorant of the grade of steel used in this part and did not know the heat treatment it was given when it was being made. The same applies to springs, leaves of which have been broken and a temporary repair is wanted until a new spring can be had. In some cases the repairman makes a perfect job, one that will endure; but in others the repaired leaf has not given a day's service. The meaning attached to this is that by a plan of guess work he gave treatment that was well suited in one case; it was just the kind of treatment that grade of spring steel demanded, but in the other case the treatment was perhaps the worst that could be given. Here is where the man trained in the factory can give good service at the branch houses or service departments throughout the country. The modern car calls for trained workmanship and scientific workmanship. In plenty of the cities throughout the country the head repairman is a person who has graduated from some blacksmith shop field. He has never had a thorough experience in the automobile field. His case is similar to calling in a veterinary to treat a human being. Skilled treatment is needed and a man skilled in the treatment of one make of car may be a dismal failure in similar treatments on other makes of cars, simply because different materials are used and these materials have been given different treatments in the processes of manufacture. The crux of the entire situation is that the car maker must look after his customers, otherwise they will get away from him. It will pay each automobile maker to establish service departments in the big centers of population where his car is sold. It will pay him to have a free inspection department, in which once a month each owner can have his car given a 15-minute official run under the control of the automobile physician. If it is running well, nothing has to be done, but if some trouble is developing it can be nipped in the bud. This nipping of troubles in the bud saves the reputation of the car and also saves the pocketbook of the owner. If some work has to be done on the car the owner should pay labor rates for it, and if it be advisable to add some new parts, then he should pay a legitimate price for these parts. It is much better for him to pay $1 to rectify a trouble to-day, which if let run would mean a bill of $100 in less than a month. Service departments are needed. If a maker cannot install gilt-edged departments at once, install poorer ones; but make a start. If it is not satisfactory to open branches and erect big, costly buildings, then install humble quarters with the dealer. But give satisfaction to the owner. Give him intelligent repair service and give it to him at a reasonable cost. Do not try to make money out of the owner because of the failures in your designing or manufacturing departments in turning out automobiles that are not perfect. Be ready to carry your share of the burden. The welfare of the entire automobile industry demands this.

Savannah Card Filling

SAVANNAH, GA., Nov. 8—With the entry list for the four big road races to be decided the latter part of this month reaching a total of thirty-one to-day and with still a full week intervening between to-day and the closing of the entry box, indications point to the coming race meeting as the greatest in the history of automobile racing.

It is understood that there will be at least twenty-five more cars entered and there is a strong probability that even a larger number will try conclusions. The only Indianapolis factory entries so far received have been those of the Marmon fleet consisting of two cars in each the Grand Prize and Vanderbilt and three in the Savannah trophy race. Among the Indiana cars expected in addition to the Marmons are several from the National factory, a Cole or two, a Westcott and perhaps a Stutz car.

Following are the official entries:

G and Prize—3 Fiats, 3 Benz, 2 Marmons, 2 Loziers, 1 Mercedes.

Vanderbilt—2 Mercedes, 3 Fiats, 2 Marmons, 2 Abbotts, 2 Loziers.

Savannah Challenge—2 Cases, 2 Abbotts, 3 Marmons, 2 Mercers.

Tiedeman—2 Abbotts, 3 E-M-Fs.

All of the net profits of the races will go to the military of Savannah. To the efficiency of this well-drilled body is due the absence of accidents on the course in the past, and this disposition of the receipts meets with the approval of all concerned. The detail will consist of six companies of the First Infantry, four companies of heavy artillery, a troop of cavalry, a battery of light artillery, and two divisions of naval reserves. Sheriff Screven and his forces will also assist in the work of guarding the 17-mile course.

Akron Growing Rapidly

AKRON, O., Nov. 6—Due largely to the development of the automobile industry, Akron, the "rubber town," has had the following increases in the five years 1904 to 1909, according to reports just made public by the United States Census Bureau. Division of Manufacturers:

One hundred and eighteen per cent. in the value of manufactured products; 111 per cent. in the value of materials used; 103 per cent. in the amount of capital invested, and 32 per cent. in the number of manufacturing establishments. This is a record for cities of Akron's grade and population, 70,000.

If the figures were taken at the close of 1911 instead of 1909, the results would be still more striking, for the Diamond Rubber Company, the B. F. Goodrich Company, The Firestone Tire & Rubber Company, The Goodyear Tire & Rubber Company and all other tire makers have developed considerably of late.

Thirty thousand Akron people are supported, directly or indirectly, by the rubber industry, and in that industry all possible pressure and concentration is directed to the tire branch.

It is significant that in the improvements and additions made to Akron rubber factories, the best of material and expensive innovations are used. This is explained by leaders of the industry on the ground that they are certain the automobile industry will continue to grow and develop indefinitely and they must build not only for the present, but for the future.

Pittsburgh to Have Two Shows

PITTSBURGH, PA., Nov. 6—There will be two shows held in this city next Spring. The sixth annual show will be held in Duquesne Garden in February, and the second annual exhibition of the Pittsburgh Auto Show Association, Inc., is scheduled for Feb. 17-24.

National Wins Phoenix Desert Race

PHOENIX, ARIZONA, Nov. 7—For the first time in the history of automobile racing, a Western event of national importance has been won 2 years in succession by the same man. Harvey Herrick, who won the Los Angeles-Phoenix road race a year ago in a Kissel car, this year piloted a National to victory. Ralph Hamlin, second last year in the Franklin, used the same machine and took the same position. The National's running time over the 542-mile course was 20 hours and 22 minutes, while that of the Franklin was 22 hours, 54 minutes, 35 seconds. The Midland car, driven by Tom Carrigan, captured third honors, negotiating the distance in 24 hours, 21 minutes and 24 seconds.

The course is a trying one and tested the mettle of men and cars to the utmost. Machines and drivers were covered with thick coats of dust upon their arrival. Several had no sleep from Saturday morning until late Monday night.

For days before the start of the race, Saturday night, there had been no rain and the course was in as good condition as it ever was, but at its best is terrifying. There are stretches of 50 miles without water or human habitation. Herrick took the lead right at the start and maintained it to the finish. He could have finished an hour sooner. Herrick's proverbial luck and the National's staying qualities carried them into San Diego for the special prize of $1,000 for the first car to reach that place, far in advance of the other machines. Then Herrick was off over the sands of southern California, across the brush-covered flats of Mexico to Yuma, Arizona, where he won another $1,000.

He pulled into Yuma, 330 miles from Los Angeles, at 11:49. Sunday morning. His running time had been 12 hours and 14 minutes. Leaving Yuma at 5:03 the next morning the National shot away for Dome, 20 miles distant. He went into control only 1 minute ahead of the Mercer. This was the nearest Herrick came to losing his lead. All the cars were held in control at Dome until they could be hauled across the Gila River. The Franklin and Mercer pressed the National closely this side of the river but gradually Herrick pulled away. The last 150 miles was easy for him, he did not let out the National at all. Once E. Swanson, his mechanician was jolted out but Herrick playfully ran on half a mile, forcing Swanson to scamper along to keep up before he would let him in. At 1:51 1-2 Monday afternoon the National crossed the line at the Arizona Fair Grounds.

Herrick, who was born and reared in Phoenix, received the applause of 7,000 people. The Franklin arrived at 2:35. Hamlin drove a splendid race and but for an unfortunate accident on the California desert might have beaten Herrick. The Franklin broke a spring near El Centra and spent over an hour in a blacksmith's shop. Tom Carrigan took third place with the Midland, a dark horse, because he had better luck than drivers of heavier and faster cars. He had practically no trouble along the route.

A protest which may prevent the Midland being formally awarded third money has been filed with the A. A. A. representative by Louis Nikrent, driver of the Buick No. 12. Nikrent was getting along pretty well until he was this side of Yuma, when part of the Buick's machinery began to give trouble. He decided that he had no chance to win with his car, so when the Buick No. 16, driven by Billie Ferguson, of Bisbee, Arizona, came along he took its wheel. Ferguson's mechanician, Carey King, was left to help Nikrent's mechanician get the disabled car into Phoenix, but the mechanics beat their drivers. They claim that they arrived at 5:03 but found no one to check them in. They were put down as arriving at 5:16. If the protest of Nikrent is allowed, No. 16 will be given third honors. It is claimed that since Nikrent deserted his own car it was disqualified. The Buick 16 was checked in fourth by the local officials, its running time being 26 hours 26 minutes 35 seconds.

The most serious accident of the race occurred to the Fiat. A mile east of San Diego the lights went out and the car crashed into a telegraph pole. Teddy Tetzlaff, the driver, was hurt, while Felix Magone, his mechanician, was seriously injured. Both are in hospital at San Diego. The Fiat was destroyed.

Earl Fancher, mechanician to Earl Smith, the Maxwell driver, is also in San Diego hospital. Twice between Los Angeles and San Diego the Maxwell turned over. Just out of San Diego it turned over the third time, Smith and Fancher being pinned underneath. Roger Stearns, driving the Stoddard-Dayton, stopped to give assistance and lost his chance of beating the National into Yuma. Smith was able to finish the race with another mechanician.

At Santa Ana the Pope-Hartford, a Phoenix car driven by W. D. Tremaine, had one rim fly off the front wheel and crashed into a curbing, breaking two more wheels. It was delayed there 12 hours until new wheels could be secured. Tremaine drove on to San Diego, Yuma and Phoenix and arrived second, though his running time was so great as to preclude him from participation in the prize money. His plucky race after his luck was one of the most sensational features of the contest. His running time between Yuma and Phoenix was better than that of any car except the Cadillac.

W. W. Bramlette, in the Cadillac, made a good showing this side of Yuma, but the other side his time was slow. Hard luck stuck to Roger Stearns and the Stoddard-Dayton. Before he stopped to assist the Maxwell, he had had trouble. Despite delay and trouble he was only 47 minutes behind the National at Yuma, in running time. He had to stop out of control the next morning to put in a new axle and that put him out of the running.

The Mercer, driven by Harris Hanshue, was a serious contender until Dome was passed. It was right up with the Franklin and National but Hanshue got lost and broke a steering knuckle and did not arrive until midnight.

The Flanders negotiated the distance between Los Angeles and Yuma in 16 hours and 43 minutes, putting it in seventh place. A mile out of Yuma it was put out of the race.

Bill LaCassel drove a good race in the E-M-F, arriving in Phoenix at 9:10 Monday evening. Minor troubles delayed him on both sides of the river.

One of the favorites, the Cole, made a poor showing in time. Its engine was jarred loose and it dragged all the way. The Cole arrived this morning.

The Lexington, driven by Charles Bigelow, made a good showing for a comparatively light car. It arrived about midnight after having experienced various tire and engine difficulties.

Only meager reports have been received of the Case, a Phoenix car driven by W. F. Brong which was last seen in a ditch between San Diego and El Centra. Brong and his mechanician were asleep beside it.

Election Day Races at White Plains

WHITE PLAINS, Nov. 8—Election Day was celebrated here with a series of automobile track races on the half-mile track of the fair association. Three races were run: Maxwell (Costello) winning at 10 miles; Abbott-Detroit (Mulhall) at 5 miles and Mercer (Monroe), free-for-all at 10 miles.

National Wins Thrice at Minneapolis

MINNEAPOLIS, Nov. 6—Facing a raw wind blowing across the city, 500 spectators Saturday witnessed the hill climbing contest which was held on Columbia Heights hill under the auspices of the Minnesota Motor Club. Barring the low temperature, conditions were ideal, the road having previously been placed in almost perfect condition.

The time was taken by flagging the timers at the finish line when each car crossed the starting tape. As a result several watches were at variance, being in one instance 6 seconds apart.

National (Reiter), entered by the Northwestern Overland Company, captured three prizes, the George B. Levy, Prest-O-Lite and Hollis Electric trophies going to it. This car won in Division 4 for cars of from 301 to 450 inches displacement, the free-for-all event and for making the best time up the hill regardless of class.

This climb marked the initial appearance of National cars in competition under sanction in the Northwest. The best time recorded for the National was in one of its early trials, when it was piloted up the grade in 19 3-5 seconds. Its best time in the free-for-all was 20 3-5 seconds. Tying for second place in the free-for-all event were the Colby and the Ford entrants, both taking the ascent in 21 3-5 seconds.

In Division 1 the Flanders won the Republic Rubber Company trophy for cars of 160 inches displacement and under. Its time was 23:27 seconds, the average computed by the timers. This car was entered by the Studebaker Corporation and was driven by Simon Rothenberger. There was no other contestant in this division.

By making the fastest time for cars having from 161 to 230 cubic inches the Ford driven by John McDowell secured the trophy given by R. J. Randolph. Al. Wilson's Jackson qualified for the Automobile Equipment trophy, the second prize in this division. His time was 22:49 seconds. Gus Hansom, in a Ford; Dick Stanton, in a Cutting, and an Overland were the other contestants. The time between them was rather close.

It was a pretty fight between the Colby and the Everitt, driven by Matt Miles, when these cars lined up for prizes offered in the 231 to 300-inch displacement class. The Colby won, making the distance in 22 1-5 seconds. By its victory it becomes the possessor of the Empire Tire & Rubber Company's trophy, while that offered by the Superior Oil Company goes to the Everitt, entered by McArthur-Zollars-Thompson.

Art Murphy in a Speedwell, entered by the Hudson-Thurber Company, captured the Van Tilburg Oil Company's cup by finishing second in the event for cars from 301 to 450 inches. This was the event in which the National finished first.

In the big class, a Peerless, entered by T. M. Anderson and driven by Ase Precourt, ran with regular touring body and full equipment. This car won the event in the 451 to 600 class, making the climb in 27 1-5 seconds. The Pure Oil Company had offered a trophy for the winner. M. R. Nyman in an Alco finished second in the event. His time was 31 second. The Alco also was equipped with a heavy body.

The climb was 1,300 feet long, with an average grade amounting to 6.63 per cent. The greatest grade at any one place was 10.4 per cent., while the total elevation was 86.2 feet.

Quakers Abandon Reliability Run

PHILADELPHIA, Nov. 4—Owing to the small number of entries received for the Philadelphia Reliability Run, scheduled for November 2-4, and the general lack of interest in the event, the Quaker City Motor Club decided not to attempt to hold it. The club regretted to give up the project, as its runs have always been so successful and so productive of pleasure and profitable experience to both participants and officials.

It is thought that the lack of interest shown in the run is due, in some measure, to the concentration of the attention of the automobile public of Philadelphia on the Fairmount Park Race.

Wisconsin to Educate Public

MILWAUKEE, Nov. 6—The new Wisconsin Highway Commission created by a law appropriating $350,000 annually for State aid for highway improvements will on November 14 put in effect a comprehensive educational plan covering about half the State and with particular reference to the localities that have availed themselves of State aid by appropriating sums for good roads work.

The members of the commission and its engineers will address county and town boards on the provisions of the law and on highway improvement in general.

The speakers will be: John A. Hazelwood, chairman; Senator John S. Donald, Senator E. E. Browne, A. R. Hirst, State highway engineer; M. W. Torkelson, bridge engineer, and W. C. Buetow, assistant bridge engineer. Each of the meetings will be made into a "Good Roads" rally and the entire scheme will be one of the greatest value from an educational standpoint that good roads workers in Wisconsin have ever experienced.

Milwaukee Is After Boy Drivers

MILWAUKEE, WIS., Nov. 6—To prohibit any person under 21 years of age from operating motor cars in the city of Milwaukee is the object of an ordinance now being framed by the Municipal administration for presentation to the common council. The proposition has aroused a storm of indignation and it is thought at this time that such a law will have slight changes for passage.

The object of the ordinance is claimed to be to curb "joy-riding" instincts of the young. It would also prohibit girls under 18 years of age from being in any motor car operated by any person under 21 years of age, unless they have the consent of parents or guardians.

Leading attorneys doubt the right of the municipality to legislate all persons under 21 from operating motor cars. It would be an encroachment upon the State law, which restricts the operation of motor vehicles to all persons over 16 years, excepting that a person 16 years or younger may drive when accompanied by parent or guardian.

Touring and Camping—The Ideal Vacation

The recent Summer season saw more people than ever before enjoying the delights of automobile touring. One of the most interesting which has come to our notice is that made by Mr. W. M. Leftwich, a prominent engineer of Nashville, Tenn. Mr. Leftwich decided to make his tour a "go-as-you-please" affair, not planning to reach a given point each night. In order to accomplish this he carried sleeping bags for the party of seven, and also included a compact cooking outfit. His big six-cylinder Locomobile afforded ample room for this equipment.

The route led from Nashville, Tenn., through Kentucky, Ohio, New York and New England, into Canada, which was entered twice on the trip, Quebec being the first place visited, and later on the party toured in quaint old Nova Scotia. The tour covered over 5,000 miles.

T. C. A. Scouts Arrive at Richmond

RICHMOND, VA., Nov. 6—The cars containing the good roads scouts of the Touring Club of America arrived in Richmond at 3 p. m. Saturday afternoon, having covered the entire distance of 725 miles since Tuesday morning at 11 o'clock. This trip was undertaken to lay out a practicable route for good roads enthusiasts who want to make the trip by auto from Atlanta to the first annual Road Congress of the American Association for Highway Improvement, which takes place at Richmond, November 22.

The cars used in making this trip were the Chalmers Six, which was an official press car for the Glidden Tour. This car was taken off the train Tuesday morning at 9 o'clock and was immediately put into service for the run without any repairs or attention other than filling up with oil and gasoline. The car reached Richmond in perfect condition and without any tire trouble whatever, although the roads were anything but smooth. In this car were Henry MacNair, editor of the *Blue Book*, pilot of the party; W. Douglas Gordon, Police Commissioner of Richmond and correspondent of the *Times-Dispatch;* Lee A. Folger, manager of the Gordon Motor Company, of Richmond, and W. A. Vibbert, official photographer, who was also on the Glidden Tour. The car was driven by Freeman Monroe, of the Chalmers factory in Detroit. The second car was a Mitchell Six, carrying Frederick H. Elliott, secretary of the Touring Club of America; D. D. Armstrong, vice-president and manager of the Southern department of the T. C. A., and H. B. Varner, editor of *Southern Good Roads*. The car was driven by Chas. T. Oley, of the Mitchell factory at Racine. Both the cars came through without any serious mishap, although the Mitchell was slightly delayed on the last day by tire trouble.

The party left Georgian Terrace at Atlanta on Tuesday morning at 11 o'clock and arrived in Augusta at 9:30 p. m.

In Augusta they were met by E. J. Watson, Commissioner of Agriculture of South Carolina, and party, who escorted the cars to Columbia the next day. Some of the road was very rough and the escort car broke a front axle in one of the chuckholes. At Columbia the party was met by many prominent citizens and was entertained at the Columbia and Metropolitan clubs. The next day's run was from Columbia to Pinehurst, a distance of 175 miles, nearly all of which is good sand-clay road.

At Pinehurst the party was met by Leonard Tufts, president of the Capital Highway Association, who entertained them royally and piloted them out of town next day over a new sand-clay road which is being constructed between Pinehurst and Fayetteville. Between Fayetteville and Raleigh the going was the worst of the trip, but Cumberland County has issued bonds for $200,000 which will be immediately used for building sand-clay roads. A luncheon stop was made at Raleigh and the party pushed on to Henderson, N. C., for the night stop.

At Henderson an early start was made Saturday morning and between Barley and Emporia, Va., the finest road was negotiated. This, as with all of the other good roads on the trip, was sand-clay costing about $500 a mile. The cars traveled along on this trip at forty miles an hour as comfortably as on the finest macadam boulevard. But beyond Emporia the going was very bad.

At Petersburg an escort party headed by W. T. Daloney met the cars. The road from Petersburg to Richmond is also sand-clay road and has been recently resurfaced so that the last 22 miles of the distance were made in 40 minutes. The tourists were loud in their praises of the hospitality and enthusiasm along the line. The consensus of opinion is that with very little work and a moderate sum of money the entire trip from Atlanta to Richmond can be made to compare with any similar trip in the Northern States.

The complete official program for the congress is as follows:

NATIONAL DAY, NOVEMBER 20.

Morning Session—Address by Governor William H. Mann, of Virginia; address of welcome by Hon. D. C. Richardson, Mayor of Richmond; opening address by Logan Waller Page, president of the American Association for Highway Improvements; address by William Howard Taft, president of the United States; address by W. W. Finley, president of the Southern Railway Company; address by Hon. J. Hampton Moore, of Philadelphia, president of the Atlantic Deeper Waterways Association.

Afternoon Session—Address by Hon. Thomas S. Martin and Hon. Claude A. Swanson, United States Senators from Virginia.

Evening—Smoker at the Jefferson Hotel, arranged by the Chamber of Commerce and the city of Richmond.

CONTRACTORS' DAY, NOVEMBER 21.

Harold Parker, chairman; chairman's address; address by W. A. McLean, Toronto, Canada; address by P. St. Julien Wilson, State Highway Commissioner of Virginia; address by J. B. Girand, territorial engineer of Arizona; address by W. W. Cosby, State Highway Engineer of Maryland; address by Arthur H. Blanchard, professor of highway engineering, Columbian University.

Afternoon—Addresses by D. L. Hough, president United Engineering and Contracting Company; Mr. Bates and other contractors. Discussion, "The Relation of the Road Contractor to the Engineer."

Evening—Reception in Governor's mansion to all delegates.

ROAD USERS' DAY, NOVEMBER 22.

Address of welcome on behalf of the automobilists of Virginia, Preston Belvin, president of the Virginia Automobile Association; addresses by Hugh Chalmers, Detroit; Sidney A. Gorham, Chicago; Matthew S. Rogers, secretary State of Connecticut, "What It Has Done for Good Roads"; Colonel Charles Clifton, of Buffalo; Davis Dancroft, Chicago; Henry Fairfax, Virginia; Edward Lazansky, secretary of State of New York.

ASSOCIATION DAY, NOVEMBER 23.

Dr. Joseph Hyde Pratt, State geologist of North Carolina, presiding. Address on the use of convict labor in road building by Dr. Pratt. Discussion opened by S. W. McCallie, State geologist of Georgia. Other discussions of this session will be participated in by Jesse Taylor, secretary of the Ohio Good Roads Federation; W. D. Brown, editor *Rural Free Delivery News;* Leslie T. McCleary, of New York, representing the Lincoln Memorial Association; Dudley Field Malone, of the National Highways Protective Society, of New York; representatives of automobile associations, national civic federations and representatives of farmers' and labor organizations.

The afternoon session will be devoted to the election of officers of the association, selection of place for next meeting and the transaction of other business.

President Taft to Be Guest of A. C. A.

President Taft will be the guest of honor at the annual banquet of the Automobile Club of America, which is to be held at the Waldorf-Astoria on December 20. Fully 1,500 club members and their guests are expected to be in attendance.

In addition to President Taft the invited guests will include Vice-president Sherman, the Secretaries of State, War, Navy, Treasury, Agriculture, Commerce and Labor and Interior; Postmaster-General, Attorney-General and the Solicitor-General.

Body Styles at the Berlin Show

According to German contemporaries, the considerable extent to which professionally educated artists, who abound in Germany, have lent their services to automobile manufacturers and body builders during the past year is one feature in the recent industrial development which has left its mark most plainly on the vehicles exhibited at Berlin. The departures from current styles in body design and equipment are bold and numerous. Some of them are dashing; others only help out utilitarian purpose.

In a general way it is noticeable that design runs to long continuous lines with a somewhat studied avoidance of mouldings and corners. The Utermoehle firm has succeeded in producing a phaeton which can be converted into a limousine and yet presents none of the makeshift lines, from an artistic standpoint considered, which have heretofore always been characteristic of convertible types. The same vehicle is equipped with extra-seats which disappear invisibly in the back of the front seats when not wanted, a single lever movement sufficing to throw each of them in or out. A large number of closed cars are provided with frameless window panes of a new patented style, and specially suspended armchair seats, known as the Wildening *Schwebesitz* or floating seat, are a new article of luxury intercepting practically all vehicle movement arising from sudden starts, stops and road shocks. The Kellner firm, which has nothing to do with Paris firm of the same name, seems to shake new ideas out of its sleeves. Its open car bodies are equipped with an electric light, designated as a map-reading lamp but equally useful for reading newspapers in the open. and its interior upholstering of limousines, all in leather, including the ceiling, produces an entirely novel effect of elegance, largely because the firm seems to have developed a new technique in leather finish. And it is said to have spent large sums for its experiments in this departure. Hunting cars in natural wood finish and with very strongly curved surfaces also present a striking effect, while the Windhoff limousine in Prince Henry style, very pointed in front and rounded at the rear and mentioned as the "type of the future," seems somewhat fantastic.

The use of windshields for rear as well as front seats is observed in a number of vehicles.

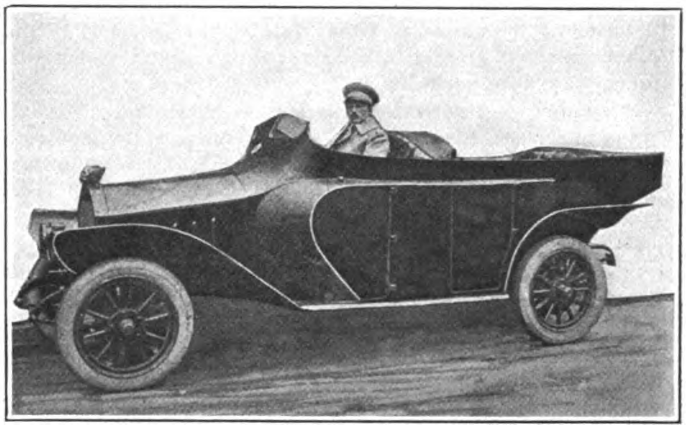
A modern demand for having all accessories disposed of inside of the carriage body accounts for the conspicuous novelty in the body design placed upon a Benz chassis by the Carl Toenjes firm of Delmenhorst. The lines are shown in the accompanying illustration copied from a half-tone in *Allgemeine Automobil Zeitung*. Even the travelling trunks are here protected against dust and grime and the spare tires rest on the running board inside of the side panel. The latter is not vertical but leans outward at the top. All the lines, particularly at the rear are designed with a view to reducing air resistance below that encountered in cars of customary design, and also to avoiding that formation of eddies which raises the dust of the road. In this instance the co-operation of a firm of artists —Ernst Neumann—is distinctly acknowledged, though the type is announced as only a first attempt to become the foundation for further efforts.

Impressions of an American Visitor.

Berlin, Oct. 21.—One of the most striking features of the International Automobile Show from an American point of view is the entire absence of six-cylinder cars. Not a single German manufacturer is exhibiting a car of this type, and the only one that does exhibit such a car is the English Daimler, which has a beautiful six-cylinder chassis with Knight engine on exhibition. [A six-cylinder Protos car is also shown.—Ed.]

Another very marked tendency is the bringing out of low-powered and low-priced models by many of the European manufacturers with the evident intention of preventing the capture of this class of trade by the American manufacturers who are now making a strong effort to secure the market for cheap cars. The only American cars exhibited are Ford, Mitchell, E-M-F and Flanders. The European manufacturers who exhibit cars of this class include Adler, Laurin and Klement, Stoewer and the French firm Clement-Bayard, and others. Each of the companies named exhibit four-cylinder cars ranging from $900 to $1,300 completely equipped. One of the best examples of this type is a very smart little four-seated torpedo by Laurin and Klement, listed at $1,275, and said to be capable of fifty miles an hour on the road.

A line of cars of striking originality in body design is very much in evidence. This is a type known as the Prince Henry, and is cigar-shaped. The hood is extended in a funnel-shaped manner to include the dash, which in many cases contains the gasoline tank, and this is so built into the dash as to be entirely out of the way, and the filler is in the centre on the front, so that it can be filled without disturbing any part of the interior of the car; the filler is practically the same as the radiator cap. The body is long and narrow with only two seats in the rear with a handsomely upholstered arm rest between them, and in many models there are two folding seats, and the back of the front seats are in some cases upholstered in leather and in others are used as cupboards for carrying various articles that may be needed. The dash extends well back and flares up so as to help deflect the wind from the occupants of the front seats. The back of the front seats also have this same flare with the object of protecting the occupants of the rear seats. The general appearance of this type of body is pleasing, and it is rounded off at the rear so as to avoid as much as possible eddying currents of air which would otherwise tend to stir up dust.



Side view of the all-enclosing carriage body placed upon a Benz chassis by the Delmenhorst Wagon Company

The Minerva and Daimler exhibits of working models of the Knight engine with portions cut away to show the mechanism attract great attention and their stands are constantly crowded with visitors. The Minerva Company exhebits a 26-horsepower chassis with 1912 model engine with chain drive for pump and magneto, the latter having automatic advance ignition with only one lever on the steering wheel.

News of Shows—National and Local

SHOW announcements in New York were scarce again during the past week. The chief happening was the progress noted in the Palace show arrangements. As was chronicled at the time of the allotment of space to the Gramm and Kelly trucks in THE AUTOMOBILE, a protest was made giving those companies space on the second floor.

Mr. Gramm entered an informal objection to such an allotment and this week it has been announced that both the Gramm and Kelly vehicles will be shown on the main floor in conjunction with the pleasure automobiles.

It was the original intention of the National Association of Automobile Manufacturers to exhibit all the trucks on the main floor, around the other exhibits. This plan was later modified and the trucks were spaced in the second floor. As it is now, all the trucks except the Gramms and Kellys will be gathered on the second floor.

Accessory manufacturers sufficient to take up a large amount of space on the third floor have already been signed up and the prediction is made by officers of the association that all the space will be contracted for before the end of another week.

Show Arrangements in Quaker City

PHILADELPHIA, Nov. 6—Philadelphia's annual automobile show, again under the auspices of the Philadelphia Automobile Trade Association, will be held from Saturday, January 13, to Saturday, January 27, 1912, inclusive.

A building of sufficient proportions to house the entire exhibition under a single roof still being conspicuous by its absence, the same arrangements for accommodations as were in force last year will apply to this year's show, it being held simultaneously in two separate buildings, uptown in the First Regiment Armory, Broad and Callowhill streets, right in the heart of the automobile selling district, and downtown in the Third Regiment Armory, Broad and Wharton streets.

The first-named building during the initial week will be devoted to gasoline pleasure cars exclusively, the downtown structure to gasoline pleasure cars and accessories. For the second week the scene will be shifted at both armories—the gasoline cars uptown giving way to electrics and electrical devices, while downtown gasoline and electric commercial vehicles will hold the boards.

The Trade Association has appointed the following officers of the show: George W. Hipple, of the Chalmers-Hipple Motor Car Company, president of the Philadelphia Automobile Trade Association, to be chairman; Frank Eveland, manager of the A. G. Spalding branch, handling the Stevens-Duryea car, and J. A. Wister, of Gawthrop & Wister, agents for the Elmore and Brush. J. H. Beck will again manage the show for the fifth consecutive year.

Milwaukee Show Date Advanced One Week

MILWAUKEE, WIS., Nov. 6—The Milwaukee Automobile Dealers' Association has decided to hold its second annual motor show in the Auditorium beginning on January 13, and closing on January 19, instead of from Jan. 20 to 26, as previously announced.

More than 65,000 square feet of floor space will be used for the 1912 show, which is the fourth to be held in Milwaukee. The first two shows were given by the Milwaukee Automobile Club.

Only cars represented by Milwaukee county agencies will be permitted in the display, as last year, when 53 pleasure car makers and 17 commercial vehicle manufacturers were represented. Since last January, 29 additional pleasure cars have gained representation in the city and 14 more commercial car builders have been added to the list handled here.

Frank J. Edwards, manager of the Kissel Kar Co., has been appointed chairman of the show committee and Bart J. Ruddle will again act as general manager. The other members of the show committee are: Edgar Sanger, representing the Maxwell, Stearns and Columbia; Alfred Reeke, manager of the Milwaukee branch of the Thomas B. Jeffery Company; George W. Browne, distributor for the Overland and Marmon, and Robert G. Bates, agent for the Abbott-Detroit and White cars.

But One Show in Kansas City

KANSAS CITY, MO., Nov. 6—Kansas City is to have but one show this year. Last year, and the year before, owing to a disagreement among the dealers, two shows were given; but the antagonistic factions have agreed on the matters that were keeping them apart and one association has been formed, which includes all of the dealers in the city. The membership consists of more than sixty different companies, so that the coming show will be an immense one. It will take place in Convention Hall, which is the largest building for exhibition purposes in the West. Two balconies, in addition to the one already in the hall, will be necessary to accommodate all the dealers and the big accessory department.

Kansas City shows are always important events, owing to the fact that Kansas City is the gateway to the Great Southwest, a section in which more cars are sold annually than in any other locality of equal area in the United States.

The date of the show is the week of February 12th, 1912. There will be departments for gasoline pleasure cars, electric pleasure cars, commercial cars, motor cycles and accessories. The committee which will have charge of the show has established offices at 911 Floyd Building.

St. Louis Dealers Announce Show

ST. LOUIS, Nov. 6—A two-week automobile show is announced for St. Louis Feb. 5 to 17 at the Coliseum, by the same dealers who participated in the show held there last Winter. This will make the second exhibit to be given in St. Louis this season, an open air show having been successfully carried through early in October.

The coming exhibit, like those of Chicago and New York, will be divided into two parts. The first week will be devoted to the display of pleasure cars and accessories, and the second week to motor trucks. This will be the first time a two-week exhibit has been tried in St. Louis, and also will be the initial exclusive truck display.

Omaha's Show Ideas Expanding

OMAHA, Nov. 6—The annual meeting of the Omaha Automobile Show Dealer's Association was held last week. It was decided to hold the automobile show some time in the latter part of February. In previous years the show has been held at the auditorium and the dealers have been cramped for space. This year the association is planning to hold the show at the Coliseum, the home of the Knights of Ak-Sar-Ben of Omaha. The floor space in the Coliseum is about double that of the other building, although it is not so centrally located. Twelve new members were admitted to the association.

The following officers were elected: J. J. Deright, president; J. T. Stewart, vice-president; Clark G. Powell, secretary and treasurer. The board of directors includes the officers and Guy L. Smith and Denise Barkalow. Mr. Powell will be manager of the show again.

Hoosiers to Hold a Fall Show

INDIANAPOLIS, IND.—Arrangements are being made by the Indianapolis Automobile Trade Association for a motor show to be held Nov. 20-25, the first Fall show Indianapolis has ever had. Fred I. Willis, who recently became identified with the Kokomo Rubber Co., Kokomo, has asked to be relieved of his duties as president of the association, and Harry A. Archey, first vice-president, is presiding over the club. It is probable that the association members, during the show, will furnish cars for a free 'bus service to carry visitors to and from the various salesrooms. Each dealer will exhibit in his own establishment. The association has adopted a resolution against the lending of cars for any purpose, charitable, or otherwise, unless the proposed lending is passed on favorably by the directors. Another resolution adopted provides that all requests for contributions or advertising for programs, or other things not directly identified with the motor car trade shall be referred to the association's secretary for recommendation.

Exhibition Planned for Baltimore

BALTIMORE, MD., Nov. 6—While no definite plans have been made, the Automobile Club of Maryland and the Baltimore Automobile Dealers' Association are working on the proposition and expect to announce show dates in the near future.

It is known that either the middle or latter part of February is favored, but those having charge of the affair in both associations do not care to decide on any definite date until they are sure that the time they select will not conflict with the shows in New York, Chicago, Philadelphia and other large cities. A general meeting of the Dealers' Association will be held in the near future.

Optimism in Industry at Detroit

DETROIT, MICH., Nov. 6—Following a most satisfactory October, November has come in full of promise for the local motor industry. Some of the manufacturers are already beginning to predict that 1912 will be the greatest year in the history of the business, in spite of the presidential election and the business disturbance that almost inevitably accompanies such an event.

Hugh Chalmers, president of the Chalmers Motor Company, in a talk before the men in attendance at the Chalmers technical convention last week, expressed the belief that 1912 would set a new record for sales of motor cars. For the first four months of the 1912 season the company's shipments show an increase of 35.3 per cent. over the same period last year. The factory is being operated up to its full capacity, working both day and night shifts.

The Chalmers technical convention will end this week. The attendance will not be confined to men from any one section, but service men from all parts of the country, who have not been able to come earlier, will take advantage of this opportunity to see just how Chalmers cars are made and to get into closer personal touch with the makers. The convention has been a great eye-opener for some of the visitors, and the company feels that the results achieved more than compensate for the monetary outlay.

The Ford Motor Company reports that it manufactured and sold nearly 4,000 cars during October. The output will be greatly increased, it is expected, when the new addition, now rapidly nearing completion, is put in operation early in December. The company is hopeful of breaking even the record of last May, when 6,013 cars were shipped, before the Winter is over.

That the other Detroit makers are sharing in this prosperity is shown by the extensive building operations under way. Mention has previously been made of several of the new plants and additions under construction, but of the building of motor car factories there seems to be no end, in this city at least. Work has been begun on a new garage for the Hupp Corporation at Jefferson avenue and Gilbert street, in the Fairview district, just two blocks from the company's plant. The building will be ready for occupancy about January 1. It will be used for displaying and storing R. C. H. cars. The garage will be 62 x 125 feet and will be a very ornamental structure.

A tract of land comprising 100 acres at Woodward avenue and the 9-mile road has just been purchased by Walter C. Piper, and it is understood that half of the property will be used as a site for a monster automobile plant, the remainder being subdivided into lots for the employees. It is not known, as yet, what company intends building here. The price paid for the land was about $85,000.

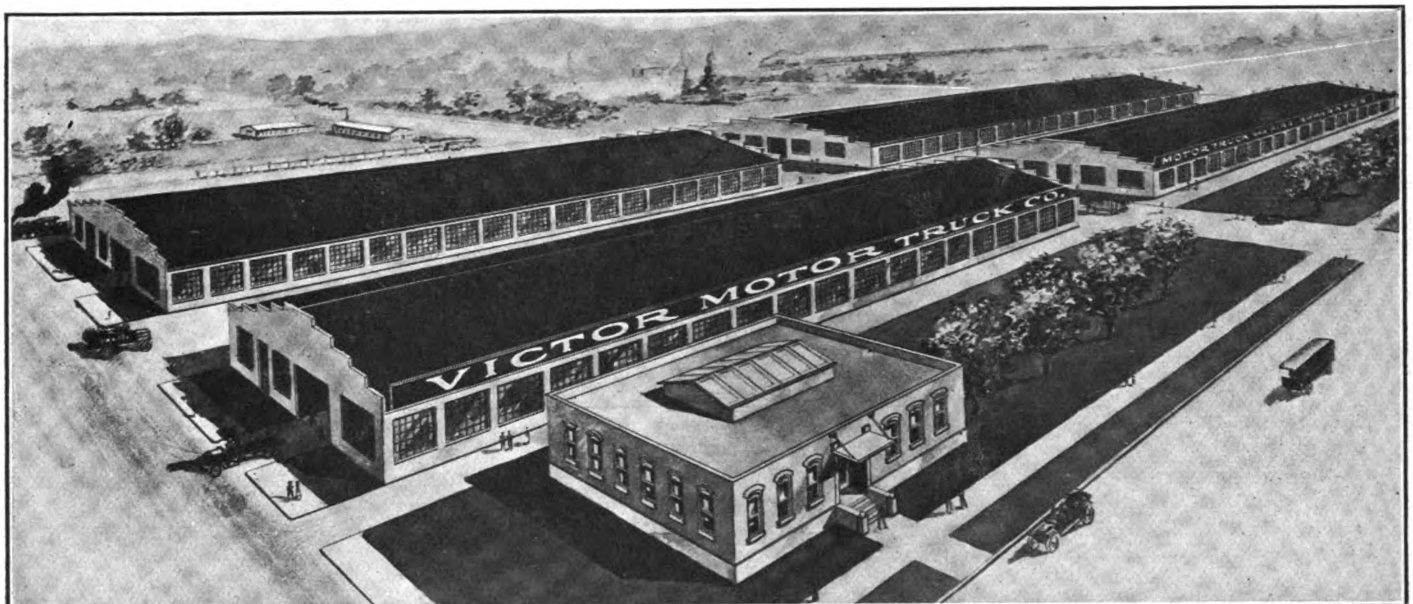
The Detroit Bi-Car Company has been organized with a capital of $100,000, to manufacture the "Bi-Car," which is described as a motorcycle embodying some of the features of an automobile. It is driven by a four-cylinder, four-cycle engine, started by a crank at the side. It has two speeds and a neutral, operated by a regular shaft drive. The company has established a temporary factory at Greenwood and Baltimore avenues, but plans to build later. The officers are: President, John J. Chapin, who is also the inventor of the machine; vice-president, Alfred Roseroot; secretary, John J. Berkery; treasurer, Frank J. Gorman.

The Wolverine Automobile Club is making arrangements for its third under-sealed-orders run next Sunday, the officials having mapped out the route yesterday. The trophy for this run will be donated by Robert K. Davis, of the United Motor Detroit Company. C. A. Smith, driving a Hupmobile, was the winner of the second run, a week ago. He came within 4 minutes of the official time, which was 6 hours and 39 minutes, an average of 13.28 miles per hour.

Atlanta Dealers Win a Home

ATLANTA, GA., Nov. 6—The Atlanta Automobile Dealers and Accessory Association has won itself a home. It accomplished this feat by amalgamating with the Transportation Club in a new organization which will be known as the Atlanta Auto-Transportation Club.

The full breadth of the scheme that the dealers' association is working on has not appeared in the newspapers yet, but it is planned within the year to absorb the Transportation Club entirely and to make a straight automobile dealers' club out of the affair. With Atlanta the center of the automobile business in the South the dealers have long felt the need of some place of their own where they could entertain guests, meet to transact business and thus preserve an active organization.



NEWS of the WEEK CONDENSED

BUFFALO, N. Y.—The new plant of the Victor Motor Truck Company is being built on a large plot of ground secured by the company on the Military Road and alongside the New York Central Railroad. The new building will possess all the advantages essential to efficient production of the various types of trucks made by the company. These include commercial trucks of from 1,500 pounds capacity to 10 tons capacity, and fire trucks of the combination hose wagon, pumping and hose and ladder and hose types.

BUENOS AYRES, S. A.—Prudencio Trejo has taken the agency for the Pullman cars.

BUFFALO, N. Y.—A. W. Meyer has taken the agency for the 1912 line of Pullman cars in Buffalo and northern New York.

LANSING, MICH. — The Olds Motor Works, of this city, has commenced to operate some of its departments thirteen hours a day.

KANSAS CITY, MO.—W. R. Griffin, of Stockton, Kas., has made arrangements with the Cole Motor Car Company, of this city, to handle the Cole 30-40.

PONTIAC, MICH.—With the final installment of machinery in the big A plant of the Flanders Manufacturing Company, the turning out of Flanders electrics will begin shortly.

GRAND RAPIDS, MICH.—Slootmaker Brothers will soon open their new garage on Madison square, at the head of Crawford street, where they are erecting a large cement building.

BOSTON, MASS.—Louis B. Adams, one of the best known newspaper men in New England, has just accepted a position with Harold D. Bornstein, of the Velie Boston branch, in the sales department.

FLINT, MICH.—The production of the 34 and 35 models of the Buick Motor Company for 1912 is steadily increasing. It is expected to increase the average daily output to fifty. The plant is now employing 3500 men.

PHILADELPHIA, PA.—The Pullman Automobile Company of Philadelphia has been formed by Pullman owners who will handle that line in the Quaker City and the surrounding territory, including part of New Jersey and Delaware. Harry Grant is president of the company.

SAN FRANCISCO, CAL.—The Flanders electric is to be handled in Northern California by the Pioneer Automobile Company, which also distributes the Chalmers cars. The company has also taken the agency for the R. C. H. car.

DENVER, COL.—J. A. Fry, for many years branch manager for Apperson Brothers in Chicago, and until recently connected with the Fry & McGill Auto Supply Company, of this city, has assumed the position of manager of the sales department for the Everitt branch in Denver.

FRESNO, CAL.—The San Francisco-Fresno record has been broken by a Warren "30" car, driven by Columbus Hobson of this city. The official time was 5 hours, 42 minutes and 30 seconds, the old record being 7 hours and 17 minutes, which had stood undisturbed for five years.

DENVER, COL.—The Goodyear Tire and Rubber Company has opened a handsome new store at 1562 Broadway. The furniture and fixtures are of white oak and an indirect lighting system makes a brilliant display at night. The branch now has four local and two traveling salesmen.

YORK, PA.—The Pullman Motor Car Company, of this city, announces that, in addition to its line of pleasure cars, it will build taxicabs in the future. The first taxicabs built by the company, a shipment of twenty-five, were sent to the Pullman Taxicab Company, of Philadelphia, last week.

DETROIT, MICH.—Marburg Brothers, importers of the Mea high-tension magneto and S. R. O. ball bearings, have opened a branch office in this city. Mr. Roy J. Taylor, well known in the automobile circles of this vicinity through his connection with manufacturers here, has been appointed manager.

HARVEY, ILL.—The Buda Company has arranged with Brandenburg & Company, located at 1108 South Michigan avenue, Chicago, Ill.; Fifty-seventh street and Broadway, New York City, N. Y., and Ford Building, Detroit, Mich., to sell their products, consisting of motors, transmissions and other parts for automobiles.

EMPIRE, ORE.—Mr. and Mrs. Ralph Barker have successfully completed their strenuous Coast-to-Coast run in their light delivery Reo motor truck. A few months ago Mr. and Mrs. Barker went by train from Empire to their old home in New England, and while there purchased the truck for their return trip. They left Stratham, N. H., August 10, provided with a touring cover forming a regular living room. With this was included a complete camping outfit, which permitted them to pitch their tent whenever and wherever they pleased.

CRIPPLE CREEK, COL.—The Cripple Creek Automobile Company has recently opened a new garage at 140 East Bennett avenue.

COLUMBUS, OHIO—Frank J. Girard, 174 North Fourth street, Columbus, Ohio, has taken the agency for the R. C. H. in 20 counties in central Ohio.

CLEVELAND, OHIO—F. H. Meyers, for many years in the employ of the Standard Welding Company, has been appointed to the office of assistant superintendent.

MILWAUKEE, WIS.—The Gas Power Engineering Company, Third and Wright streets, Milwaukee, has been appointed distributor for the Premier car. The company operates a large garage.

ELMIRA, N. Y.—Incorporation papers for the Elmira Automobile Club have been filed in the County Clerk's office. Incorporators, M. Doyle Marks, Arthur Clinton, Frank E. Robbins, Melvin R. Elis and others.

COLUMBUS, OHIO—The Hudson Sales Company, North Fourth street, Columbus, Ohio, has taken the agency for the Buick for 1912 in Franklin and Licking counties, Ohio. A sub-agency will be established at Newark, Ohio.

COLUMBUS, OHIO—The Cummins Auto Sales Company of 153 North Fourth street, Columbus, Ohio, has taken the central Ohio agency for the K-R-I-T for 1912. The territory includes six counties in the central part of the state.

WASHINGTON, D. C.—A change has been made in the Lozier agency here and the 1912 line of cars will, in the future, be handled by the Lozier Sales Company, of 1315 H street, N. W., this company having been formed exclusively for the purpose.

SAN FRANCISCO, CAL.—The Stanley Steam Car Company has been organized to handle the well-known steam car of that name in Northern California. L. H. Austin and R. C. Bennett, prominent Bakersfield men, are the organizers of the company.

DETROIT, MICH.—J. R. Hall, for five years manager of the Service Department of the eastern district branch of the Lozier Motor Company in New York City, has been appointed to the position of manager of the Service Department of the Lozier Motor Company in this city.

MILWAUKEE, WIS.—The City of Milwaukee, which owns sixteen motor cars, is considering the purchase of six more. Three will be for the use of assistant chiefs of the fire department, two for the health department and one for the consolidated police and fire alarm signal service.

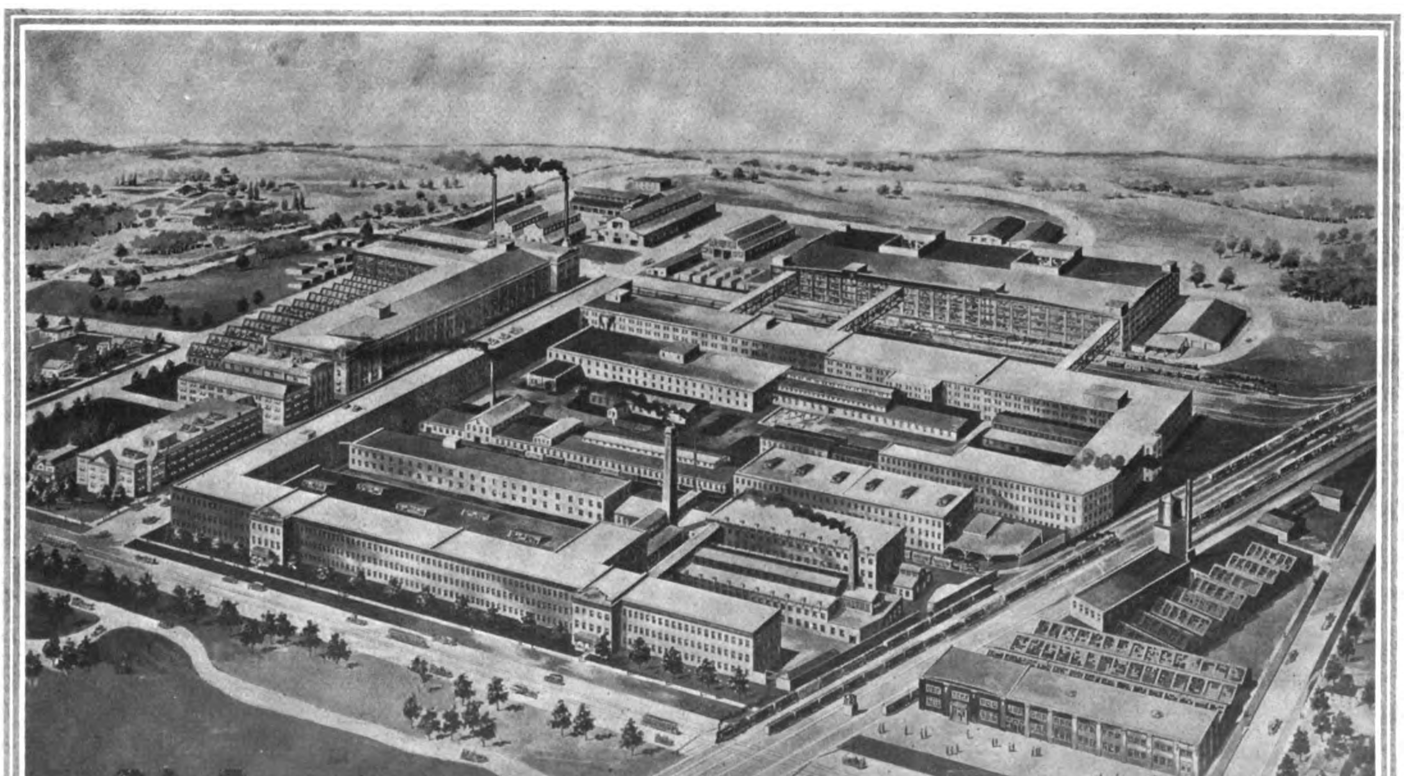
PHILADELPHIA—The Mercer Automobile Company, of Trenton, N. J., has taken the distribution of its cars out of the hands of agents and in future it will be conducted through a branch house which has just been established at 620 North Broad street. W. A. Smith, formerly business and advertising manager of *Automobile Topics*, has been placed in charge as branch manager.

AKRON, OHIO—In a decision handed down recently the circuit court sustained the common pleas court in finding Earl Sprankle of Akron, Ohio, guilty of manslaughter in running down and killing Helen Starr with an automobile which Sprankle was driving. Sprankle was found guilty in the criminal court and sentenced to the Mansfield Reformatory. The case may be carried to the Supreme Court.

INDIANAPOLIS, IND.—The formal opening of the bus service of the Rapid Motor Transit Company in Indianapolis took place on November 1. There are seven cars, six of which are in continual service from 6.30 A. M. to 11.15 P. M. daily, while the seventh is used during the rush hours. Entrance is at the front of the right hand side and the pay-as-you-enter system is employed, the driver collecting fares as passengers enter.

INDIANAPOLIS, IND. — A number of changes have taken place in the local trade. The Case factory sales branch has been moved from North Capitol avenue to 241 Kentucky avenue. A. W. Ellis, city salesman for the Goodyear tire sales branch, has become manager of the Louisville branch. Frank Staley has become Indiana distributor for the R. C. H., with headquarters at 513 North Capitol avenue. A factory sales branch of the Schact Motor Car Co., Cincinnati, O., has been opened at 328-330 North Delaware street.

LOS ANGELES, CAL. — The Alfred C. Stewart Machine Works has disposed of its United States rights to the Detroit Lubricator Company, of Detroit, Mich., which company will be turning out the Stewart Carbureter within the next two or three months.



Bird's-eye view of the enlarged Willys-Overland plant at Toledo, Ohio—new body-building, trimming and paint department building in background

Three-ton Packard truck used in farm work in Connecticut

CLEVELAND, OHIO—The Lozier Motor Company has moved into its new quarters at 6402-4 Euclid avenue.

OMAHA, NEB.—J. A. Longyear, of South Bend, Ind., has recently joined the retail sales force of the Omaha branch of the E-M-F Company.

BOSTON, MASS.—The Malley Motor Vehicle Company, agent for the Warren car, is to handle the Flanders Electric in Boston and vicinity.

BALTIMORE, MD.—The Oakland Sales Company, representatives of the Oakland car and Federal truck in this city, has moved to its new quarters on East Chase street.

SAN FRANCISCO, CAL.—The Pioneer Automobile Company has taken the agency for the Flanders Electric car. R. H. Morris will be in charge of the company's electrical department.

BOSTON, MASS.—F. L. Sanford has joined the sales force of the Henley-Kimball company and has been given charge of the wholesale department for outside territory on Hudson cars.

NEW YORK CITY—The Mitchell-Lewis Motor Company, of Racine, Wis., has opened a branch house at 1855 Broadway and a new service building on Fifty-first street, west of Broadway.

SYRACUSE, N. Y.—I. W. Reid has resigned as comptroller of the Franklin Automobile Company. His plans for the future are undecided. B. E. Snyder, head accountant, has assumed Mr. Reid's duties.

BOSTON, MASS.—The new Alco branch is now located in Copley Square with George M. Hudson as manager and has leased quarters in the big Shoe &·Leather building in Cambridge for a service department.

MONTREAL, CAN.—The Canada Auto & Taxi Company, of this city, announces that, to comply with the ever-increasing demand for taxicabs, they have decided to reduce their fares by one-half during business hours.

CLINTON, ONT.—The town of Clinton voted to-day to sell a partly equipped plant and to give a fixed assessment to the Clinton Motor Car Company, which consists of Toronto capitalists and local manufacturers.

BOSTON, MASS.—The Selden car and the Mais truck, formerly handled in this city by W. S. Jameson on Boylston street, are now being marketed by R. L. & H. L. Smith & Company with offices at 1008 Commonwealth avenue.

BOSTON, MASS.—The J. W. Maguire Company, agent for the Pierce Arrow car in eastern Massachusetts, has secured a lease of the premises next door to its present site, giving it one of the largest salesrooms on Boylston street.

NEW YORK CITY—The various articles of automobile clothing used in connection with the illustrations for "Comfort in Winter Driving," in our issue of November 2, were from the establishment of the Auto Supply Company, 1789 Broadway, New York City.

SYRACUSE, N. Y.—The Franklin Automobile Company's local business will be handled hereafter at the factory in South Geddes street. More ample display facilities are afforded, while the repair work can be better handled in the factory repair department.

UTICA, N. Y.—The Oneida Garage Company will soon erect one of the finest garages in this section of the State at 215 Park avenue. The officers of the company are Frank Bowen, president; H. T. Powell, secretary and treasurer, and George A. McCracken, general manager.

DETROIT, MICH.—Hal Reifenberg, manager of the Warner Instrument Company's branch house at Kansas City, Mo., has been put in charge of the company's branch house in this city, succeeding A. S. Koto, who has resigned. Mr. Reifenberg's successor has not yet been announced.

LOUISVILLE, KY.—Arthur W. Ellis, of Indianapolis, is the new manager of the local branch of the Goodyear Tire & Rubber Company. He succeeds Robert B. Harbison, who has resigned. James B. Williams, of Harrodsburg, has been chosen to fill the position of office manager, formerly held by Robert Grabill.

CLEVELAND, OHIO—Mr. Frank L. Sessions has been appointed to the office of superintendent of the Standard Welding Company. Mr. Sessions is a graduate of Worcester Polytechnic Institute, 1889, a member of the American Society of Mechanical Engineers and of the American Society of Electrical Engineers.

FRESNO, CAL.—The Warren-Detroit car, which won the silver cup in the recent endurance run from San Francisco to Los Angeles and return, also broke the road record between San Francisco and Fresno. The official time was 5 hours, 42 minutes and 30 seconds, the former record was 7 hours and 17 minutes.

NEW YORK CITY—J. R. Hall, for five years manager of the service department of the Eastern district branch of the Lozier Motor Company here, has been appointed manager of the service department of the Lozier Motor Company of Detroit, Mich. Mr. Hall has been identified with the Lozier interests for more than twenty years.

ATLANTA, GA.—So vigorous has been the competition for desirable situations for automobile agencies in Atlanta that they are becoming hard to find. The Locomobile Company of America has not as yet been able to locate its Atlanta Branch and is still occupying desk room at 230 Peachtree street. The company will soon open its own place.

INDIANAPOLIS, IND.—Kark Feilcke, chief designer and engineer of the Motor Car Manufacturing Company of this city, sailed from New York last week to attend the Olympia show in London, thence proceeding to the Continent, where he will investigate any new ideas of the European manufacturers. He will return early in January to attend the New York show.

GREENWICH, CONN.—Conyers Farm covers 1,600 acres in this State and a small tract in New York State. It is famous for its apples, of which this year's harvest totaled 3,500 barrels. The work about the farm is so heavy and continuous that a 3-ton Packard truck is in constant use doing the heavy hauling. Much of the work of the truck consists in transporting the farm products to this place, fully 7 miles distant. During portions of the year the truck is kept in constant service for 20 hours out of the 24, and it has been proven time and again that it can make three trips while the horse-drawn teams used on the farm are making one.

WASHINGTON, D. C.—Colonel George Schutt has returned from a 4,500-mile trip to Omaha, Neb.

MILWAUKEE, WIS.—The Spring Bearing Truck Company has increased its capital stock from $10,000 to $20,000 to care for extensions of the business.

HAZLETON, B. C.—After a gruelling trip, replete with adventure, the Flanders Pacific Highway pathfinder successfully completed the rail-blazing run from Seattle, Wash., to this city.

BERLIN, GERMANY—Because cattle do not mind a little noise like the tooting of an automobile horn a German manufacturer has added folding whips to the equipment of his cars.

INDIANAPOLIS, IND.—Charles Lacy, of Buffalo, has taken charge of the repair shop at the local branch of the Buick Motor Company. Mr. Lacy has had great experience in automobile repair work in the East.

WASHINGTON, D. C.—The Lozier Sales Company has been formed to handle the Lozier here. W. M. Giesey, formerly of Pittsburg, will be the manager. The salesroom has been located at 1315 H street, N. W.

WASHINGTON, D. C.—The Pope Automobile Company, agent for the Pope-Hartford and the Columbus Electric, has been appointed agent for the Marathon in the District of Columbia, Maryland, Virginia and West Virginia.

WASHINGTON, D. C.—Miller Brothers, one of the oldest motor cars firms here, and who have handled the Ford and Velie for a number of years, have relinquished the agency for the latter make. Several firms are negotiating for the Velie agency.

RICHMOND, VA.—The Virginia Taxicab Service Company, of this city, has instituted suit for damages to the sum of $45,000 in the Law and Equity Court against the Sultan Motor Company and the Otis Elevator Company. No declarations have as yet been filed.

SAN FRANCISCO, CAL.—Two new automobile agencies have invaded San Francisco the past week, the Bergdoll and Colby machines. Ben R. Savanah has the agency for Northern California on these two new cars and will shortly appoint sub-agents throughout the interior of California.

MILWAUKEE, WIS.—The Milwaukee and Wisconsin agency for the Packard, held by Welch Brothers Motor Car Company, has been supplanted by a direct factory branch which will be located in the present Packard garage. O. G. Heffinger, sales manager for the Welch Brothers company, becomes general manager, and the technical management continues in the hands of H. W. Liddle. R. C. Chidester will be sales manager.

STEVENS POINT, WIS.—The Central Wisconsin Motor Show was held here by the Auto Sales Company to celebrate the opening of its large garage. The company handles the Cadillac, E-M-F, Flanders Buick, Stoddard-Dayton, Overland and Rambler. Dr. J. W. Bischoff, a well-known physician and one of the earliest motorists of the State, is at the head of the concern. The Mayor and other notables made addresses each night.

Automobile Incorporations

AUTOMOBILES AND PARTS

BOSTON, MASS.—Vera Motor Car Co.; capital, $60,000; to manufacture automobiles. Incorporators: G. M. Polani, A. M. Sweeney.

BRADFORD, PA.—Bradford Auto Exchange; to make automobiles and parts. Incorporators: F. H. Reed, J. I. Holmes, F. H. Deagan, S. L. Tibbitts, F. D. Gallop.

BUFFALO, N. Y.—International Automobile League Tire & Rubber Co.; capital, $1,000,000; to manufacture tire casings and inner tubes.

BROOKLYN, N. Y.—Finlay Automobile Co.; capital, $10,000; to sell automobiles. Incorporators: William Finlay, Joseph School, Ernest Finlay.

DETROIT, MICH.—Detroit Bi-Car Co.; capital, $100,000; to manufacture automobiles. Incorporators John J. Chapin, Alfred Roseroot, John J. Berkery, Frank J. Gorman.

EVANSVILLE, IND.—F. W. McNeely & Co.; capital, $25,000; to deal in automobiles. Incorporators: Chester Rankin, F. W. McNeely, Alice McNeely.

ERIE, PA.—Stirling Brothers Co.; capital, $15,000; to sell automobiles. Incorporators: Alex Stirling, John Stirling.

FREDERICKSBURG, VA.—Fredericksburg Motor Co., Inc.; capital, $10,000; to conduct a general automobile business. Incorporators: L. R. Colbert, Alvin T. Embrey, H. C. Biscoe.

KNOXVILLE, TENN.—Stewart Automobile Co.: to deal in motor cars. Incorporators: R. G. Stewart, E. F. Ferry, L. Lemay, Mrs. S. Stewart, Mrs. Nellie Blankenship.

NEW CASTLE, IND.—Whitesides Commercial Car Co.; capital, $31,250; to manufacture freight automobiles and parts. Incorporators: F. N. Whitesides, O. S. Saffert, O. O. Carpenter.

NEW YORK CITY.—Hatch Oil Engine Co.; capital, $100,000; to manufacture engines and machinery. Incorporators: C. W. Hatch, W. P. Hatch, Jr., A. Anderson.

NEW YORK CITY.—International Motor Service Association; capital, $100,000: to manufacture automobiles. Incorporators: Wm. H. Brearley, Walter W. Friend, Irene A. Monsees.

PORTLAND, ME.—Hamlin-Foster Co.; capital, $100,000; to manufacture automobiles. Incorporators: Arthur D. Hamlin, Albert S. Ventrea, Charles C. Briggs.

RIDGE, N. J.—Stark Auto Co.; capital, $10.000: to deal in automobiles. Incorporators: Jacob H. Stark, Harry S. Stark, Robert A. Sibbald, Frank O. Mittag.

SANDUSKY, OHIO.—Sandusky Auto Parts Co.; increased capital stock to $500,000.

WILMINGTON, DEL.—Eastman Motor Truck Co.; $25,000; to manufacture freight automobiles. Incorporators: J. H. Sheidis, C. E. Semmes, H. G. Eastburn.

WOODSTOCK, ONT.—Woodstock Automobile Mfg. Co., Ltd.; capital, $50,000; to build automobiles. Incorporators: Alexander C. Applebaum, Herbert H. Thorpe, H. F. Greene.

AUTOMOBILE GARAGES AND ACCESSORIES

AKRON, OHIO.—Diagonal Block Tire Co.; capital, $25,000; to make automobile and motorcycle tires and other rubber goods. Incorporators: J. A. Swinehart, W. R. Talbot, Frank R. Talbot, A. L. Siegrist, W. H. Graham.

BROOKLYN, N. Y.—Agotaras Garage Co.; capital, $10,000; to sell, repair and store motor vehicles. Incorporators: Wm. R. Hoffman, Leonora Klinger, John Bahr.

BUFFALO, N. Y.—Frontier Tire & Rubber Co.; capital, $250,000; to manufacture pneumatic tires. Incorporators: George B. North, Howard N. Gill, Franklin D. L. Stowe.

CLEVELAND, OHIO.—Cleveland Welding & Mfg. Co.; capital, $150,000; to manufacture rims and other welded products. Incorporators: E. I. Heinesohn and others.

CHICAGO, ILL.—General Auto & Repairing Co.; capital, $25,000; to conduct a general garage and taxicab business. Incorporators: W. R. Potter, George H. Davis, Frank H. T. Potter.

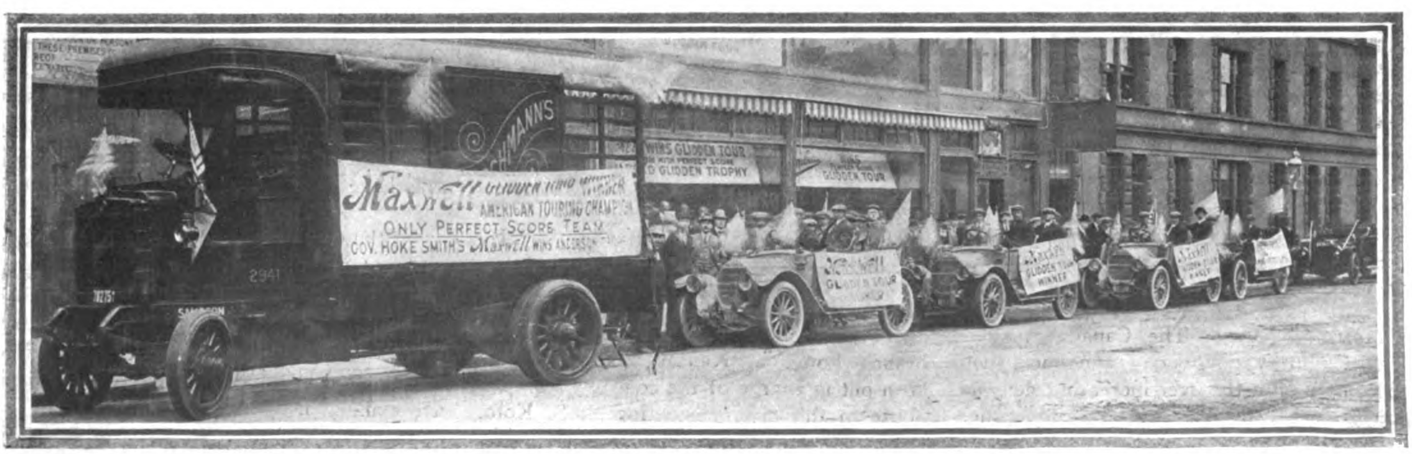
NEW ORLEANS, LA.—Hercules Tire Co.; capital, $50,000; to manufacture tires and rubber goods. Incorporators: J. M. Underwood, Sam J. Connell and others.

NEW YORK CITY.—City Taxicab Co.; capital, $10.000; to conduct a taxicab business. Incorporators: Arthur J. Smith, Wm. Oakford, F. M. Oakford.

NEW YORK CITY.—G. & Accessory Co.; capital, $100,000; to make and sell automobile supplies. Incorporators: F. D. Glover, J. G. Stuart, J. Z. Lowe, Jr.

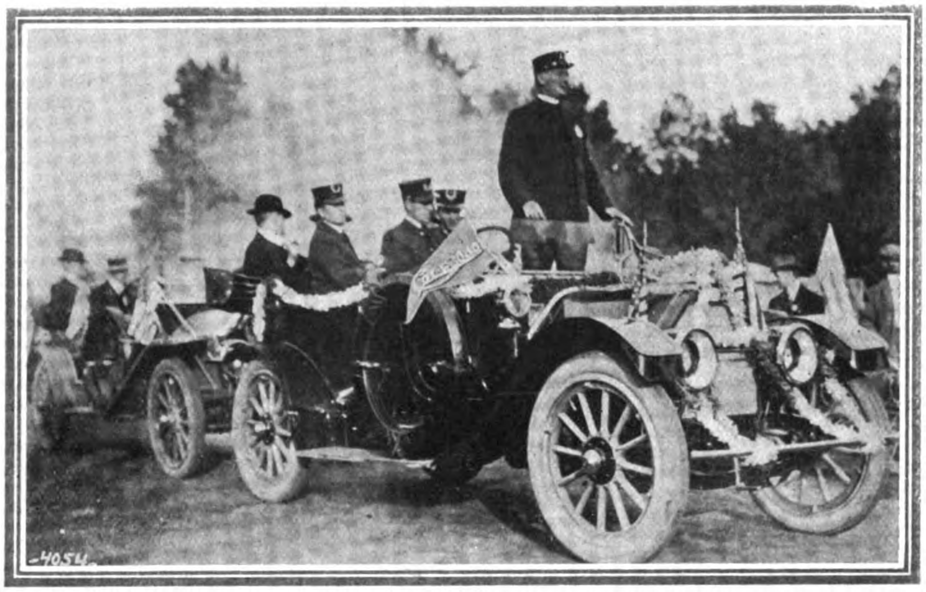
NEW YORK CITY.—The Service, Inc.; capital, $100,000; to conduct a general agency relative to automobile trade, collections, etc. Incorporators: D. M. Hooks, T. B. Nisbet, F. C. Carr.

NEW YORK CITY.—Teven Garage Co.; capital, $10,000; to conduct a garage business. Incorporators: Joseph C. Graveur, Martha Graveur, Ross Teven.



Ending of the parade in honor of the Maxwell Glidden winner, at the United States Motor Company building, New York City

OF INTEREST to the INDUSTRY



Atlanta police with their new Cole service car meet Gliddenites

ATLANTA, GA.—The police of Fulton County, in which this city is located, have long felt the need of an automobile in their work. Two weeks ago a 1912 Cole 30-40 car was purchased for them and, by a happy coincidence, the first duty it was called upon to perform was to meet the incoming Glidden Tour and guide it into and through Atlanta.

AKRON, OHIO.—A. G. Partridge has been appointed assistant sales manager of the Firestone Tire & Rubber Company.

FORT WAYNE, IND.—At the annual meeting of the stockholders of the Ideal Auto Company it was unanimously voted to increase the capital stock from $50,000 to $100,000.

PITTSBURG, PA.—Reports received here from the capitals of many States show that in two years the number of women drivers of automobiles have increased more than three times over.

COLUMBUS, OHIO.—The contract has been awarded for a large addition to the plant of the John W. Brown Manufacturing Company of Columbus, Ohio, makers of automobile lamps and other accessories.

SUMTER, S. C.—L. A. Prince, of the Ohio Motor Car Company, of Cincinnati, Ohio, has taken the managership of the Ohio Sales Company of South Carolina. He will operate a vulcanizing plant in connection with this.

RIO DE JANEIRO, BRAZIL—More than a dozen large manufacturers of American motor cars have sent representatives with demonstrating machines to this city in the past month to take advantage of the great boom in the automobile industry.

MILWAUKEE, WIS.—David Van Alstyne, vice-president in charge of the manufacturing department of the Allis-Chalmers Company, has sent in his resignation, to take effect November 15. C. E. Search, formerly Mr. Van Alstyne's assistant, has been appointed works manager.

BIRMINGHAM, ALA.—The H. W. Johns-Manville Company have found it necessary, owing to increasing business, to change the location of their office from 1220 Empire Building to 606 Chamber of Commerce Building. The office will continue under the management of W. H. Fleming.

NEW YORK CITY—The balance of trade in motor cars continues to grow in favor of the United States. Besides the gain in exports, in the first eight months of 1911 there were imported 608 cars valued at $1,312,969, against 723 cars valued at $1,443,871 in the corresponding period of the preceding year.

COLUMBUS, OHIO.—T. A. Sawyer has purchased the business of the Monnett Brass Company, located at 62 1-2 East Spring street, Columbus, Ohio, and has changed the name to that of the Sawyer Auto Brass & Specialty Company. The concern will continue the business of making accessories and parts for motor cars.

INDIANAPOLIS, IND.—Directors of the Whitesides Commercial Car Co., recently reorganized, and which is moving from Franklin, Ind., to Newcastle, Ind., have elected the following officers: President, O. W. Saffell; vice-president, F. M. Whitesides; secretary and general manager, C. W. Boyd, and treasurer and factory manager, J. W. Prigg.

MUNCIE, IND.—Thomas J. Heller, formerly sales manager of the Standard Roller Bearing Company, has joined the forces of the Warner Gear Company as Eastern factory representative, with headquarters at Glenwood avenue and Second street, Philadelphia. Mr. Heller will handle the Eastern sales end of the company, whose product comprises pleasure and commercial car transmissions, steering gears, control levers, clutches and differentials. Mr. Heller is well known to the automobile trade.

DETROIT, MICH.—The Lavinge steering gear, formerly manufactured by the Lavinge Mfg. Co., has been taken over into a new corporation, known as the Lavinge Gear Co. The new company has been organized with a capital of $100,000, with offices at Detroit and Milwaukee. In addition to the Detroit plant, they will operate a larger plant for the manufacture of the steering gear exclusively at Corliss, Wis., a suburb of Milwaukee. Joseph P. Lavinge, inventor and designer of the steering gear, will remain with the company as chief engineer.

NEW YORK CITY—Montgomery Hallowell, general advertising manager of the United States Motor Company, has resigned to join the forces of the H. E. Lesan Advertising Agency, where he will assist in the handling of the United States Motor Company advertising and in the broadening work of the Lesan Agency, a work for which, by long experience, he is eminently qualified. Gridley Adams has been appointed to succeed him. Mr. Adams has been advertising manager of the Stoddard-Dayton division of the United States Motor Company and is well known in the advertising field.

COLUMBUS, OHIO—The Union Sales Company of Columbus, Ohio, is backing the organization of what will be styled the Union Motor Car Company, which will manufacture a new line of motor cars to be known as the Union "25." The work of manufacturing has been started at the plant of the Dunlap Engineering Company, 1436 Parsons avenue. J. W. O'Brien, of Nashville, Tenn., who is at the head of the Union Sales Company, announces that contracts have been signed for 5,000 parts and it is proposed to build at least 200 cars during the coming season. Only one model will be made and that will be a two-seated runabout which will sell for $650 or $700, equipped with windshield, lamps, speedometer, top, generator and trunk. The offices of the company are located at 61 East Spring street and the marketing of the product will be done by the Union Sales Company.

PATENTS GONE TO ISSUE

INTERNAL COMBUSTION ENGINE—In which flow of gases is regulated by an oscillating valve.

3. The patent (Fig. 1) covers the combination with a cylinder having an inlet and an exhaust port, of an oscillating valve pivoted therein at one end of its body portion, controlling both the exhaust and inlet ports, and means for producing oscillation of said valve.

No. 1,007,491—To Robert A. Reynolds, Detroit, Mich. Granted October 31, 1911; filed March 15, 1909.

Rotary Engine—Combining the principles of cylinder and rotary piston.

5. This engine contains a cylinder in which operates a rotary piston. In the latter is slidably mounted a device which has diametrically opposite blades. An abutment is slidably mounted in a cylinder and co-acts with the piston, it being urged inwardly by a spring. A cam projects into the cylinder and is disposed in the path of the blades, causing one blade to move inwardly and the opposite blade to move outwardly. Means are provided for conveying a charge into the cylinder on one side of the abutment, while on its opposite side means for igniting are located. As the blade passes and pushes the abument outwardly a charge may be admitted into the cylinder under pressure.

No. 1,007,100—Bert H. Harris, Goldhill, Oregon. Granted October 31, 1911; filed May 6, 1910.

Acetylene Lamp—A combination of acetylene generator and light.

1. This patent (Fig. 2) refers to the combination of an acetylene lamp with a carbide reservoir having a cap on which is mounted a water receptacle, with a burner extending from the cap and a block of fibrous material covering the inner end of the burner. To the under side of a metallic plate is secured a section of cork adapted to close the opening of the carbide reservoir with the plate resting upon the edge of the reservoir opening. Cork and plate have a number of conical openings for the passage of gas from the reservoir to the acetylene burner, fibrous material being loosely packed in the openings.

No. 1,007,374—To Anton H. Mollman, Jr., Hillsboro, Ill. Granted October 31, 1911; filed December 31, 1910.

Clutch—Containing in its make-up a bearing and races.

5. In this clutch (Fig. 3) a bearing race with revoluble bearing members is interposed between the driving and the driven members, wedging members being adapted to be projected against the bearing members to wedge the same in their race. A ball is mounted over each of the wedging members and axially movable clutch members are provided which, when moved together, exert pressure on the balls, whereby the wedging members operate to wedge the revoluble bearing membrs in their race.

No. 1,007,139—To Bertram H. Penn, London, England. Granted October 31, 1911; filed October 8, 1910.

Carbureter—Spreader members are used to obtain good mixing effect.

3. This carbureter (Fig. 4) comprises a casing with an inlet of the bottom and an outlet at the top. To control the outflow of mixture from the casing a throttle is provided and a supply connection extends to the casing and is provided with a valve seat and spreader member. With the valve seat co-operates a valve member to which is connected a movable spreader member co-operating with the fixed spreader member. Thus an annular outlet is formed between the two members and means are provided for yieldingly supporting the valve member and the movable spreader so as to allow the same to be opened by the suction through the casing. The opening movement of the valve is limited. Means are provided to operate the throttle and at the same time limit the movement of the valve, thereby allowing increased opening of both valve and throttle.

No. 1,007,659—To Merrill B. Rice, Los Angeles, Cal. Granted October 31, 1911; filed October 25, 1910.

Vehicle Tire—A pneumatic tire in which the rubber canvas body is reinforced by an armor fabric.

The tire protected by this patent comprises a casing, a reinforcing for this casing, including a canvas fabric body suitably disposed and incorporated within the casing, an armor fabric imbedded in the casing and extending into the heel portions of the same and disposed above the reinforcement mentioned. Hooked portions are formed on the termination of the side portions of the armor fabric, and a second armor is embedded and vulcanized in the tire casing and disposed above the first armor fabric, the second armor being V-shaped in cross-section with inclined sides formed thereby to ward off any sharp point which might pierce the casing, and hooked portions formed at the termination of the sides to securely anchor the second armor.

No. 1,007,018—To Harry Wilson and Carl Guder, McKeesport, Pa. Granted October 24, 1911; filed July 12, 1911.

Pipe Joint—Being of a universal ball-and-socket type.

This joint compromises two tubular sockets, one of which fits into the other. Into the center of axis of one socket a hub is mounted, and co-axial with it another hub in the other socket. One of the hubs carries a bolt secured against longitudinal displacement in the hub. The bolt has a head and around it is fitted a sleeve which bears with a spherical edge against a spherical depression of the hub carrying the bolt. The sleeve has a spherical depression for the bolt head to rest upon and is connected to hub not carrying the bolt.

No. 1,007,362—By Johann Koenig, Riga, Russia. Granted October 31, 1911; filed May 27, 1911.

Newest Ideas Among the Accessories

Start-Lite Illumination

THE system of lighting a car which is illustrated in Fig. 3 is made so as to relieve the driver of all trouble in lighting the lamps. It is made by the Start-Lite Company, of 1502 Michigan avenue, Chicago, Ill. In this system gas is led through suitable connections and piping to all the lamps and lights on the automobile. The control mechanism for the entire system is installed on the dash of the car, and gas may be admitted to one lamp or all of them at a time, according to the desire of the operator. On the same controller is also installed a switch for each headlight, sidelight and taillamp, and by switching on the current, a spark is produced in the gap of the sparker located above the burner of the respective lamp. The figure brings out clearly all the details of the wiring and piping systems serving the purpose of illumination on the automobile, and the installation of the system is simple enough to be undertaken by any mechanic. All the acetylene is taken from one tank, and all the current required comes from a battery, both being preferably installed upon the running boards of the car.

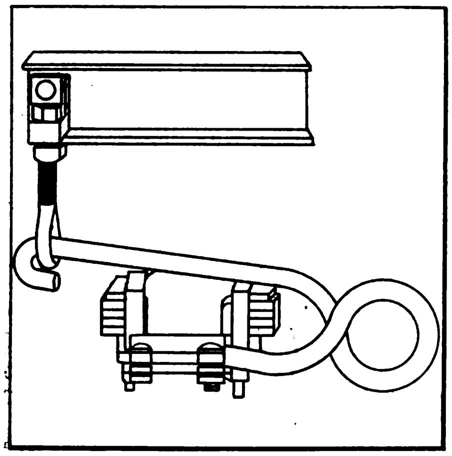

Fig. 1—View of the Ideal Shock Absorber

Ideal Shock Absorber

The Ideal type of shock absorber, Figs. 1 and 2, consists of two elements, as may be seen in Fig. 1. One is a steel loop attached to the chassis frame by means of a bolt and nuts, while the other is a one-piece oil-tempered-steel spring, which is coiled at its middle portion and bent to form a hook at one end. This hook engages the loop aforementioned, while the other end, which is only half as far from the spring coil, is securely fixed to the axle of the car.

In its normal state the shock absorber is in the position shown by the full lines in Fig. 2. Here the two arms of the absorber spring are in an almost parallel position. If an automobile thus equipped hits a thank-ye-mar'm, the Ideal spring prevents the car springs from coming together and hitting the axle, by assuming the position B. At the same time, a great deal of the energy transmitted to the axle by the shock is taken up by changing the position of the absorber spring, which thus assists the ordinary springs in their business. The opposite effect of the absorber spring is used in hitting a bump. Here the inertia of the spring causes it to take on the position C, thereby absorbing most of the shock which otherwise would be transmitted to the body and the passengers occupying the same, causing discomfort and deterioration.

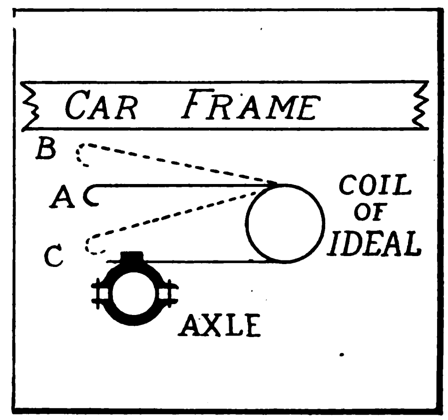

Fig. 2—Principle and operation of Ideal

While the use of shock absorbers on the rear axle of a car is becoming quite common practice, the application of Ideal springs to the front of the automobile softens the effects of the road inequalities otherwise affecting the power plant and front portion of the chassis, thus relieving these portions of severe strains and adding to the life of the machine as a whole. The Ideal shock absorber springs, which are sold at a very moderate price, are guaranteed against breakage for 5 years. They are handled by the American Sales Company, of 1882 Mount Elliott avenue, Detroit, Mich.

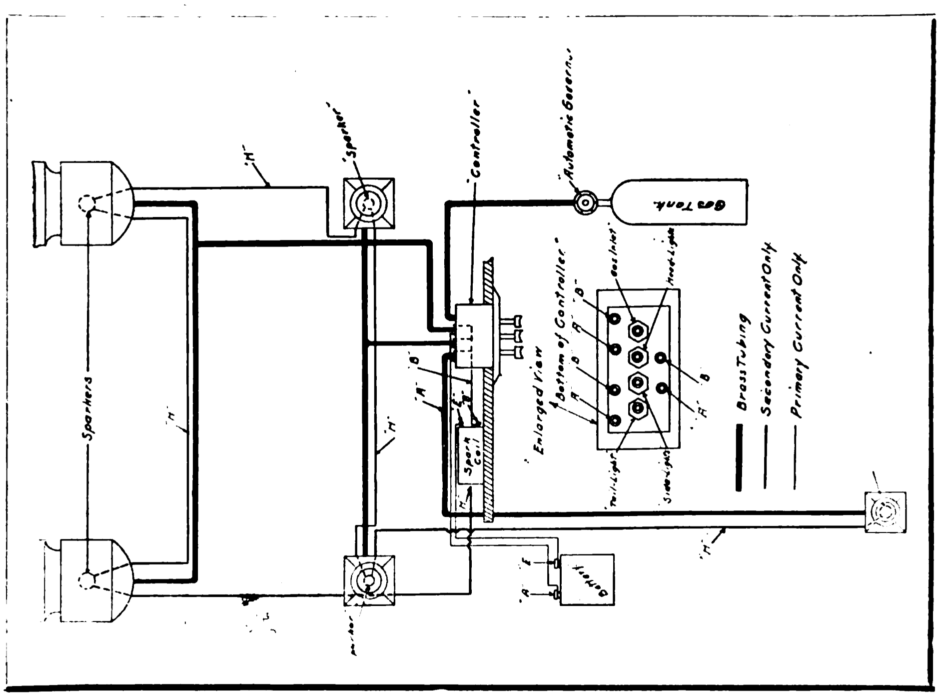

Fig. 3—Wiring and piping diagram of Start-Lite system

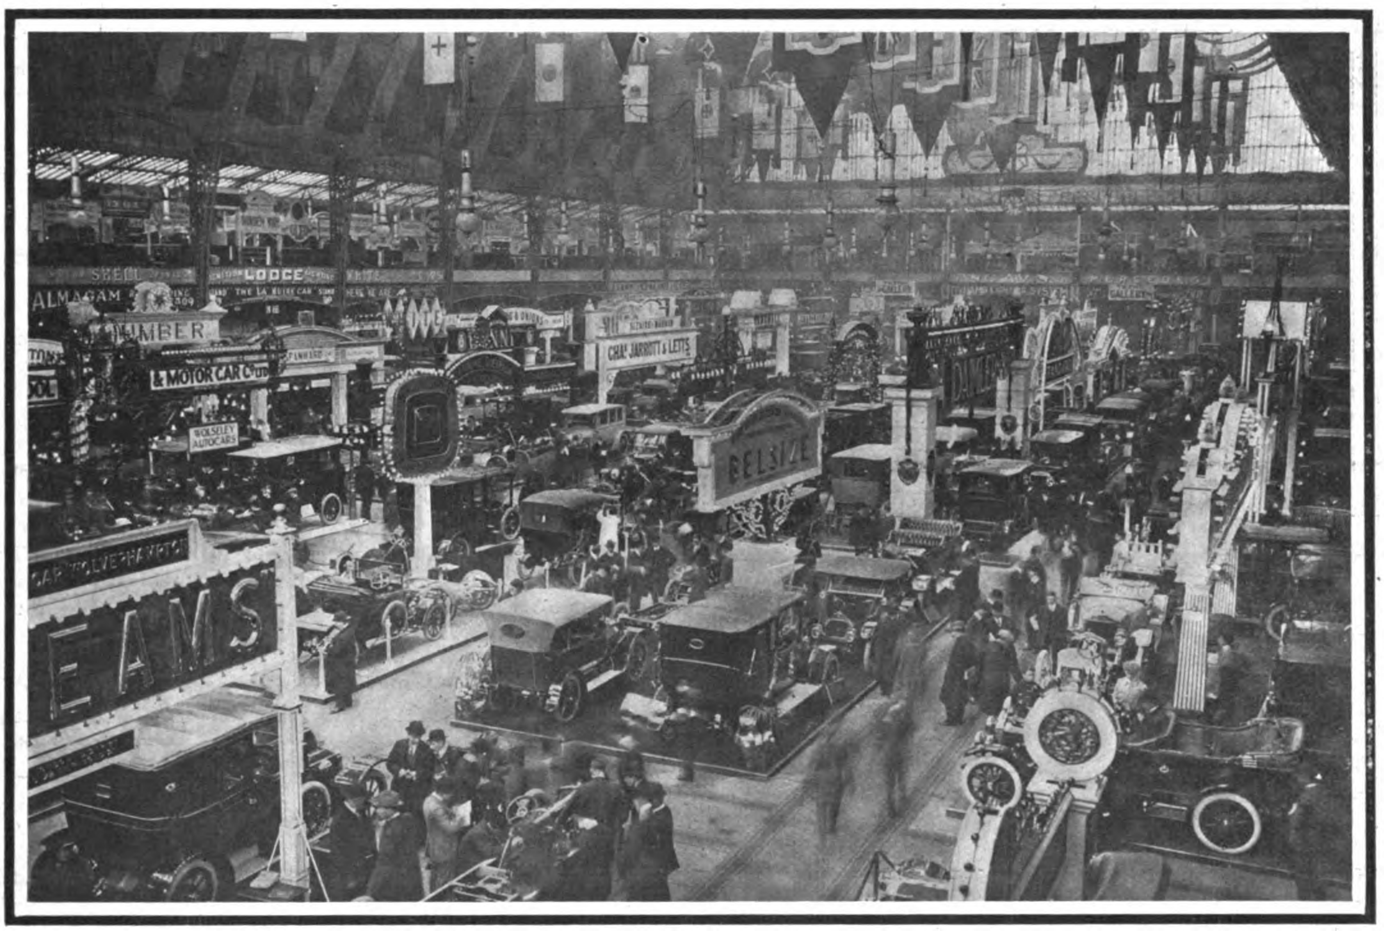
Wright Spark Plug

The N. Y. Mica & Manufacturing Company, whose factory is located at Auburn, N. Y., are marketing a new type of Wright spark plug. The claims of principal importance of this new plug made by the manufacturer thereof are the strength and heat-resisting qualities of the porcelain insulation. Where the porcelain core comes in contact with the hex and the asbestos bushings the shoulders of the porcelain core are cut with a round sweep so as to eliminate the danger of cracking at the narrowest point in the porcelain.

VOL. XXV NEW YORK—THURSDAY, NOVEMBER 16, 1911—CHICAGO NO. 20

THE AUTOMOBILE

Many New Features at Olympia Show



GENERAL VIEW OF THE INTERIOR OF THE TENTH ANNUAL AUTOMOBILE SHOW AT OLYMPIA

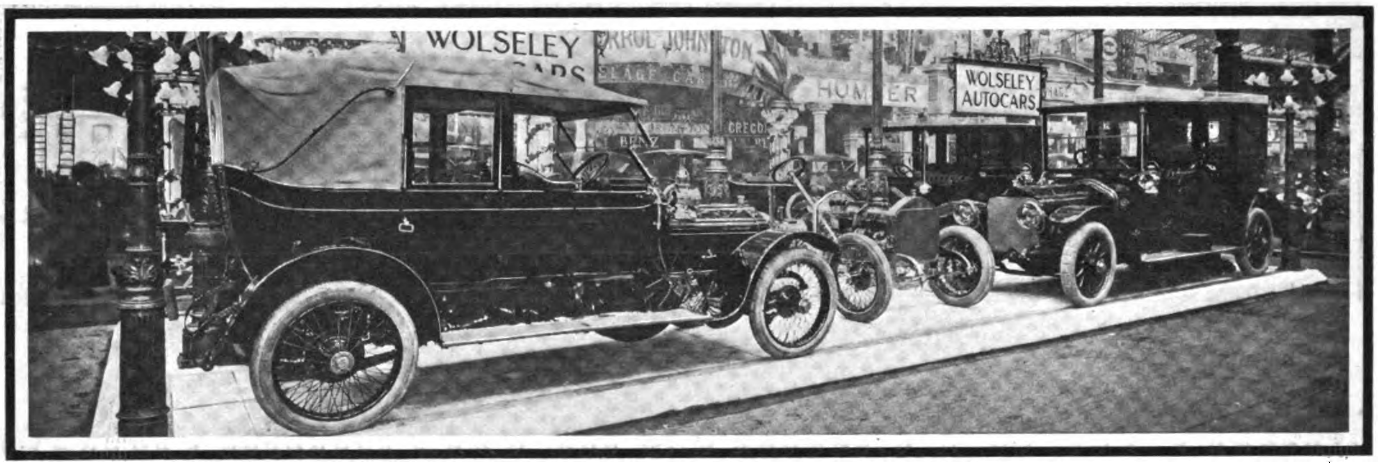
LONDON, Nov. 3.—John Bull opened his tenth annual automobile exhibition to-day at Olympia, a hall almost as cramped as the Grand Central Palace, without that building's advantage of central location. Britain's free trade policy has made the London exhibition the only international one in the world, for in addition to the home products it brings together the best from France, Germany and Italy, and a certain amount of American representation. It would perhaps be more correct to say that it attempts to bring together the automobile product of the whole world, for, the hall being altogether too small for requirements, numbers of makes are crowded out, and among those having applied in vain for admission are at least half a dozen American concerns most recently introduced to the European market.

As was to be expected, the question of obtaining a substitute for poppet-valves is being given a large amount of attention by the engineers of all European countries, and out of the mass of schemes submitted by enthusiastic inventors to level-headed business managers three have survived. In the background are many more almost ripe for public presentation, and many of them will doubtless come forth at no distant date.

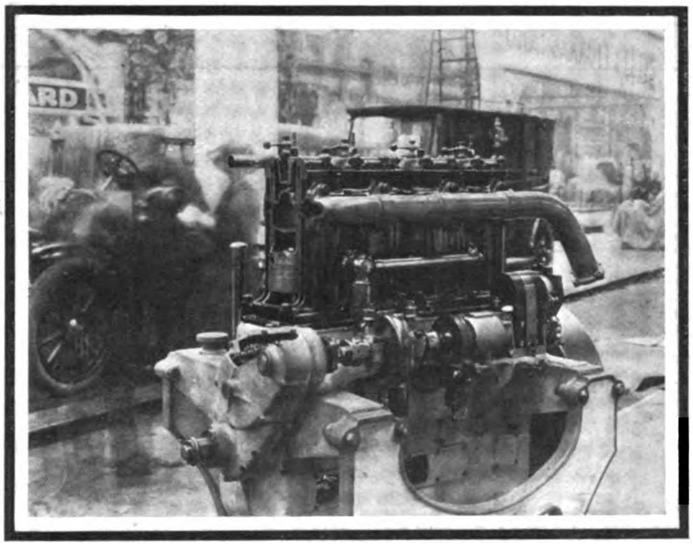
The three new systems are the Henriot rotary valve adopted by Darracq for one model of car only; the single sleeve valve taken up by the Argyll Company, and a rotary valve by the Itala concern. It is worth noting that in all three cases the rotary or sleeve-valve motors are being produced concurrently with poppet-valve types.

The Henriot is the most familiar of the three, for it has been exhibited by the inventor at earlier shows in Paris and demonstrated by him on cars during the past two years.

The Argyll motor has a single sleeve with a combined rotary and reciprocating motion within the cylinder. In other words



The Wolseley stand at Olympia was representative of one of Britain's foremost factories



New Silent Knight Minerva motor with magneto and water pump at side

it describes an ellipse during two complete revolutions of the crankshaft. The idea is one which has been seized upon by a number of inventors, for Da Costa, in Paris, produced a motor of this type, but abandoned it for a single rotary sleeve after experiencing considerable difficulty in finding a good driving system. Also, it is a strange coincidence that while the Argyll people were working on their sleeve-valve motor, the Piccard-Pictet engineers in Geneva were at work on an almost identical design. When the Swiss applied for patents in England they found that they had been forestalled by Argyll, and when the Scotchmen made application on the Continent they discovered someone already in possession. The outcome was a compromise, each firm having rights in its own country.

The single sleeve of the Argyll is about 1-8-inch thick, naturally ground inside and out, and carries at its base a lug to which is attached a vertically pivoted pin and a small face block. At right angles to the pin is a spindle having a bearing in a gear wheel, this letter meshing with a pinion on a lay shaft driven at motor speed by means of a silent chain in the fore portion of the engine base. The inventor has made use of five ports in the sleeve and six in the cylinder, one of the port sleeves doing service for both an inlet and an exhaust port in the cylinder. The valve ports are not cut rectangular, but to a duplicated curve in order to assure the quickest possible opening and closing. As in the Knight system, a separate head is employed; it carries a broad junk ring and a narrow piston ring, all of them being pinned to prevent turning.

Two important features are that at the moment of explosion all the ports in the sleeve are protected behind the extended head; further, after the passage of the exhaust gases the ports in the sleeves immediately pass to a waterjacketed portion of the cylinder walls. Lubrication has been thoroughly provided for by means of a force-feed system to all main bearings, troughs for the connecting-rod ends, and separate leads to each of the sleeve-operating mechanisms. The motor, which has a 25-horsepower rating, has its cylinders cast in two pairs.

The new Itala, which is a four-cylinder of 105 by 150 mm. bore and stroke, makes use of one pair of rotary valves for the four cylinders, each valve of course performing the necessary functions for the two cylinders cast together. On each casting is an outstanding cylindrical casing having an internal diameter of 4 inches, and within each of these cylindrical casings are two ports 3/4-inch wide by 3 inches in length through which the charge passes to the respective cylinders and the spent gases are liberated. The distributor valve is provided with three sets of rings, one at the base, one set on the upper portion of the body of the distributor and the third set on the end of the upper extension. The distributor valves revolve at one-quarter motor speed, the ports in the distributor being duplicated so that alternate inlet charges and alternate exhaust charges come in contact with a given port in the rotary valve. The ports in the distributor are so arranged as to lead the exhaust gases from the cylinder port up the rotary valve and out through the head into the exhaust manifold. The fresh gases pass in from the base of the valve directly into the combustion chamber. The exhaust ports in the rotary valve are cut about 30 per cent. greater area than the intake ports. As difficulties might be expected with overheating in a valve fulfilling the two functions, the designer has very cleverly cored the valve itself so as to provide as efficient a circulation of water through it as around the cylinder walls. Driving of the rotary valves is obtained by means of two vertical spindles—one for each valve and for each pair of cylinders—with spiral gearing from a horizontal shaft in the position of the usual camshaft. It is from this shaft that drive is transmitted to a central transverse shaft having the water pump on the right and the magneto on the left. Provision has been made for a possible seizure of the rotary by the use of a safety coupling with undercut tongues which can be sheared off in case of any unusual resistance. On the base of the driving spindle is an Oldham coupling having a brass ring with two full and two under-cut dogs, these latter capable of being sheared if seizure takes place. A fresh ring can be fitted into position in place of the damaged one.

The Knight Motor Is Prominent

The Knight motor has made further progress, for while being continued by the Daimler Company for all models, Panhard now produces a smaller type of 80 by 130 mm. bore and stroke, the B. S. A. Company has taken it up for a cheap car, the Rover Company employs it, and the Deasy concern is making use of it for one model; and Giradot, of C. G. V. fame, is to use it in 2,000 cars for the coming season.

Important among the new tendencies is the unit type of construction for motor, clutch and gearbox, generally combined with three-point suspensions. The idea is old, but it is one which has never caught on in Europe until the present season. Now the lead has been taken by the Panhard, which has built the new Knight chassis on these lines, the motor being attached to the frame members by two hangers, and the rear suspension being to a transverse frame member. Another important convert is the De Dion, which has adopted unit construction and three-point suspension for two new light cars having one and two cylinders respectively. Several less important firms have taken up this type of construction.

Monobloc Cylinders Are the Rule

The tendency is more and more towards monobloc casting for large motors having four or six cylinders. There appeared to be only one example of a motor with separately cast cylinders with a five-bearing crankshaft, this being on a little known English car. In the matter of monobloc casting the Continental manufacturers have certainly secured a lead on their English rivals; indeed clean-cut appearance and general accessibility is far more pronounced on the generality of the foreign than on the average home product. Combined with this tendency towards monobloc castings is the use of thermo-syphon water circulation for models of the largest size. It has been common to use thermo-syphon for the small cars and pump circulation for motors having 4 inches bore or more. Now, however, it is being extended to cars of unlimited power, and in addition to the Renault, which has always led in this direction, thermo-syphon cooling is being adopted by the Darracq, Charron, and Delage for motors developing as high as 60 horse-power.

The coming system of lubrication in Europe is of the force-feed type, the base of the crank chamber forming an oil tank from which the lubricant is drawn by a pump and delivered to the main bearings and through the bored crankshaft to the connecting-rod ends. At least a score of firms could be mentioned which have taken up this system with various detail modifications. Apparently difficulty has been experienced in certain cases in forcing oil right through a two-bearing crankshaft for a four-cylinder motor, or from the center bearings of a six-cylinder motor to the more distant connecting-rod ends. This has led, in the case of the Chenard-Walker motors, to the bolting of light aluminum casings having a semicircular oil lead onto the two inner webs of the crankshaft; thus the shaft is only bored through from the two main bearings to the two outer connecting-rods, the flow from these two points being through the bolted-on oil leads. Where a three-bearing crankshaft is employed the favorite method is similar to that employed on the new Panhard-Knight, where the oil is delivered direct to the three bearings and distributed through the shaft from the end bearings to the two outer connecting-rod ends, and from the center bearing to the two central connecting-rod ends. The only other system which is receiving any considerable amount of favor is force-feed to the main bearings and troughs with dippers for the connecting-rod ends. It avoids the necessity of boring the mainshaft, but it is a system which will doubtless have to give way before force-feed throughout. A few makers have retained splash on the plea of simplicity, and on the Charron the flow from the tank on the dashboard is connected up to the accelerator pedal, so that the amount of drip is in proportion to the extent that the accelerator pedal is depressed. The arrangement is neatly carried out, for the oil tank is built into the same casing as the gasoline tank on the dash, and the interconnecting mechanism is within a dummy portion of the tank on the extreme right-hand side.

Chain drive for the camshaft has not yet ousted pinions, but it appears to be in a fair way of doing so, for one or two chains are being used on nearly half the motors exhibited. It has now been found, however, that provision must be made for taking up slack, and this is being done either by means of an idler pinion mounted on an eccentric or by means of an eccentric mounting for the magneto shaft, where the motor has one chain only for cam and magneto shafts.

There is little that is new in ignition devices, the high-tension magneto reigning supreme. Even the preference shown by the English for a secondary ignition as a standby has now disappeared, apparently being satisfied by the dual ignition on one set of plugs. A beginning is shown towards the adoption of dual high-tension ignition firing two plugs simultaneously in one cylinder. This has been adopted for some time on racing cars, but is only just beginning to make its appearance on touring models.

The three-speed gearboxes which were formerly fitted on most of the small and medium powered cars are having to give place to four speeds with gate change. There are very few cars, now, of whatever power, which are not provided with four forward speeds, while those French manufacturers who clung to the straight-through type of sector have been obliged to fit a selective type to meet the requirements of the English market.

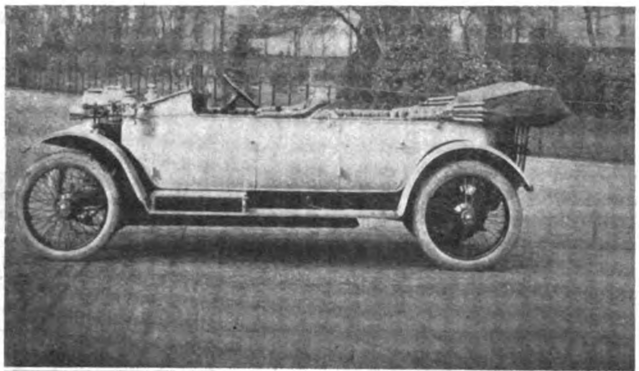
A Review of the Design

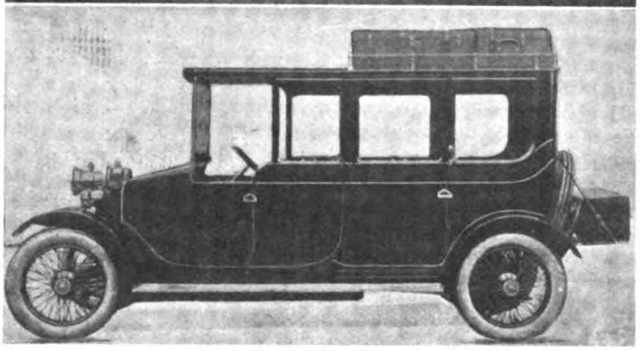
A GREAT number of American firms are not to be seen within the big hall or its annex, owing to the fact that their membership is not yet one year old. The United International Motors, Ltd., which has started on a big scale to sell Maxwell and Stoddard cars in the United Kingdom, has found itself outside the pale. Amongst others the Cameron air-cooled car, the Mitchell, the Hudson, the Krit, the Flanders, the E. M. F. have also failed to get a place in the exhibition. The chief American cars on show are the White, the Cadillac, the Overland, the Buick, the Hupmobile and the Ford, to which perhaps one or two may be added after a closer inspection of all the stands. Of course an attempt has been made to make capital out of this exclusion of so many American agents, the suggestion being made that the society has desired to throw obstacles in the way of those who are putting on the English market cars of a price with which English manufacturers find it difficult to compete. That there is no foundation for this rumor is evident from the fact that English people have also been excluded, together with even such an important firm as the Zenith Carbureter Company, which is supplying carbureters to a very great number of leading manufacturers.

This year at Olympia there is scarcely a single car of merit that has not abandoned spur gear for driving the accessories of the engine.

The magneto and water pump, if these are not driven directly off the camshaft, are operated by silent chains or worm-gear. In fact, this is the most noticeable tendency in the whole of the exhibition. One firm has gone even to the length of introducing a gearbox in which the changes of speed are obtained by silent chains. This firm is the Maudslay, which has always been remarkable for the pains it has taken to give great accessibility as well as science. It is a firm with fine traditions, having been well known in the forties and fifties of the last century for its steam engines, examples of which may be found in mechanical museums all over the world.

There seems little unanimity about the worm-driven back axle which was brought to the front last year. It has been used by Lanchester and by Dennis for a number of years, but they were alone until the Show of 1910, when the Daimler Company with several others decided to adopt it. This year it has found some new adherents, but one or two of the firms who spoke so highly of it last year are now quietly dropping it. Its great merits were said to be silence and ease of fitting. The bevel gear is certainly inclined to produce chattering besides

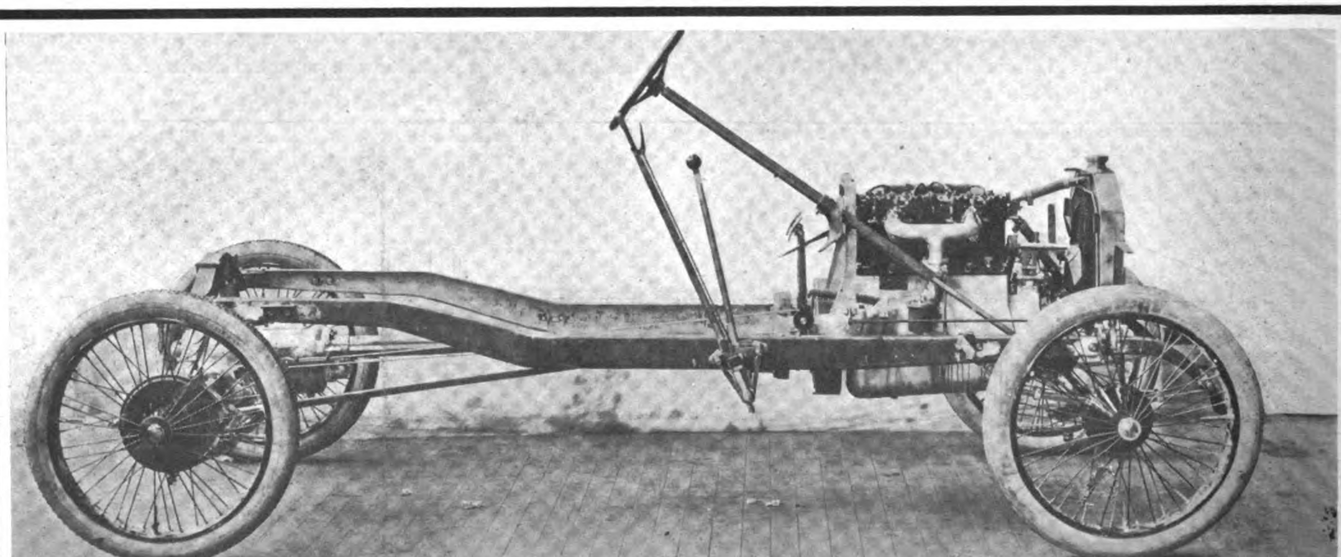




Two types of body construction shown at Olympia by the Lanchester Company

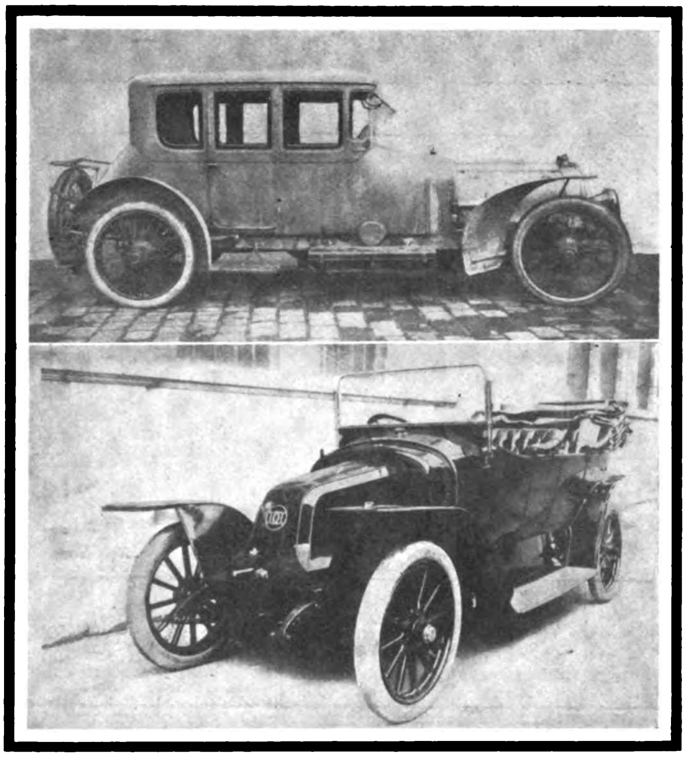
Notably among those having made this change is the Delaunay-Belleville Company. Chain driven gearboxes have been promised and indeed are used in France by Aries, and in London by the General Omnibus Company, but they have made their appearance on only two makes of touring cars, both of British construction. Final drive by worm gearing remains an English idea, at least half a dozen firms having taken it up, whereas in France Darracq is its only producer. Even in this case the change has been made more with a view to meeting English than French requirements.

A novelty in brake construction is shown by the La Buire Company in the form of a foot-brake on an extension of the propeller shaft. The shaft passes right through the differential housing and it is on the projecting extremity that the additional brake is mounted. The Argyll Company, on its new sleeve-valve model, brakes on all four wheels diagonally, a rear wheel on one side and a front wheel on the opposite side being operated together.



Chassis of the low-priced car with Knight motor put out by the B. S. A. Company

Tendencies at Olympia



Delaunay-Belleville with inside-steering body
Darracq touring car with rotary valve motor

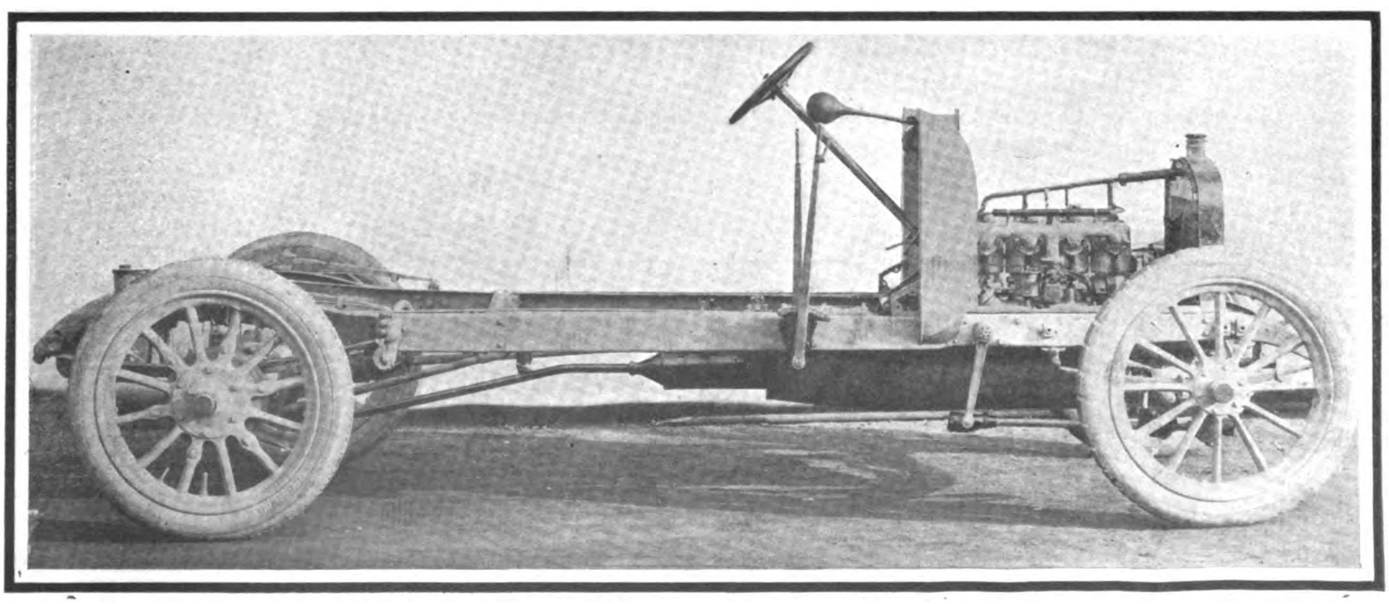
humming, whereas the worm drive is indeed really silent. It is now said by one or two manufacturers that the bevel drive is far superior in hilly districts, and they advise customers not to have worm drive if the car is likely to be called upon to do very much hill climbing. In this year's exhibition there are firms using both worm drive and bevel drive.

Front brakes appear to be losing favor, after having been introduced with a rush about two years ago. The fault seems to lie not with the principle, but with the design, because the firms that have the best designs are still fitting the front brakes. The Argyll has introduced them on its new 25-horsepower sleeve-valve model, and in this case the front and rear brakes are diagonally cross-connected for the purpose of preventing the tendency towards side slipping which is sometimes shown by cars with front wheel brakes. In the matter of brakes the best innovation stands to the credit of the La Buire car, on which the drum of the foot-brake is found at the rear of the differential casing. It is mounted on an extension of the bevel shaft, and of course in this position no brake-stresses are transmitted through the universal joints. This seems a very logical position for the front brake to occupy.

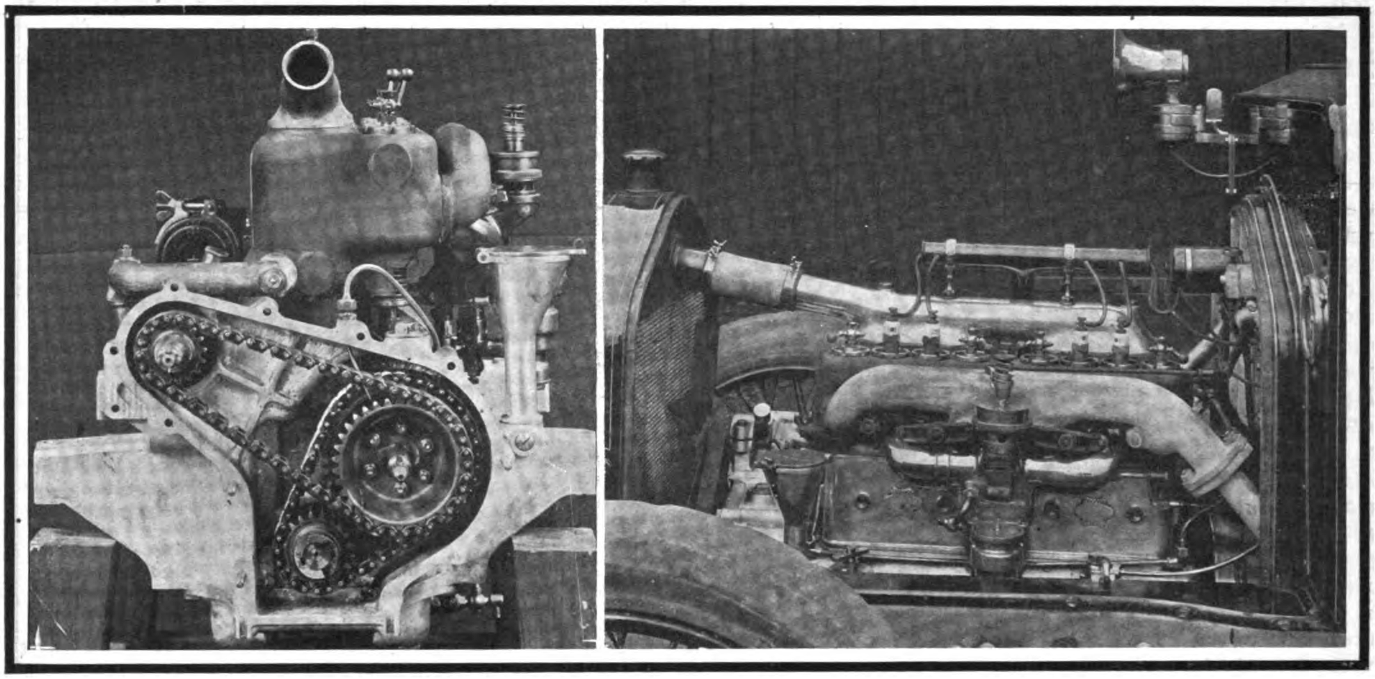
Six-cylinder motors have settled down on a rational basis. They are supplied by most firms if a car of fairly high power is demanded. The only firm which was manufacturing a really small-powered six-cylinder car has dropped the model for this year. Delaunay-Belleville has a six-cylinder car of a nominal 10 horsepower, but this year its smallest six-cylinder model is nominally 19 horsepower. The fashion set by the Rolls-Royce to cast the cylinders in two sets of three is now being copied by the best makers of six-cylinder cars. Exactly what the benefit is does not appear to be very clear. Quite a new idea is the vibration damper to be found on the Daimler and Deasy cars. At certain critical speeds the engine tends to cause noticeable vibration, the cause of which has been discovered to be the length of the crankshaft. The addition of the damper, which is something in the nature of a slipping clutch arrangement, has been found to keep the engine running smoothly over its whole range of speed. These dampers are fitted at the forward end of the crankshaft.

It may be stated that the long-stroke engine is finding favor. The longest strokes are found in the cars produced by firms which have had racing experience. This feature now has additional importance in England owing to the sliding scale of taxation being based upon the horsepower rating, which is reckoned entirely by cylinder bore. The classes that have been introduced for taxation are now plainly governing the choice of cylinder bores. Thus one finds 11.9-horsepower cars in fair numbers, these just escaping the 12-horsepower tax. Similarly, a big number of 15.9-horsepower models have been introduced to escape the 16-horsepower tax. This is a point which American manufacturers should bear in mind. The assembling of engine clutch and gearbox in one unit has found a few more adherents, and the enclosed valve gear has become much more popular.

Only the Cadillac car has been added to the list of models which fit a self-starter. The Cadillac system is at present unique, being operated electrically, whereas all other models of self-starters operate by compressed air. Some firms like the Belleville, Seat and Enfield now make provision for the fitting of compressed-air self-starters, but are not supplying the parts as standard equipment. In addition to a service of compressed air for tire inflation, as well as for engine starting,



Chassis of the 15-horsepower Austin, showing separate cylinders and cased-in change-speed bracket



Two views of the Wolseley 16-20-horsepower engine, one showing the gear cover removed

one or two manufacturers are arranging for the use of pneumatic jacks.

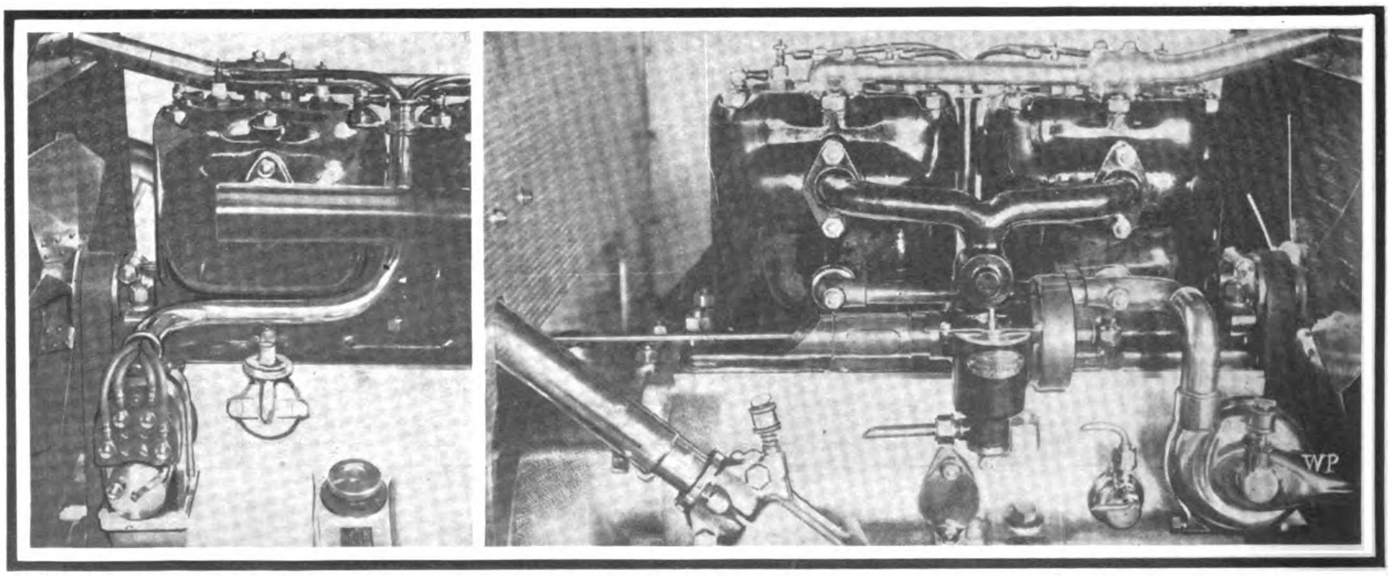
On some of the cheaper cars wire wheels of the fixed pattern have been adopted. A very noticeable movement towards four-speed gearboxes on cars of small and moderate power is seen at this show. And if one adds that still a few more manufacturers have gone over to the plate clutch one completes a review of the general tendencies that are to be noted in the design of cars at the Olympia exhibition.

Some Features of the Small Panhard

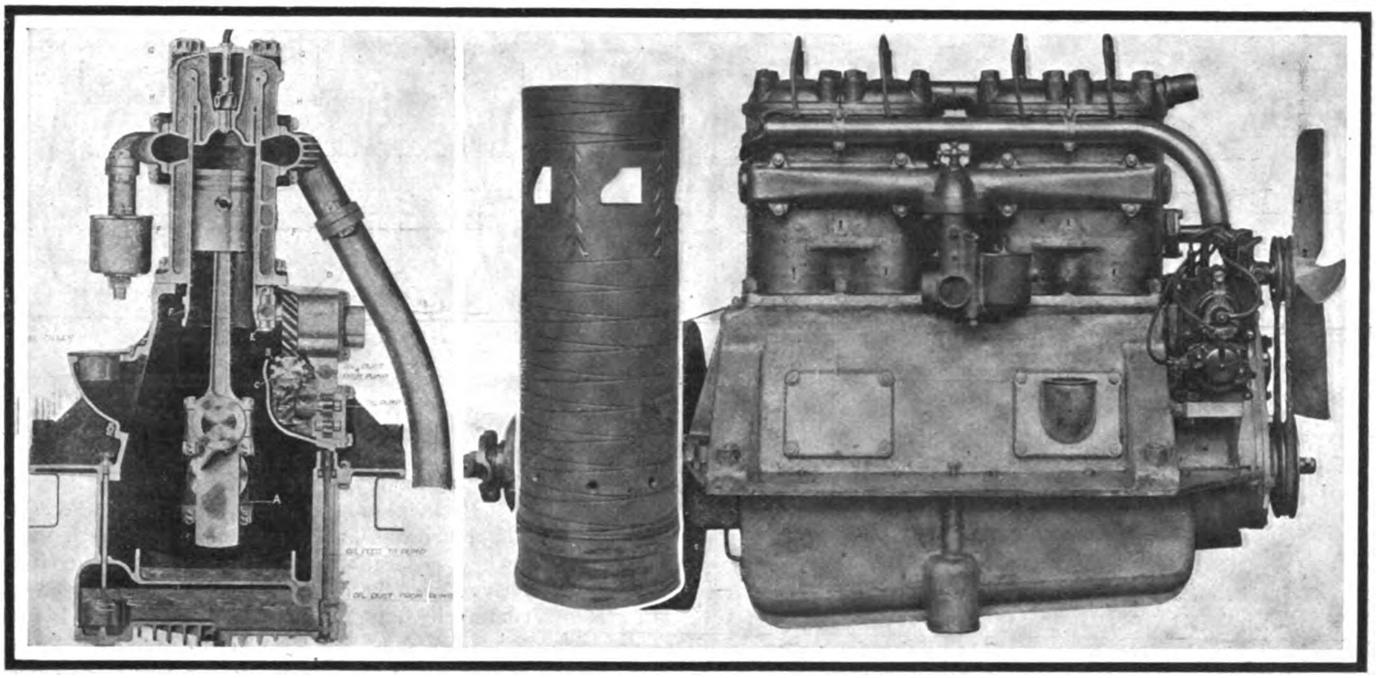
For the 1912 season the Panhard Levassor Company will produce two models with the Knight sleeve-valve motor, the four-cylinder of 100 by 140 and a smaller model having four cylinders of 80 by 130 millimeters (3.1 by 5.1 ins.) This is the most popular size of motor in Europe at the present time, and with the introduction of this model almost half the Panhard output will consist of Knight motors. A poppet-valve motor of the same bore is already manufactured, but the new Knight is not intended to replace this, and is indeed an entirely new chassis, departing in many important respects from previous Panhard design. The motor has its four cylinders cast in pairs, and is on the unit principle, the motor, clutch and gearbox forming a single bloc with three-point suspension. The crankshaft is carried on three plain bearings, while the chain, instead of being in a separate housing at the front of the motor, is now removed to the rear.

As on the larger Knight motor, a transverse shaft at the front of the motor drives the magneto on the left and the water pump on the right. An important change has been made in the lubrication of the motor; instead of a circulating system, the base of the crank chamber forms an oil sump from which the lubricant is drawn by a pump working off the eccentric shaft and delivered to the three main bearings, then through the bored shaft to the connecting-rod ends. The shaft is not bored throughout, but the oil delivered to the central bearing is carried through to two connecting-rod ends; the lead from the end bearings is through to the outer connecting-rod ends.

The clutch and gearset are within a separate housing independent of the crank chamber, yet bolted to it in order to form one bloc, the whole unit being attached to the frame by two hangers about level with the rear of the second cylinder and



Showing some of the details of the small Panhard engine with Knight sleeve valves



Vertical section and side view of the Argyll single-sleeve motor

at the rear of the gearbox to a double channel-section transverse member. Hitherto Panhard clutches have been either cone or multiple discs; on this model a plate clutch is used, the surfaces being fibre and steel. The gearbox gives four speeds with two sliding sets of gears operated by a straight-through sector and a cam mechanism within the gearbox, as on some of the firm's trucks. Clutch and gear housing come under the footboards, and on the top of the housing are two large inspection plates, each one held down by a single screw. Final drive is by propeller shaft with bevel gearing, the shaft being carried in a torque tube, and the tube stayed triangularly from a point one-third from the rear to a point under the spring seating. The rear axle is also a new design, the housing being formed of two tapered tubes bolted to the halves of the vertically divided differential housing. The rear axle is not trussed in any way. The abolition of the independent gearbox has carried with it the disappearance of the transmission brake. All braking is now done on the rear wheels, there being two expanding shoes side by side within each drum, one pair being operated by pedal and the other by the side lever with connection made by steel ribbons guided through fiber rollers.

The Argyll Single-Sleeve Valve Engine

The main difference between the Argyll and the Knight motors is that the former uses one sleeve and the latter two.

The crankshaft, connecting rod and piston are of the usual type; the special features of the engine being the single-sleeve valve with its specially shaped ports, the corresponding ports in the cylinder, and the mechanism for operating this valve so as to control the opening and closing of the admission and exhaust ports. As usual in four-stroke engines the valve is operated at half the engine speed.

In the cylinder there are six ports, three on each side, those on one side being exhaust ports and those on the other admission ports. In the sleeve there are five ports, two being admission and two exhaust, the odd port acting alternately as an admission and exhaust port. The cylinder is closed at the top end by means of the head, which may be described as a fixed piston, this piston being the same diameter as the motor piston and projecting into the cylinder so that between the cylinder wall and the head an annular space is formed in which the sleeve works.

Lubricating system on Panhard 15-horsepower with Knight motor

The peculiar twisting motion of the sleeve of the Argyll motor may be likened to screwing a plug into a plain hole, where, by twisting the plug round, and at the same time pushing it in, it can be entered with comparative ease. On account of the twisting motion, which reduces the resistance, the sleeve never comes to rest, but is continually in motion in one direction; there is thus no dead center involving a sudden reversal of direction of travel. The twisting movement which allows of the sleeve ascending and descending by different paths, provides for a natural lubricating motion, spreading the oil over the entire surfaces with which which the sleeves come in contact. It is impossible for a sleeve to seize, as even if the lubricating oil were cut off entirely the first thing to seize would be a piston or a bearing, and so efficient and reliable has the method of lubrication proved to be that this state of affairs is impossible except through gross carelessness or neglect.

When, after years of service have so worn the pistons and the insides of the sleeves that they require renewing, all that is necessary is a new sleeve valve and a standard piston, and as the sleeve and the parts therein are ground and cut accurately to standard, no fitting is required.

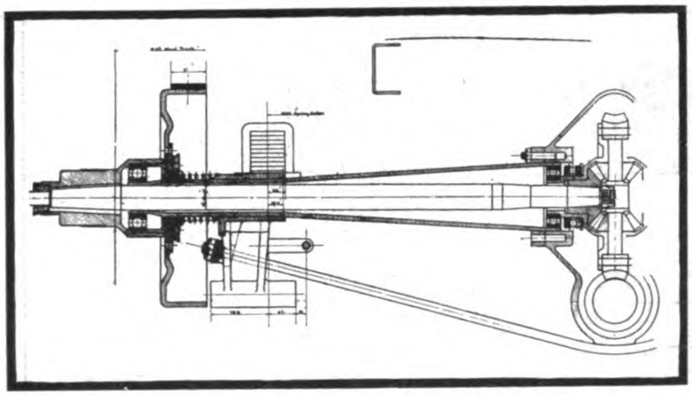
Long Stroke and Four Speeds Popular in England

The ratio of bore to stroke of British-built cars varies widely. Few of the makers appear to favor a cylinder diameter of less than 3 inches. Some of them, however, are putting out models around 12 horsepower with bores slightly under this figure. For motors of this size, the tendency is toward a stroke around 4 3-4 inches, although the 10-horsepower Austin, with a 2 1-2-inch bore, has a stroke of 3 1-2 inches. Most of the leading models have the long-stroke motor, as already stated. The ratio is seen to be considerably greater than 1, in most cases, with the exception of a single model—that of the New Engine Motor Company. The leading makers seem to lean toward a ratio of about 1.5 to 1, or even a larger figure, in their models having bores between 3 and 4 inches. Above this diameter, the ratio is lower, being around 1.25 to 1. The Sunbeam six, rated at from 25 to 30 horsepower, has the distinction of being the only model in the list with a stroke of 6 inches or over, its stroke being 6.31 inches with the small bore of 3.56 inches.

Few of the cars listed can be put in the high-power class; the Napier makers, however, exhibited a six-cylinder, 65-horsepower machine with a bore of 4 inches and a 5-inch stroke; ratio, 1.25.

Although the worm drive appears to be losing ground, a great number of the models still cling to it, among these being the Daimler, Maudslay and Rover. Others make it an optional feature, while still others specify bevel drive on all machines of their make. In the matter of numbers, at least, the latter appears to have the best of it, but it cannot be denied that there are points in favor of the former.

Together with the movement for longer stroke motors, is that for four-speed drive. Many of the older makers hold tenaciously to the three-speed type, but it would seem that they must



Rear axle arrangement used on the 20 and 30-horsepower Daimlers

all come to it in time. Conspicuous among those who still adhere to the three-speed drive are the Rolls Royce, Ltd., the Daimler Motor Co., Ltd., and S. F. Edge, Ltd. (manufacturer of the Napier). The writer is not familiar with the arguments for or against either drive, but, from the number of makers using the four-speed type, it is evidently fast gaining ground.

The following table will show at a glance the principal mechanical data of the better-known English cars:

NAME	No. Cyl.	Bore Inches	Stroke Inches	Bore Stroke Ratio	Horse-power	Drive	Speeds

Average Prices of British Cars

In 1911 there were seven one-cylinder cars manufactured and sold at prices varying from $735 to $1,305, the average price being $1,010. For 1912 there are only six one-cylinder cars listed, and at a price of $650 to $1,175, the average price being $835.

As regards two-cylinder cars, seven models were listed at a price of $850 to $1,365, the average working out at $1,160 while for 1912 the number has increased to nine, ranging in price from $750 to $1,325, or an average of $1,110 each.

With regard to four-cylinder cars, there is a considerable increase in the number of medium-powered four-cylinder cars to be placed on the market selling up to $1,750: for example in 1911 there were nineteen four-cylinder models, varying in price from $1,415 to $1,750, the average price working out at $1,555 each. This number for 1912 has increased to thirty-three models, varying in price from $855 to $1,700, the average price being $1,285.

The cheapest four-cylinder car to be put on the market for 1912 is a 10-horsepower R. A. C. rating, sold complete at $875, while the highest power car is one of 24.8 horsepower, sold complete at $1,725.

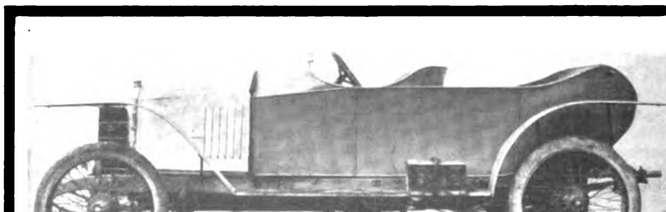
The Belsize company, a firm which has hitherto been one of the leaders in the lower-price cars, has introduced a new model, 11.8 horsepower, which will be sold complete at $1,050.

The Arrol-Johnston company is introducing a car of similar power at $1,425 complete, while the Daimler company is introducing a car of 13.9 horsepower, sold as the B. S. A. for the price of $1,625 complete, or chassis price $1,250. Thus British manufacturers are producing lower-priced cars than has hitherto been the rule.

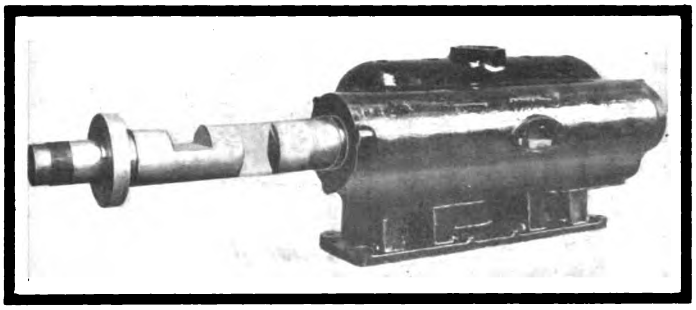
There appears to be no diminution in the number of British manufacturers; on the contrary the number of manufacturers has increased during the present year. Neither is there any diminution in the number of models produced, which shows an increase of about 10 per cent. The six-cylinder car maintains somewhat of a stationary position as regards numbers, and some twenty-eight models will be found listed in this class, the cheapest vehicle being the 29.4 horsepower Vulcan and the 36.2 horsepower Belsize, which are listed at $1,975 for the chassis, while the most expensive are the 59.9-horsepower Napier at $4,975 and the 48.6-horsepower Wolseley at $5,000.

British Trade Statistics

During the year 1910, the value of the imports of cars, chassis and parts totalled $25,673,830, of which re-exports were made to the value of $2,610,860. The exports of British manufactured goods amounted to $13,027,625, the actual number of cars manu-



Vauxhall car with a new design of semi-racing body



Cylinder casting of new Darracq with rotary valve partly withdrawn

factured by the British makers being between 18,000 and 19,000.

The past season has been an extremely good one for the British manufacturer, and all the established firms have been able to keep their factories running at full pressures, and statistics which are made up to the end of September 30, 1911, go to show that the trade of 1911 will be considerably in excess of the trade of 1910, and that the prospects for 1912 are indeed favorable.

It is not quite easy to compute the actual number of cars built in Great Britain, but a fair estimate can be made by taking the increase in the registration, as given by the various county and borough county returns. In 1910 the total number of vehicles, excluding motor cycles, registered in Great Britain, was:

Motor cars	124,860
Commercial vehicles	7,406
Total	132,266

The corresponding figures for 1909 were 107,934, thus showing an increase in the number of cars registered of 24,332 in 1910; as a matter of fact, the actual number will be rather less; owing to the fact that lapsed registrations are not always accounted for.

In 1910, 2,995 cars and chassis were exported to British possessions, and 1,124 to foreign countries, of which 77 came from the United States.

The total imports for the 9 months to September 30, 1911, amount to $22,825,965. The re-exports are valued at $2,129,590, and the exports of British goods at $10,600,000, which show a very large percentage of increase over the same period in 1910.

The imports comprised 10,125 vehicles and chassis, as compared with 8,352 in 1910, and there is no doubt that a considerable percentage of the increase represents American cars.

From the figures given above it will be seen that in 1910, 1,101 cars were imported from America, and there is evidence that that number will be more than doubled during the present year, as for the 7 months ending July the number of cars imported from the United States was 1,875, having a total value of $1,635,-995, the average price of the cars imported being $885 each, whereas the average price of the total imports is $1,305 and the average for 1910, $1,430.

Although the threatened invasion of American cars has not yet to any great extent affected the English manufacturers, there is evidence that the manufacturers here are preparing to meet competition. It is quite evident that the imports of American cars to this country are of a type which have not been hitherto constructed by British makers, and little or no attempt has yet been made to produce a similar type in this country.

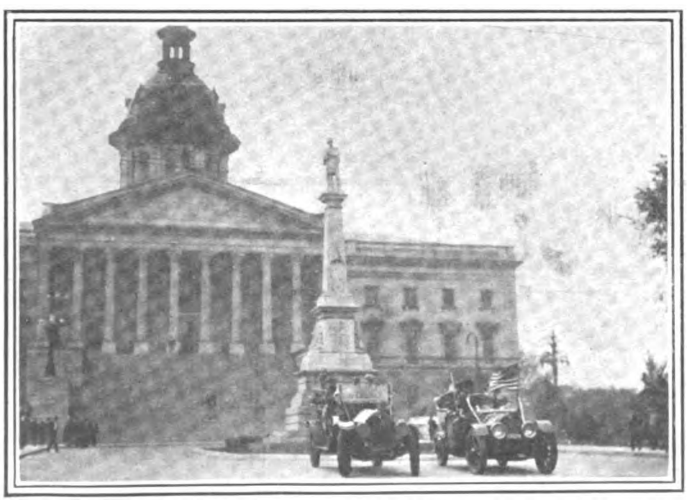
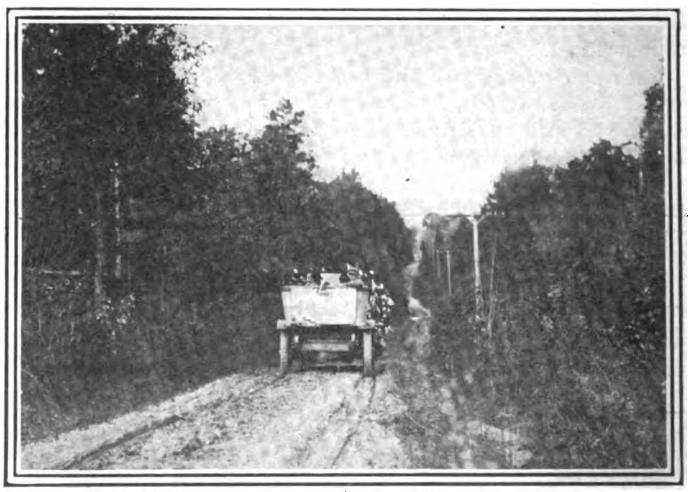
Capital Highway South's Trunk Line

THE most flattering thing you can say to Atlantans is that they live in the New York of the South and that Peachtree street is their Broadway. Indeed, it is harder to drive a car through Peachtree street than through Broadway because all the north and south travel is crowded onto this comparatively level thoroughfare and the traffic regulations are *nil*, each cart or carriage being a law unto itself. The street lights of lower Peachtree street are more picturesque and illuminating than those of Broadway, and, while it lacks the skyscrapers and electric signs of the "Great White Way," there is still the air of a bustling metropolis which the Northern visitor is scarcely prepared to see. There are about 12,000 automobiles registered in Georgia of which more than 3,000 are in Atlanta, being one to every tenth family. This, with other considerations, makes Atlanta the logical touring center of the South and consequently the most desirable point to be linked with New York by trunk-lines of motoring highway.

So much attention has been directed to the so-called National Highway that the unthinking may have lost sight of that other movement for the improvement of the Capital Highway, which has recently been covered *in toto* by the scouts of the Touring Club of America. This movement has been fostered by the Capital Highway Association, of which Leonard Tufts is the president, and so much work has been done within the past three years that to-day more than two-thirds of the road between New York and Atlanta is in excellent touring condition and the balance is rapidly being completed. All of this improvement below Richmond consists of building sand-clay roads, which, when properly constructed, are equal to macadam. The peculiar physical location of this route gives particular encouragement to the use of these materials for it approximately skirts the edge of the clay belt and in some cases one can literally dig sand from one side of the road and clay from the other. Then, too, it reaches the capital of every Southern State which it traverses, including the national capital at Washington, to say nothing of the numerous Winter resorts, such as Pinehurst, Camden and Aiken.



Lined up in front of the battle monument just before leaving Columbia



Lands in Harnet County, N. C., are barren and roads unimproved

The only point on the Capital Highway of which the tourist should be warned is Culpeper, Va., where a carpet-bagging J. P. holds court, ably abetted by a horse doctor, both of whom in their more prosperous days hailed from a well-known Northern State. The first ten days' run of the recent scouting tour of the T. C. A. was made from Atlanta to Augusta, following closely the Georgia Central Railway. The distance is 172 miles and was covered in ten hours' elapsed time through a driving rain. The only bad stretch is 20 miles between Madison and Greensboro, which is mostly slippery red clay. Beyond Greensboro the road is sandy, the last 20 miles being built of the famous cement gravel which is found in abundance in this section.

Crossing the Savannah River at Augusta the scouts entered South Carolina and found on the way to Aiken much improved sand-clay road. Aiken is also a famous Winter resort, whose most famous restaurant is conducted by the former chef of William S. Whitney. The road between Aiken and Columbia is mostly of sand-clay, but it has not received the attention it deserves and consequently is full of ridges where the ground is too high and full of holes where the surface is too flat. The first 15-mile stretch out of Columbia was considered at one time the best example of sand-clay road in America, but this has been allowed to deteriorate, though one can still make excellent time over it. About half of the remainder of this road to Camden has been improved and work is still in progress. A new hotel at Cheraw furnishes first-class accommodations, supplemented by a complete garage and machine shop. From Cheraw to the State line one of the worst stretches of the trip is encountered.

Innumerable fords were encountered by the pathfinders in the Carolinas

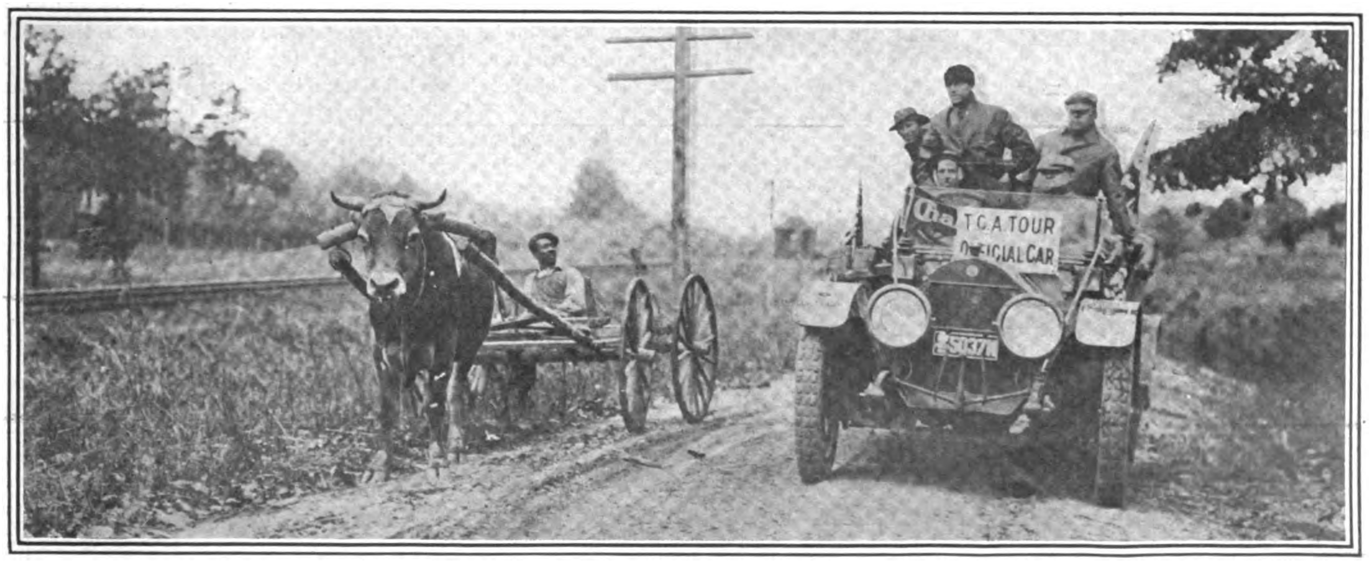
Entering North Carolina the roads improve and continue excellent through Rockingham, a cotton manufacturing town with hotel and garage accommodations. A short stretch of narrow sandy road is encountered after one turns off the main road into the pine woods, but the last 15 miles, entering Pinehurst, is the best trip thus far, due particularly to the fact that is has been dragged.

The scouts arriving in Raleigh, N. C., on the fourth day

The direct road from Pinehurst to Raleigh is 81.7 miles, but, owing to the fact that little interest is manifested along this route the scouts were advised to go via Fayetteville. After passing through Harnet County one encounters some very poor narrow, sandy roads, but upon entering Wake County the road gradually improves and is fine as one nears Raleigh, the capital of the State, and famed as the birthplace of Andrew Johnson. After crossing the Neuse River a splendid new road is followed which though winding, is of excellent construction, and the 45 miles to Henderson is handily covered in 2 hours. From Henderson to Roanoke Rapids, a cotton milling town, the road is fair-to-good, but after crossing the Roanoke River, where a toll of 50 cents is exacted, a stretch of very heavy sand is encountered for about 10 miles. This is amply compensated, however, by the magnificent stretch of sand clay road from Barley to Emporia, a distance of 15 miles.

After leaving Emporia the old Coast Line right-of-way is followed for a short distance. Then comes a stretch of well-graded road which needs a proper dressing of sand-clay. Fifteen miles out begins the most wretched part of the whole Capital Highway, which extends 7 miles to Stony Creek. From Stony Creek the Coast Line right-of-way is followed into Petersburg.

The scouting tour was terminated at the Hotel Jefferson, Richmond, the car having covered 715 miles in less than 5 days, but would be more comfortably taken as a tour in 6 days. With the improvements now in progress and with careful driving the trip can be made in comfort in that time.



The railroad, the ox-cart and the automobile—three types of transportation exemplified

Pope Stars in Phoenix Races

PHOENIX, ARIZ., Nov. 9—Two serious but not fatal accidents marred an afternoon of sensational racing at the Arizona fair grounds to-day. Harris Hanshue, of Los Angeles, and Fred Fuller, of En Centro, both driving Mercers, crashed through the fence but miraculously escaped with their lives.

Traveling faster than a mile a minute, Hanshue punctured the inner railing on the fourth turn of the mile track. When picked up by the attendants in a Red Cross truck, which was on the grounds, Hanshue was unconscious. An examination proved that he had received only a severe wound in the head, a strained hip and various bruises. There were no internal injuries. Fuller was only shocked. His car was a total wreck, but Hanshue's machine left the grounds under its own power.

Hanshue's accident occurred during the 10-mile handicap race for all the cars that participated in the Los Angeles-Phoenix road race. For several miles the Franklin and National were struggling for first place, then the Mercer moved up until it was just behind the National, which Ed Swanson, mechanician to Harvey Herrick, who won the Phoenix race, was driving. Hanshue took several long chances in attempts to swing in and grab the pole. While he was taking one of these chances the steering knuckle broke and the Mercer rammed a hole in the fence. Before he was thrown out Hanshue had time to jam on the emergency brake. He went in one direction and the car in another.

This race was won by the National, with the Franklin, driven by Guy Irwin, second. The other starters were: W. D. Tremaine, in the Pope-Hartford, Bill LaCasse, in the E-M-F, George Soules in the Flanders, W. F. Brong, in the Case, and Charles Bigelow, in the Cadillac. The National was the basis of handicapping. The Flanders was given 50 seconds start; E-M-F and Case, 30; Cadillac, 20; Pope and Franklin, 15; Mercer, 10.

Fuller's accident occurred during the 25-mile, free-for-all for cars with a piston displacement of more than 231 inches. Bert Dingley started in the racing Pope, Hanshue in his Mercer, Swanson in the Phoenix road race National, Fuller in the Phoenix racer Mercer, Frank Seifert in the National that won the Santa Monica race and Louis Nikrent in a Buick.

Fuller never figured as a possible winner, but drove a daring race. He took one chance too many and at the second turn crashed through the outer fence. He went up in the air several feet but came down in the disintegrating car.

The Pope got the best start but the National was close, with Hanshue's Mercer and the other cars strung out behind. Dingley ran the first 5 miles in 4:46.05; 10 miles, 9:30.36; 15, 14:19.17; 25, 23:52.96. The National was second with the Mercer a close third.

By far the most sensational race of the day was the 10-mile free-for-all. Mile after mile Dingley, in the Pope, and Seifert, in the National, struggled for first place. No prettier race ever was seen on any track. Dingley won easily, once he secured the pole. He did so only after many sensational trials and hair-raising escapes from collisions. Seifert got away first and hung to the pole. It was during the eighth mile that Dingley took the lead. This mile was covered in 52 4-5 seconds, and is said to have been the fastest mile ever made in competition.

Five cars started to beat the Phoenix track record of 56 seconds, held by the Apperson. Both the Pope and National succeeded. The Pope's time was 52 3-4 seconds and that of the National 52 4-5. Louis Nikrent covered the mile in 57.35 with his California Buick; Tom Carrigan, in the Midland, made it in 1:05.56 and William Ferguson, who drove the Arizona Buick, in 1:05.56.

With one exception the time of the Pope is the fastest ever made on the Pacific Coast over a mile circular track. The record is 51 4-5 seconds and was made by Barney Oldfield, with a 200-horsepower Blitzen Benz.

Four machines started in the 15-mile event for cars participating in the Phoenix race, having a piston displacement of 301 inches or over. There was a pretty struggle for first place between the National and Nikrent's Buick, but the National won. Its time for 5 miles was 4:57.55; 10 miles, 9:43.22; 15, 14:37.67. The Buick was second, with the Franklin third and the Midland fourth.

Hanshue was the hero of the 10-mile race for cars in the Phoenix race, having a displacement under 301 inches. At the start the Cadillac, driven by W. W. Bramlette, and the E-M-F, took the lead. The Mercer, Case and Cole, with John Jenkins at the wheel, were strung out behind. Soon it became evident that the Mercer was more of a factor than had at first appeared. Hanshue kept on the outer edge of the track and crept up, passing first the E-M-F and then the Cadillac. That happened during the fifth mile. Thereafter no interest attached to the race except for Hanshue's fast driving. Finally the E-M-F slowed up and was passed by the Case. They finished with the Mercer first, Cadillac second, Case third, E-M-F fourth and Cole fifth. The Cole was distanced, owing to a cracked cylinder. Hanshue's time for the 10 miles was 10:34.05.

There was a special event for the cars in the Phoenix race that arrived first, second, third and fourth, but W. D. Tremaine's Pope, which came in fourth, did not start. The National took the lead and easily held it to the end, winning in 10:15.56. There was a fight between the Cadillac and the Franklin for second place, but the Cadillac won out, taking the lead in time to beat its rival.

An attempt was made by George Soules, in a Flanders, to lower the world's 5-mile circular track record for 20-horsepower cars. The record is 5:42 but the best that Soules could do was 5:57.51.

Entries for the French 1912 Grand Prix

For the combined international two-day *Grand Prix* and *Coupé d'Auto* race to be run in France in the Spring, over a distance of about 2,000 kilometers and under the management of the Automobile Club de France, the number of entries by any one firm of manufacturers is limited to 4. Unless at least 30 entries shall have been duly received on ore before December 30, 1911, the event will be called off and the entry fees refunded. American as well as other nominations must be in the hands of the Sport Committee of the Automobile Club de France before the date mentioned accompanied by the regular fees, which are $300 for one car, $500 for 2, $750 for 3 and 900 for 4. Thereafter, if the requisite number of entries for securing the event has been received and accepted, additional entries will be accepted at doubled fees up to March 31, 1912.

Cars of any preferred design, size and power may take part in the Grand Prix section of the event, excepting that the track width, from hub to hub, center to center presumably, must not exceed 1.75 meters.

If more cars are entered than can safely be run, in the opinion of the management, the Sport Committee reserves for itself the privilege of reducing the number by drawing lots or any suitable means.

Hudson and Cadillac Win Harrisburg

HARRISBURG, PA., Nov. 14—A Hudson, entered by I. W. Dill and driven by Roy Hamilton, won first prize in the dealers' class, and a Cadillac car, owned by W. P. Starkey, and driven by himself, won the first prize in the private owners' class of the Harrisburg economy run given yesterday by the Motor Club of Harrisburg, from Harrisburg to York. The cars before leaving on the 104-mile trip yesterday morning were sealed and upon their return last evening were opened by the technical committee and the amount of the gasoline consumed on the run was then recorded. The Hudson car consumed 5 gallons and 1-8 pint and the Cadillac car 6 gallons and 1 quart on the entire trip.

The cars left Market Square at Harrisburg and the pacemaker, a Pullman, in charge of E. G. Brandt and Referee Douglas, was the first machine away at 9:38. The others cars got away at 1 minute intervals and took up the course to York at a 16-mile an hour speed. The route of the run lay through Dauphin, Cumberland, York, Adams and Lancaster counties. After crossing the Susquehanna river and passing Camp Hill the machines went to Dillsburg, East Berlin, Abbottstown, Hanover, Menges Mills to York, where a stop of 90 minutes was made for lunch. At 2:18 the machines began to depart via Columbia, Florin, Marietta, Middletown and Steelton. The roads were in fairly good condition, the only hindrance being the cold. The cars checked in at Market Square at 4:45 o'clock. Seventeen cars carrying 70 persons were entered in the run and all finished the run with the exception of 2 cars that were withdrawn. Three cars met with accidents, which included the two Kline Kars entered by the Kline Motor Corporation. Up until the accidents, the cars had made an excellent showing.

The following shows the total fuel consumption:

No.	Car.	Entrant.	Gal.	Qts.	Pts.
5	Hudson	I. W. Dill	5	0	⅛
14	Cadillac	C. C. Crispen	5	1	1¾
4	Hudson	Murray Dick	5	2	1
6	Inter-State	I. W. Dill	5	2	1⅔
13	Cadillac	H. D. Delmott	5	3	½
17	Cadillac	C. C. Crispen	6	0	1¼
15	Cadillac	W. P. Starkey	6	1	0
3	Chalmers	R. L. Morton	6	1	½
9	Flanders	E. L. Craft	6	3	1½
16	Cadillac	C. E. Covert	7	2	½
19	Everitt	G. C. Furl	7	2	1
7	Chalmers	Jno. Gallagher	7	2	1½
8	E-M-F.	E. L. Craft	7	3	1⅛
2	Hudson	J. H. Benfer	8	3	0
11	KlineKar	J. A. Kline	8	3	1½
12	KlineKar	J. A. Kline	Withdrawn		
18	Reo	G. G. McFarland	Withdrawn		

The awards were based upon the following cost per mile per passenger:

Class A, Touring Cars, $1,000 and Under

9—Flanders	.00212		

Class B, Touring Cars, $1,000 to $1,500

19—Everitt	.00233	8—E-M-F.	00242

Class C, Touring Cars, Above $1,501

5—Hudson	.00154	3—Chalmers	.00195
14—Cadillac	.00167	13—Cadillac (4 pas.)	.00222
6—Inter-State	.00175	7—Chalmers	.00235
17—Cadillac	.00188	2—Hudson	.00268
15—Cadillac	.00191		

Class CC, Runabouts, Above $1,501

4—Hudson	.00430	11—KlineKar	.00683
16—Cadillac	.00531		

National Wins at San Antonio

SAN ANTONIO, TEX., Nov. 13—A three-day track meet run by the San Antonio Club, was completed this afternoon, the feature of which was a 4 1-2-hour race split into three sections of 1 1-2 hours a day this was won by a National, driven by Sutherland, the car covering 225 miles in the 4 1-2 hours. Second was a Jackson, driven by Meleun, with 216 miles; third was an E-M-F, driven by Reeves, 213 miles; fourth was a Staver-Chicago, driven by Knudson, 203; and fifth was a Flanders, driven by Potter, 195 miles. Ten originally were scheduled to start, but the Cutting went out early because of a loose radiator, while the Flanders caught fire at the pits and was withdrawn.

Originally the meet was scheduled to start last Thursday, but the weather conditions were such that the 3-4-mile track was deemed unsafe so the actual racing was postponed to Saturday, continued yesterday and finished to-day. Before the start of the long grind each day there were short-distance races in which the Cino did especially well. The summaries of the three days of racing follow:

FIRST DAY

Class C, Division 3C, Non-Stock, 12 Miles

Pos.	Car.	Driver.	Time.
1	Cino	Raimey	13:49
2	Staver-Chicago	Monckmeier	
3	E-M-F.	Reeves	

Special Match Race, Five Laps

1	Cutting	Clark	4:22⅖
2	Jackson	Fred Meleun	

Class D, Non-stock, Free-For-All, 21 Miles

1	Cino	Raimey	24:29
2	Staver-Chicago	Monckmeier	

4½-hour Race, First Section (62 Min.)

National, 72 laps; Ohio, 72 laps; Jackson, 71 laps; Staver-Chicago, 69 laps; Cino, 68 laps; Staver-Chicago, 66 laps; E-M-F, 63 laps; Pope-Hartford, 56 laps.

SECOND DAY

Class C, Division 3C, 9 Miles

1	Cino	Raimey	9:53⅘
2	Staver-Chicago	Knudson	
3	Staver-Chicago	Monckmeier	

Free-for-All, 15 Miles

1	National	Sutherland	16:41⅖
2	Staver-Chicago	Monckmeier	
3	Jackson	Meleun	

4½-hour Race, Second Section (118 Min.)

Total distance—National, 202 laps; Jackson, 195 laps; E-M-F, 187 laps; Staver-Chicago, 177 laps; Flanders, 171 laps. Leader's mileage, 152½.

THIRD DAY

First Event, 16 Laps, 12 Miles, Class C, Division 4-C

Pos.	Car.	Driver.	Time.
1	Cutting	Clark	12:56.20
2	National	Sutherland	
3	Jackson	Meleun	

Second Event, 24 Laps, 18 Miles, Class E

1	Cino	Raimey	21:05
2	E-M-F.	Reeves	
3	Staver-Chicago	Knudson	

4½-Hour Race, Third Section (90 Min.)

1	National	Sutherland	225 miles
2	Jackson	Meleun	216 miles
3	E-M-F.	Reeves	213 miles

Flanders Cars Break Class Records

INDIANAPOLIS, IND., Nov. 14—New records were established at the Indianapolis Motor Speedway yesterday. Frank Witt drove a Flanders Class B stock car in Division 1B, 160 cubic inches and under 1 mile in 56.80; 5 miles in 4:22.98; 10 miles in 9:27.49; 15 miles in 14:13.26; 20 miles in 19:00.87. Robert Evans drove a Flanders Class C, 160 inches and under, 1 mile in 56.80; 5 miles in 4:26.10; 10 miles in 8:53.95; 15 miles in 13:24; 20 miles in 17:54.80.

F. E. Edwards, A. A. A. technical committee, examined the cars, and the timing was done by the Warner electrical device. It was intended to go after 25 and 50-mile records, but the cold was too great for the drivers.

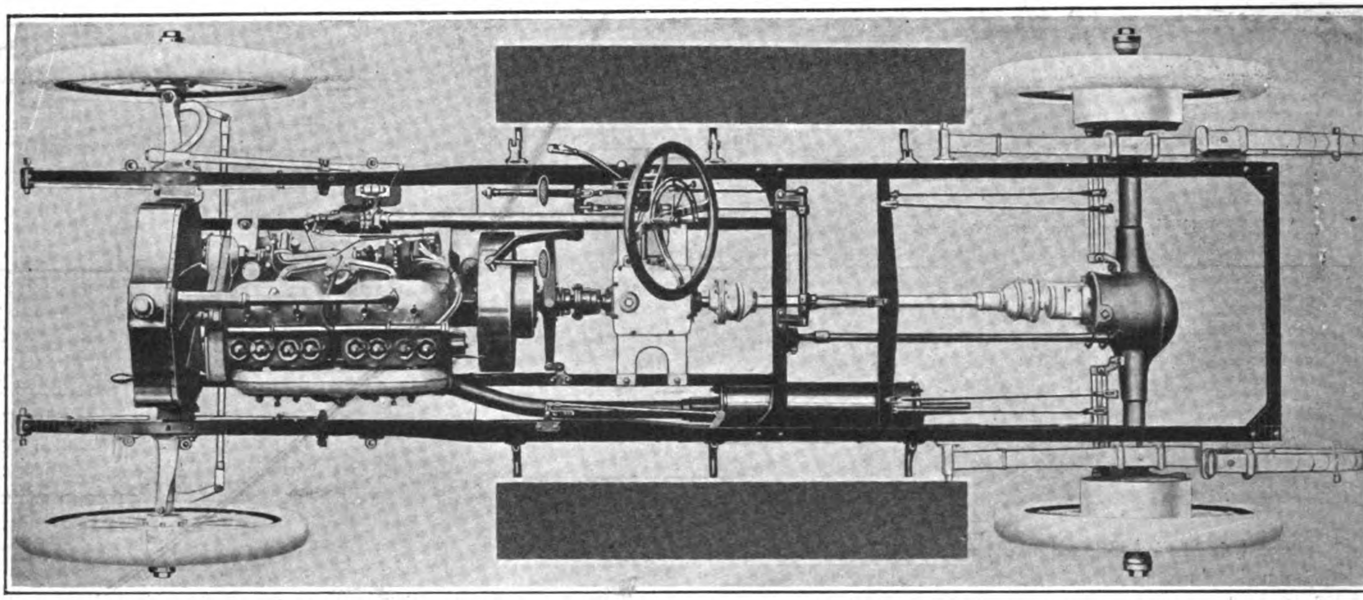


Fig. 1—The standard chassis used in connection with all models of the Selden line

Selden Refinements for 1912

A SINGLE chassis features the Selden line of cars for the season of 1912. The various styles of body are fitted upon this chassis and the only change necessary in the constructive details when fitted with bodies of different types is in the steering columns and control levers.

The motor is rated at 40 horsepower and has a bore of 4 3-4 inches and stroke of 5 inches. There are four cylinders, which are cast in pairs with the valves all on the left side of the motor. All the valves are made interchangeable, having a diameter of 2 1-4 inches and a lift of 5-16 inch. A feature of the cylinder casting is that it is arranged with a web which forms the basis of a cover which serves to completely house the valve mechanism. The covers are easily removable by turning the hand screws, which may be seen at C, Fig. 3. The manifolds are held to the cylinders by means of the dogs and studs which are shown at D. A detail of interest is the manner in which the indicator P is attached to the engine frame so that the marks on the flywheel corresponding to the phases of the cycle may be easily read.

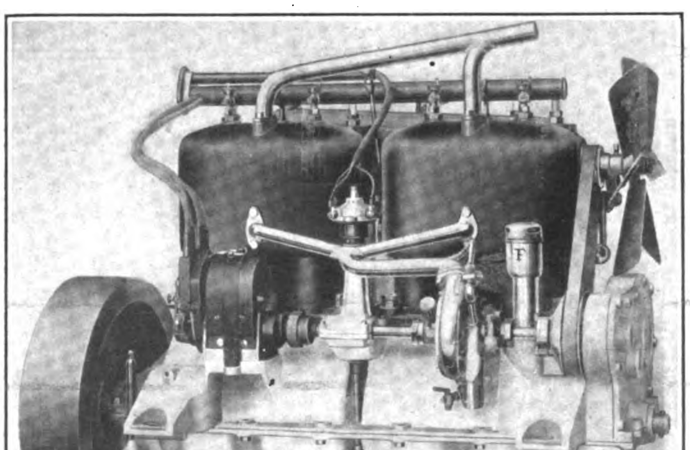

Fig. 2—Right side of the Selden 40-horsepower motor, showing the magneto and pumps

The motor is water-cooled, the cylinders being cast integrally with their water jackets, which have removable covers so that they may be readily cleaned when necessary. The water is circulated by means of a centrifugal pump located on the right side of the motor and driven by a horizontal shaft which is actuated by a set of gears contained in a housing at the front end of the motor. The water pump is of large capacity so that a sufficient supply of water will be assured at all speeds. There are baffle plates located within the water jackets so that the water will be directed to the most needed points and a reliable circulation maintained. The water is led to and from the radiator by means of seamless brass tubing, the end connections being made by using specially treated rubber. The square-tube radiator is kept cool by means of a six-bladed fan which is driven by a belt from the same shaft as that which drives the water circulating pump. The fan is mounted on ball bearings and is fitted with an automatic spring tension for the belt. There is a removable coupling in the shaft so arranged that it is very easy to take out and replace the belt without disassembling any other parts of the motor. The crankshaft is a drop forging of nickel steel specially heat-treated. It is carried upon three large plain bearings which are lined with die cast soft metal.

The camshaft is of the built-up type; that is, the cams are machined and hardened separately and then pinned to the shaft in their proper positions. In case of an injury to one of the cams it may readily be removed and replaced without tearing down a large part of the assembly.

The valve push rods are of the mushroom type, acting directly between the cams and the valves. To render desired adjustments easily possible, screws are fitted by means of which any wear may be taken up. The push rods act in guides, which tend to reduce chattering and rapid wear in the valves and the other parts of the valve action. The push rods and their guides are so constructed that they may be readily removed without interfering with any other part of the valve or engine mechanism.

The carbureter is carried on the left side of the motor; it is of the Stromberg double-jet type and is fitted with a hot-water jacket. The gasoline feed is by gravity and is governed by float and needle valve in the carbureter. The gasoline tank is located beneath the driver's seat and has a capacity of 17 gallons.

There has been no change made in the ignition system of the new car, the Bosch magneto, type DR-4, being used in connection with one set of spark plugs, while an independent battery system is connected to another set of plugs. The spark coil is of the master vibrator type in which there is but one vibrator, so that a uniform spark will be supplied to all the cylinders. As there is a cut-out button on each of the coils it is possible for the operator to at once determine the location of a misfire. All the coil units are easily removable from the casing, which is hinged for this special purpose. Current for the coil is supplied by six dry battery cells located on the running board.

The motor is lubricated by means of a splash system in which the oil is maintained at constant level. The oil is carried in the lower part of the base casting, which is so arranged as to carry both the reservoir for the oil and the troughs by means of which the splash system of lubrication is operated. The lower part of the casting in which the oil is carried has a capacity of 6 quarts and is separated from the upper part of this casting by means of a horizontal tray which carries the splash troughs. There is one of these troughs below each crank throw. The oil is lifted from the reservoir by means of a gear pump which takes the lubricant from the base and puts it into the troughs. The pump is driven by means of a vertical shaft which is actuated by the horizontal shaft driven by the gears at the forward end of the motor. The timer is located at the upper extremity of this shaft, while the oil pump is at the lower.

Besides pumping the oil from the reservoir to the troughs the oil pump also sends it through a lead to the timing gear case, thus insuring ample lubrication at all times. After having lubricated the gears, the oil will drain back to the crankcase. The oil in the troughs is picked up by the ends of the connecting rods and thrown up into the cylinders, which are thus lubricated. The beating action of the connecting rods into the pools of oil formed in each of the troughs churns the oil into a fine spray or mist which pervades the entire crankcase, thus lubricating all the moving parts therein contained. The pump is continually supplying the oil to the troughs at a much more rapid rate than it is being consumed; hence there will be a continuous flow through the overflow ports back into the reservoir. To prevent any accumulated foreign matter from passing through the motor after the oil has once carried it down to the reservoir, there is a screen provided through which all the oil must pass. This screen is inserted in the path of the oil to the pump.

The reservoir is filled through the filler hole F, Fig. 2, which is located on the right side of the motor near the front. It is covered with a screw cap and is fitted with a screen through which the oil must pass. The amount of oil within the crankcase may at all times be determined by means of the ball gauge which is located at the front end of the motor on the right side. The

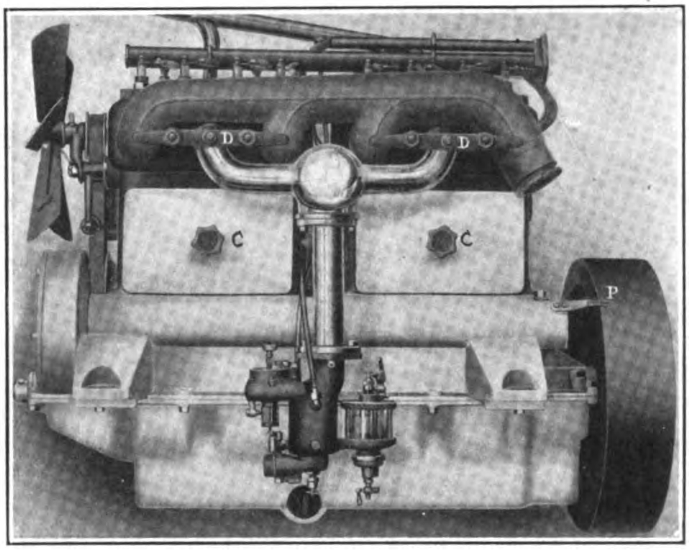

Fig. 3—Left side of the Selden motor, showing the location of the carbureter and manifolds

ball riser is of steel and its position may be ascertained by the hand in case the car is in darkness at the time the oil level is to be determined. If there is so much oil within the crankcase that it causes the motor to smoke, the drain cock C in the bottom of the crankcase may be opened and the excess oil allowed to run out.

The clutch is of the multiple disc type, and is enclosed in a housing which is bolted to the flywheel. There are thirteen discs, the driving members being faced with an asbestos composition which is riveted in place while the driven discs are left unfaced. The inner or driven housing holds a pair of heavy spiral springs which supply the necessary pressure. The tension on the springs may be regulated by means of a pressure plate and three studs which extend through the plate. By means of these studs the required adjustments may be made without the removal of any housing or other parts. An automatic spring lock secures the studs and prevents them from turning.

A universal joint of the gear type, consisting of a pinion on the transmission shaft inserted in an annular gear of equal size, connects the clutch with the transmission and allows sufficient lateral play to permit of the clutch being readily thrown out of engagement without any rattle or lost motion. The transmission bearings are so arranged that any thrust due to throwing out the clutch is taken up by them, relieving the motor entirely of this duty. To prevent the clutch from spinning when changing

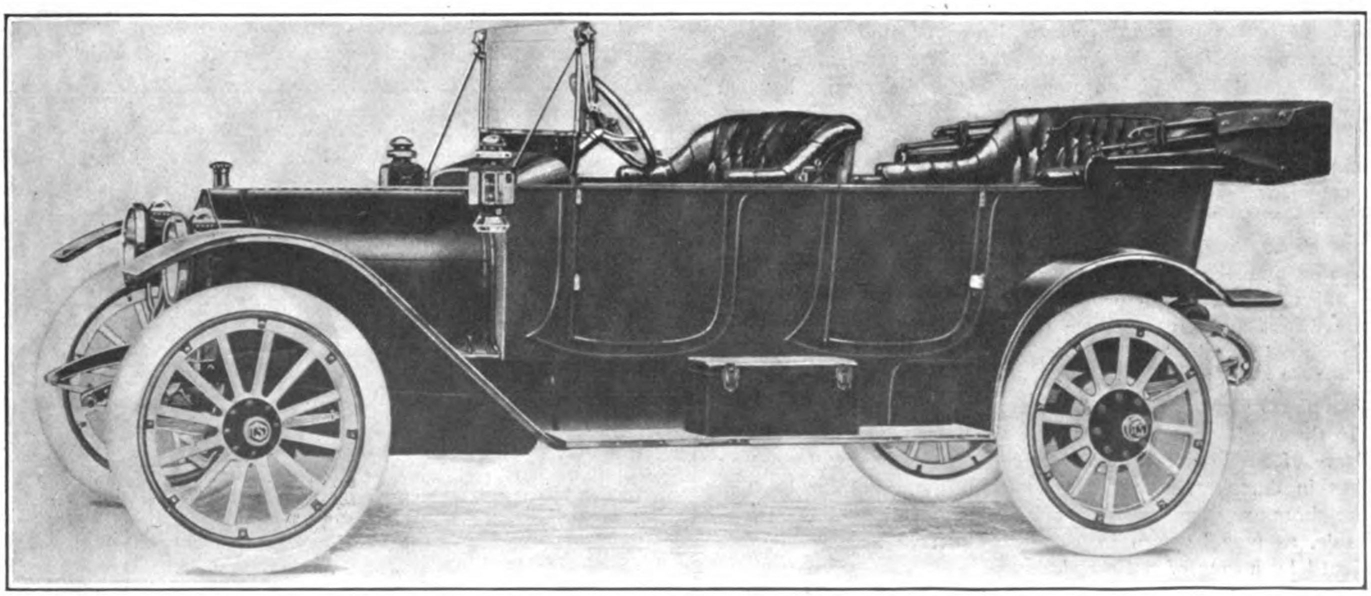

Fig. 4—The Selden model 47 is a fore-door, five-passenger touring car of roomy dimensions

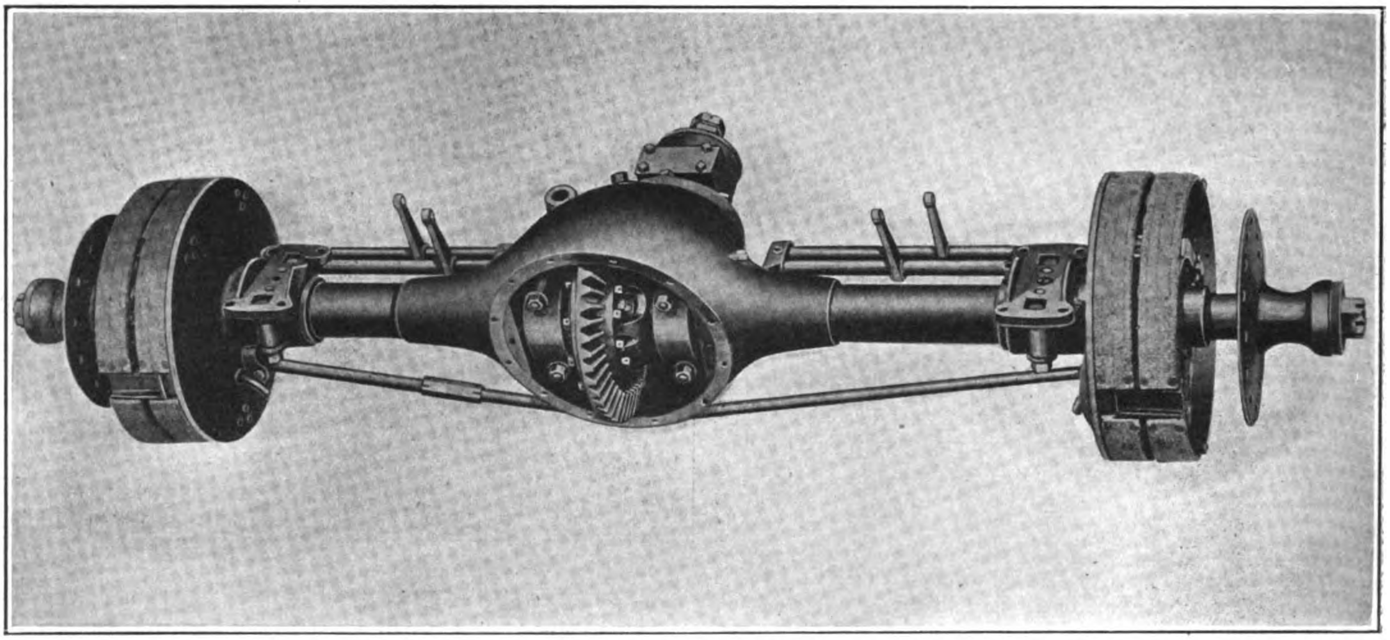

Fig. 5—Illustrating the rear axle of the Selden cars with the differential cover removed

gears, a brake is fitted, thus aiding in this important operation.

Connected to the clutch pedal by a system of levers is the ball thrust. The levers and thrust are so arranged that a light pressure on the pedal will be sufficient to manipulate it. The emergency brake is interlocked with the clutch so that when the brake is applied the clutch will be disengaged, although if it is so desired, this interlocking device may be readily removed. The clutch may be easily disassembled by the removal of a few bolts so that repairs may be simply and readily made when necessary or inspection facilitated.

The gearset is of the sliding selective type with three speeds forward and one reverse, high speed being on direct drive. The shafts run on Timken roller bearings which are adjustable for wear from the exterior of the case, and hence when any adjustments are necessary it will not be required to dismount any of the mechanism. The gearset housing is an aluminum casting which is carried by the subframe by means of four supporting arms which rest upon the top of the frame. Inspection is made readily possible by means of a cover which may be removed without disturbing any other parts.

The power is transmitted from the gearset to the drive shaft through a universal joint of the Spicer type. The drive shaft is also fitted with a Spicer universal joint at the rear end through which the power is transmitted to the differential.

The rear axle is of the floating type. The drive pinion runs on New Departure ball bearings while the differential housing is mounted upon Hyatt bearings with ball thrust. The differential is provided with a cover which is very easily removable so that the entire mechanism may be exposed for purposes of inspection or repair. The axle shafts are provided with flanges through which the hub bolts pass, the chances for lost motion occurring at this point thus being reduced to a minimum, and at the same time the hub caps are relieved of the duty of holding the axles in place. To prevent the oil from leaking into the brake drums and causing them to slip at some time when they are required to take hold quickly, sleeves are fitted on the hubs which lead any oil that may work out along the axle shaft, into an annular recess in the brake flange, whence it is drained out on to the road. The brakes are of the internal expanding type and are of ample size, the bands being 1 3-4 inches wide and 14 inches in diameter, acting directly upon the rear wheel. The brake shoes are fitted with non-burning material and are set side by side, as may be seen in Fig. 5. The rear axle housing is stiffened by means of a tie rod.

The torsional strains in the rear axle are taken up by a triangular torsion arm of heavy gauge tube steel with drop-forged ends. The stress is transmitted to the central cross member of the frame, which is fitted with a bracket supporting the housing that encloses the front end of the torsion arm and the heavy cushion springs. This housing is made tight in order to exclude all mud and water and may be packed in grease to prevent rattling or other noises at this point. The torsion arms are attached to the axle by means of two short vertical pins.

The front axle is a one-piece drop forging of I-beam section while the frame of the chassis is of channel steel 4 3-4 inches deep and 3-16 inch thick, with three cross members and a subframe which supports the motor and gearset. The frame is raised over the rear axle and so shaped as to allow the use of 3-4 elliptic springs. The rear springs are 51 x 2 1-4 inches. The frame is brought in at the front end in order to provide for an easy turning radius. Semi-elliptic springs are used in front. They are 38 x 2 inches.

The wheels on all the bodies are similar, being of wood 36 x 4 inches all around and are fitted with Firestone Q. D. rims. The bearings upon which the wheels are carried are of the ball type, the rear wheels being provided with New Departure bearings containing two sets of balls, while the front wheels are fitted with adjustable bearings of the cup and cone type. The wheelbase for all models is 125 inches, while the tread is the standard 56 inches. The road clearance is 10 inches.

The steering gear is of the worm-and-gear type, which may

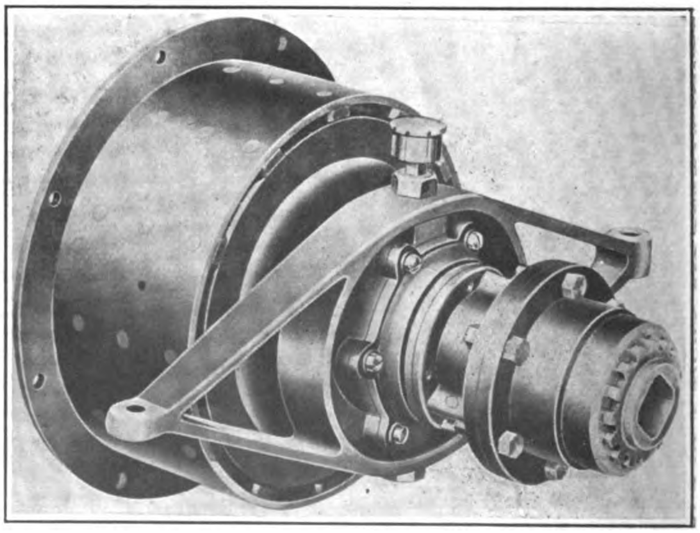

Fig. 6—Showing the dry disc type of clutch employed with all models

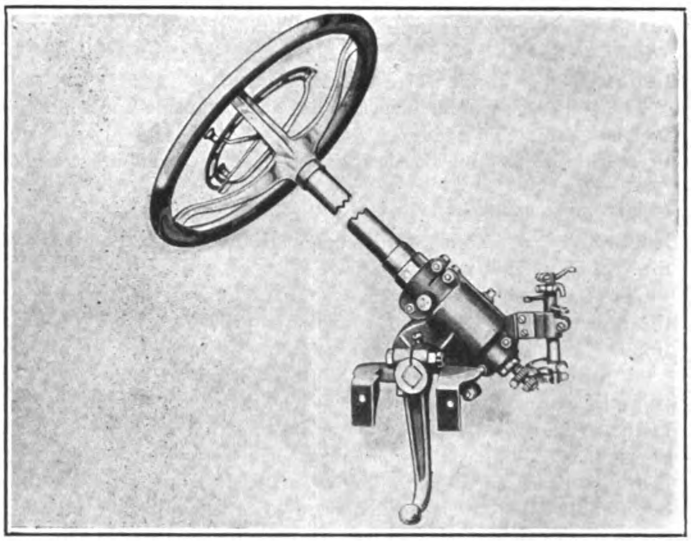

Fig. 7—Condensed view of the steering gear and housing

be so adjusted that four different bearing surfaces are brought into contact with the worm. This method of arrangement will tend to increase the life of the steering parts, as an adjustment may be made from time to time to insure a different part taking up the wear. The steering gear housing is bolted to both the main frame and the subframe in order to secure a stiff and rigid connection. The steering column housing is carried down to the gear casing and connected thereto.

The steering wheel is 18 inches in diameter. The frame of the wheels is of cast aluminum and this is built into a wooden rim of large oval section so that easy grip is secured upon the wheel. The spark and throttle control levers are placed in the center of the wheel on their respective quadrants and held thereto by means of spring catches.

The muffler on the new model car is of the same size as that used in previous years on the Selden cars, but in order to secure a freer exhaust the cut-out valve has been enlarged. A change has also been made in the manner in which the exhaust pipe is supported. The fastening has been so strengthened as to increase the security of the connection, thereby holding the pipe firmly against the vibrations of the car. The mechanism which controls the action of the cut-out has also been completely redesigned.

The foot accelerator, which is fitted to all models, is of the push-button type; it is within easy and comfortable reach of the foot so that the driver may readily operate the car entirely by the manipulations of his foot upon the accelerator pedal.

The head lamp bracket sockets are riveted upon the frame of the car; they are heavy drop forgings and are connected by a tie bar to maintain rigidity. The side lamp brackets are connected to the dash board and carry the front ends of the windshield stay rods.

Another feature which has been changed in the new cars is the length of the running boards, which has been increased to conform to the dimensions of the larger cars. They are now carried upon three step hangers instead of two, so that a stronger connection is maintained. The running board carries the gas tank for the lighting supply and the opposite running board carries the battery box.

A full supply of lamps goes with each model. The head lamps are operated by gas and are suplied by the tank upon the running board; the side and tail lights are a combination of electric and oil. The current for the lights is supplied by an 80 ampere-hour storage battery which is contained in the battery box upon the running board.

The standard equipment furnished with all the cars also includes a top, complete with all curtains and envelope, windshield, battery box, tool box, horn, robe rail, foot rail, muffler cutout, tire irons and a complete set of tools.

The types of bodies furnished with the new chassis are of five different varieties. The model 47 is a five-passenger touring car of the fore-door type. Model 47-S is larger, being classed as a seven-passenger touring car, likwise of the fore-door type. Model 47-T, known as a four-passenger torpedo, is built along racy lines and is adapted for four people, being of long narrow construction. The 47-R model is a two-passenger roadster with a rumble seat, making the carrying capacity three; this car is also constructed with the idea of presenting a racy appearance and is designed to meet the requirements of those who do not need a larger car. The limousine, which is known as model 47-L, is of large dimensions, being constructed for a seven-passenger capacity; the aluminum body is of special design and will accommodate five passengers in the rear compartment while the front seat will accommodate two. The limousine body, as well as the chassis and running gear, will be painted in standard blue or Brewster green and will be trimmed in broadcloth or cord to match.

The equipment of the limousine will include a divided glass front, removable cab sides, side curtains, two extra swing seats, foot and robe rails, dome lights, toilet case and umbrella holder.

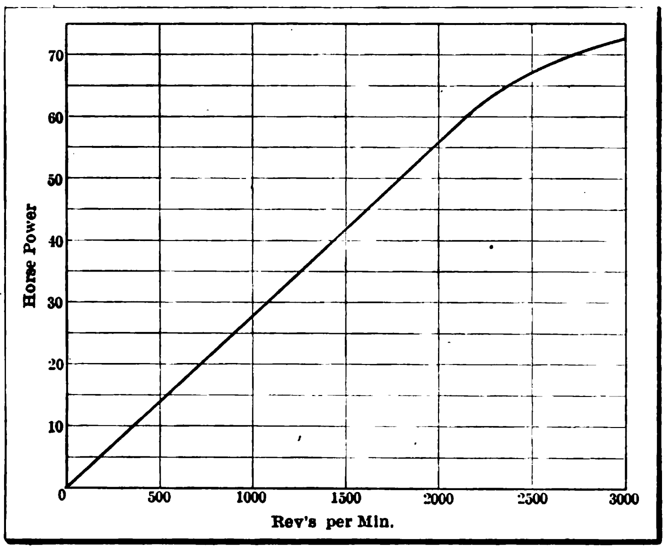

Fig. 1.—Power curve of a 3.3-inch motor, showing a remarkably steady rise

Engine Efficiency

AS an indication of the difference between the average stock model and the car that is specially prepared for racing purposes some figures recently published in England by the Austin Motor Company show what can be attained in the way of efficiency by special fittings to the motor. The piston speed of a motor is dependent in a measure upon the weight of the reciprocating parts, and it has been the aim of designers to make these as light as possible consistent with the stresses and strains they are compelled to undergo. Pressed steel has been adopted of late years for the pistons on some racing motors, but one disadvantage of this method of manufacture lies in the fact that out of a dozen blanks several are often found to be faulty. This enhances the initial cost and would be too dear a proposition for stock cars. However, when the cost is not a matter of importance there is no doubt that the steel piston is lighter than the conventional cast gray iron variety.

The pistons of the motor under consideration were steel and together with their wrist pins and rings weighed 1 pound each. Connecting rods weighed 1 1-2 pounds each and the motor was a four-cylinder monobloc with a bore of 85 millimeters (3.34 inches) and a stroke of 115 millimeters (4.527 inches).

The power curve of the motor shown in Fig. 1, which is reproduced from *The Autocar,* indicates a remarkably steady rise up to 2,300 revolutions per minute, when it falls off only very slightly and continues to 3,000 revolutions, registering 72 horsepower at that speed.

Fig. 2 shows the possible speeds of a car fitted with this motor. The gear ratios are as follows:

First speed	9.7:1	Third speed	3.9:1
Second speed	5.0:1	Fourth speed	3.0:1

The ignition used on the motor under test was one that gave two sparks at the same moment, and two carbureters were employed.

Two Sets of Advice on "Knocking"

When the well-known knocking sound is heard from the automobile, and it cannot be ascribed to loose connecting-rod bearings, several other possible causes may be looked into. The staybolts of the magneto may have become loose, in which case the magneto is likely to rock on its bracket and produce the sound of knocking.

A tooth in the camshaft gearing may have been broken.

The fan belt, if one is employed, may strike against one of the fan blades.

The hood may be loose and knock against its support or against the radiator.

An exhaust pipe joint may be loose, and the exhaust will then regularly produce a sound similar to that of a crankshaft knock.

The valves may be noisy, by the design of the valve cams or too much play in the valve lift mechanism.

The joint of an inlet pipe may be loose, causing too much air to enter the cylinder affected, and this will cause real knocking, even if the connecting rod bearings are tight.—From *La Pratique.*

—

The same subject is treated in another publication at greater length and, as it seems, with some variance in the diagnosis of the trouble. This doctor says:

The knocking may come from the crankshaft bearings, from the camshaft bearings and from the camshaft gears. The location of the cause can in these cases only be decided by a complete dismounting of the motor. It is better to look for other possible causes first. A badly seated valve or too much play in the valve control may be at the bottom of the trouble. Next, the flywheel should be examined; it may be rocking on its keys. A fouled or cracked spark plug or a poorly connected wire may be at fault. An experienced driver, however, will have no trouble in distinguishing the noises from the ignition or the carburetion system from real knocking.

If the knocking comes really from the motor or the flywheel, it continues of course if the motor runs while the clutch is out, and this is the way to try it.

If there is knocking with the change-gear lever on neutral and the clutch in, and the knocking stops when the clutch is disengaged, the cause is necessarily in the clutch, the intermediate shaft or the primary shaft of the transmission. The latter may knock from wear of bearings or when it has become misaligned with the motor shaft through twisting of the vehicle frame. Such misalignment will soon ovalize the bearings, and it is therefore of no use to remedy the knocking by relining these, unless the misalignment of the frame is first corrected. The ever extending use of a universal joint between the clutch and the transmission box now almost eliminates this cause from the possibilities by rendering a misalignment harmless.

The intermediate shaft comprises sometimes a bearing mounted in one of the cross girders of the frame. There, too, if there is misalignment, knocking may follow. And these forms of knocking, as well as those arising from a too stiff or too loose clutch, be it a metallic Hele-Shaw or Mercedes band clutch or a leather-

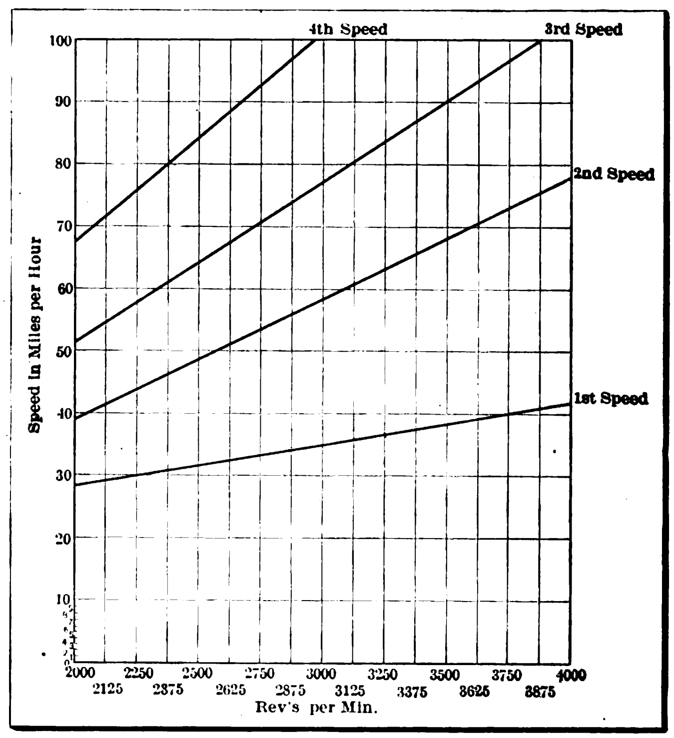

Fig. 2—Diagram showing the speed in miles per hour of a car fitted with a 3.3-inch bore motor

faced cone, resemble closely that from a loose connecting-rod bearing. In the case of the Hele-Shaw clutch, shortage or excess of oil or even only the poor quality of oil is sufficient for producing the same effect. The remedies are obvious.

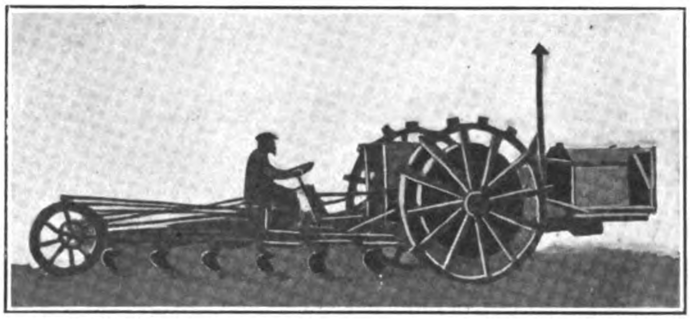
Suppose that one hears the knocking while the vehicle is running, but that it ceases when the vehicle is stopped and the motor turns without load. It may be that the motor is nevertheless the cause. Some motors knock even when everything is in normal order, as soon as the spark timing is no longer in accordance with the motor speed; but, barring this exceptional case, the sound must come from the transmission, from the driving shaft or from the brakes. The sound in these cases is an entirely different and much less frequent one. Its origin may be found by raising the rear end of the vehicle, resting it on a box for example, and running the motor. By engaging the different gear speeds successively and applying the brakes while immobilizing one wheel and then the other, the trouble is soon located. And, if only an adjustment is involved, as in the case of the brakes, it is also soon remedied.—From *La Vie Automobile*.

Motor Gangploughs

WHILE the makers of continental Europe seek inspiration for the development of agricultural motor machinery in the productions of England and the United States so far as machinery of high cost and high power is concerned, which is best adapted for agricultural operations on a large scale, it is found in all countries that the development of machinery which can be used with real economy by farmers controlling only a limited acreage (and that usually of high price), represents a separate problem or rather a series of separate problems. It has been found especially difficult to devise gangploughs which will do the heavy work demanded of them, under all conditions of surface, soil and weather, with the limited power and small weight of the equipment which are indispensable features for keeping the first cost as well as the cost of operation and maintenance down to a practical minimum.

Professor Dr. Strecker of Leipsic reviews the main construction features in the machines which have been offered in the market with a view to the solution of these difficulties and with special reference to machines driven by gasoline motors. The English Ivel-Motor, weighing 1,500 kilograms and equipped with a 20-horsepower motor, has been found too weak for the work of drawing gangploughs, depending for traction as it does on chain-driven rear wheels alone. The French Bajac tractor of 25 horsepower is designed to draw a three-share plough weighing 1,100 kilograms. In light soil 2 1-2 hectares (6.178 acres) can be worked 20 centimeters (7.8 inches) deep in 10 hours with a consumption of 60 liters (13.2 gallons) of benzol. With a two-share plough weighing 1,000 kilograms 1 1-2 hectares of similar soil have been worked 36 centimeters deep using a slightly smaller amount of fuel. The possibility of deep ploughing under less favorable soil conditions is secured by a winch with a cable capacity of 200 meters. If the soil is so heavy that the motor cannot move the tractor and the plough at the same time, the tractor moves ahead alone unwinding he cable which has been attached to the plough, and, when as far as 200 meters ahead, it is halted and anchored by means of suitable brake arrangements, and then the plough is drawn to it by switching the motor power to the winch. This machine has three gear speeds, the high giving 15 kilometers per hour or 4 meters per second. The cable is wound up—drawing the plough—with a speed of 1 meter per second. The cable can of course also be used, in case of necessity, for pulling the tractor alone out of a slough or mire.

The Deutz gangplough weighs 8,000 pounds and operates four shares. Two plough beams each carrying four shares, are suspended from the machine, one in front and one at the rear. Only one set is in operation at one time, the arrangement having for its object to avoid the onerous and difficult turning of the whole equipment at the end of the furrows. By means of a provision



The Stock-motor plough, in use on many large German estates

for placing both pairs of wheels askew, the machine can be moved laterally the width of the work, whereafter the shares which were in front are let down and the machine moves in the opposite direction, the driver's seat being reversible. When the work is too heavy for the wheel adhesion, a cable is strung across the length of the field being attached to special anchoring vehicles at both ends and passed several times around pulley sheaves on the machine. Ordinarily these sheaves revolve idly, but when necessary for drawing the load they are switched into gear with the motor, and the machine then pulls itself and the plow slowly forward by this means, as a chain steamer draws itself up against a swift current by means of the chain laid down in the river. The equipment costs 27,000 marks and has not yet found extensive employment, though in trials which were held under favorable conditions it proved economically satisfactory.

The Stumpf motor plough weighs 12,000 pounds with a motor of 60 horsepower and a four-share plough and costs 38,000 marks. Traction is secured by broad and large driving wheels to the circumference of which are attached four rows of leaf springs, each spring secured at one end and extending almost tangentially and carrying at the free end a shoe or block which bends the spring to conformity with the rim when it strikes the ground—a system which, it seems, would be liable to be clogged up in wet and sticky soil.

The most interesting and strictly German development is shown in the "Stock-motor" plough which is in use on about forty German country estates and seems to be looked upon as very satisfactory. (The *Automobil Welt* states that it is little known only because the company manufacturing it is averse to all publicity with regard to its construction features.) The motor and the plough are built into a single frame. The 4-cylinder, 42-horsepower motor is mounted considerably in front of the two driving wheels which are over 6 feet in diameter and provided with traction blocks. The driver sits on the plough and alone attends to driving, steering and regulation of the ploughshares of which there are six. At the extreme rear a single steering wheel serves to determine the depth of the ploughing (apparently by adjustment of its height in relation to the plough frame), while the driver seems to be able to raise each individual share from his seat. The width of the work is about 5 feet and the machine is capable of turning over from 2 1-2 to 3 morgen (a morgen is 0.631 acres) of land every hour at a depth of 30 centimeters (12 inches), and the fuel consumption is figured as 4 kilograms (5.7 liters) of gasoline per morgen, which equals 2.06 gallons per acre. The price of the machine is 15,000 marks and it is said that it works well on hilly ground while still leaving something to be desired where deep ploughing of very heavy soil is wanted.—From *Automobil-Betrieb*, Oct. 15.

More Buses in London—Ten automobile omnibuses form the average weekly addition to those already in service on the streets of London. Cab horses are being sold off at the rate of 200 every two weeks, and within the next year it is believed that the horse will be entirely supplanted by the motor bus. The latest available figures show about 1,500 buses in service and 1,600 horses.

The Runabout as an All-Winter Car

WHEN a number of automobiles form the complement of a private owner, that justly popular and handy type of little car known as the runabout is sure to be included. When it is the only car in the owner's garage it is frequently compelled to do duty usually reserved for larger cars. It is in its character as an all-round car that this article has to deal. The runabout is essentially a car for the business man's personal use; the ever-ready means of locomotion for the physician, while for suburban use it is made to do all kinds of work, from hauling baggage to and from the station, to carrying its owner and his family to an evening reception.

With the modern runabout the power is generally in excess of the actual requirement, and there is no good reason why an ideal Winter car cannot be made of it by the addition of a complete coupé body, or by adding the necessary upper structure to the body already on the car in order to get the coupé effect. The additional weight will range from 200 to 400 pounds. Some excellent effects can be arrived at if care is exercised in changing a runabout to a coupé. The design should be harmonious with the original parts of the body, and in changing the car it should always be borne in mind that when Summer comes around again the body must be put back in its original shape.

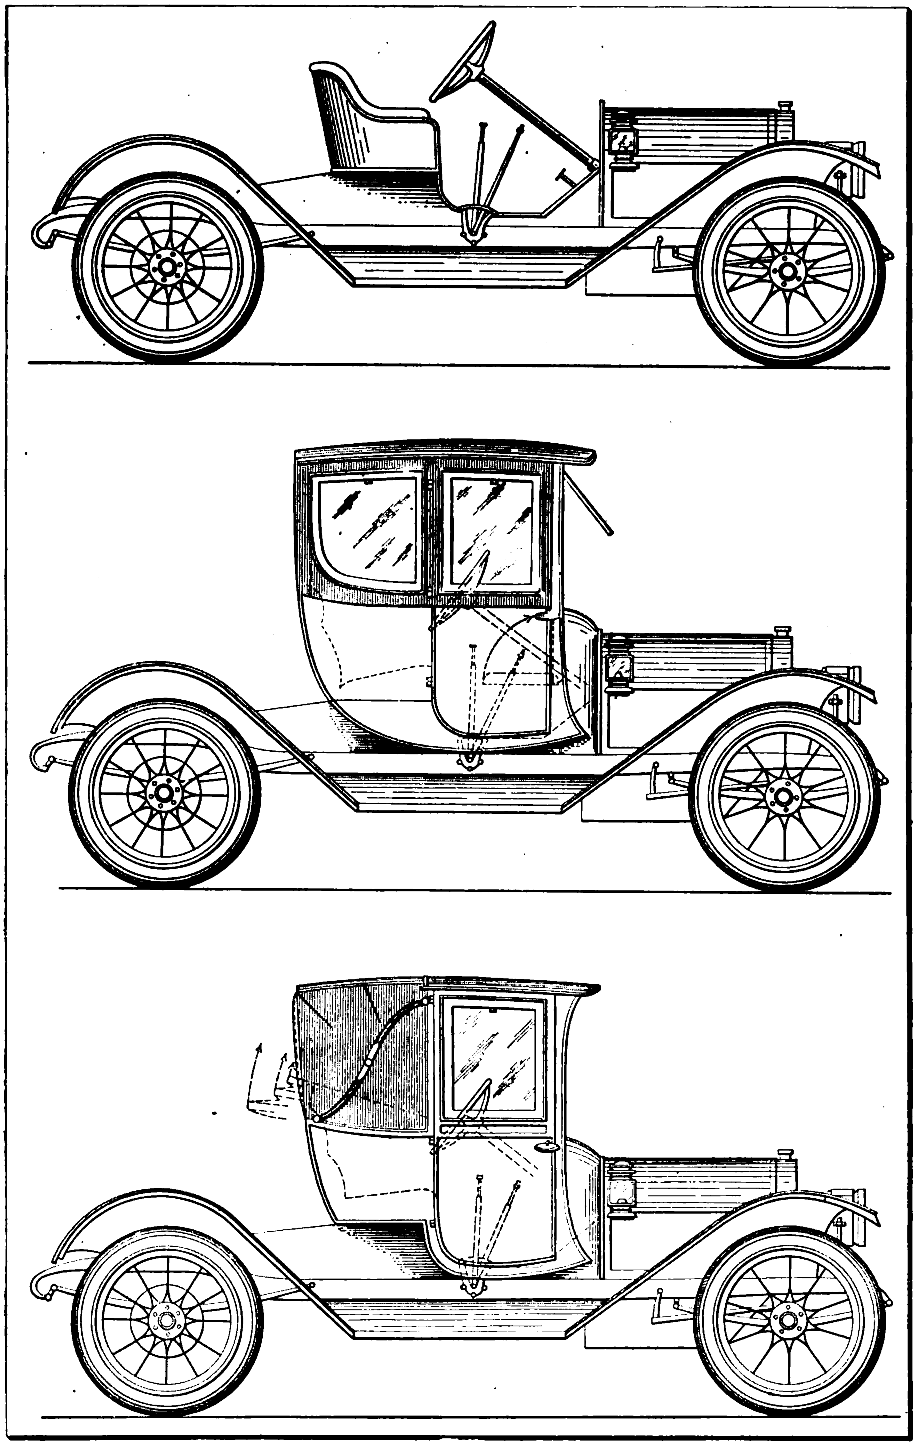


Fig. 1—Showing an ordinary type of runabout with open body
Fig. 2—Same car with seat removed and fitted with a coupe body
Fig. 3—Semi-collapsible landaulet body fitted to the same car

The method employed to effect the change is illustrated on two styles of runabout bodies, three designs being set forth. In Fig. 1 is shown an ordinary runabout body, while in Fig. 2 the same car is shown with the seat removed and a coupé body placed in position. The place that is left free by the removal of the seat is the principal support for the coupé body, the width of which is such that the sides come over and outside of the runabout body and enclose the levers. The dash is of one piece with the body, the original dash being removed. At the rear the coupé body fits close down to the deck, and at the lower part of the sides a metal strip is fastened to the coupé rocker, extending in to the runabout body and closing up any gap through which cold air might otherwise enter.

The coupé is really an envelope over the runabout chassis, the doors permitting of easy entrance from either side, while the glass frames can be made to drop if desired. It is recommended, however, that the door glass only be made to drop and the front glass made to swing outward in order to get the rain visor effect. The side and rear glass frames should be stationary to insure protection against cold and possible rattling. There is ample seat room for two passengers, while a fold-up emergency seat could also be installed, the latter being on the left side only. When in use its occupant sits crosswise of the car and leans against the door; when not in use the seat folds up under the cowl as indicated by the dotted lines in Fig. 2. The body as illustrated in this figure has upper panels of wood, the lower panels being of metal. The framing is also of wood. It should be made as light as possible, not only to facilitate removal and replacement as the seasons change, but also to prevent overloading of the car, excess weight for a body of this description being in the nature of a crime, for it must be remembered that, especially in the rural districts, the service demanded of the transformed car calls for long trips over roads which are at their worst when the car is most needed.

In Fig. 3 is shown another type of body that can be fitted to the runabout shown in Fig. 1. It is a semi-collapsible landaulet, and the rear part of the top falls as indicated by the dotted lines and arrows. When not in use this top leaves the body open from the back of the door. The dimensions of the body and the seating will be the same as in Fig. 2; the door frames can be dropped, and the front glass frame raised to secure proper ventilation when the weather is not too inclement.

The possibilities of body designs that can be grafted onto the runabout are limited only by the will of the owner. Almost any design can be made to look well, but the best effects are gained where the entire body is put on as illustrated in Figs. 2 and 3.

In Figs. 4 and 5 are shown a regular fore-door runabout before and after the imposition of an upper structure that converts it into a coupé for Winter use. In this combination design the entire lower body remains, the upper or cab part being built to conform to the shape and design of the original body. It is attached at the top line of the seat door and cowl. The door is made continuous by this joining, and the two parts are made to work as one. The hinges must be in perfect alignment, and the regular lock on the lower part is fitted with an outside handle.

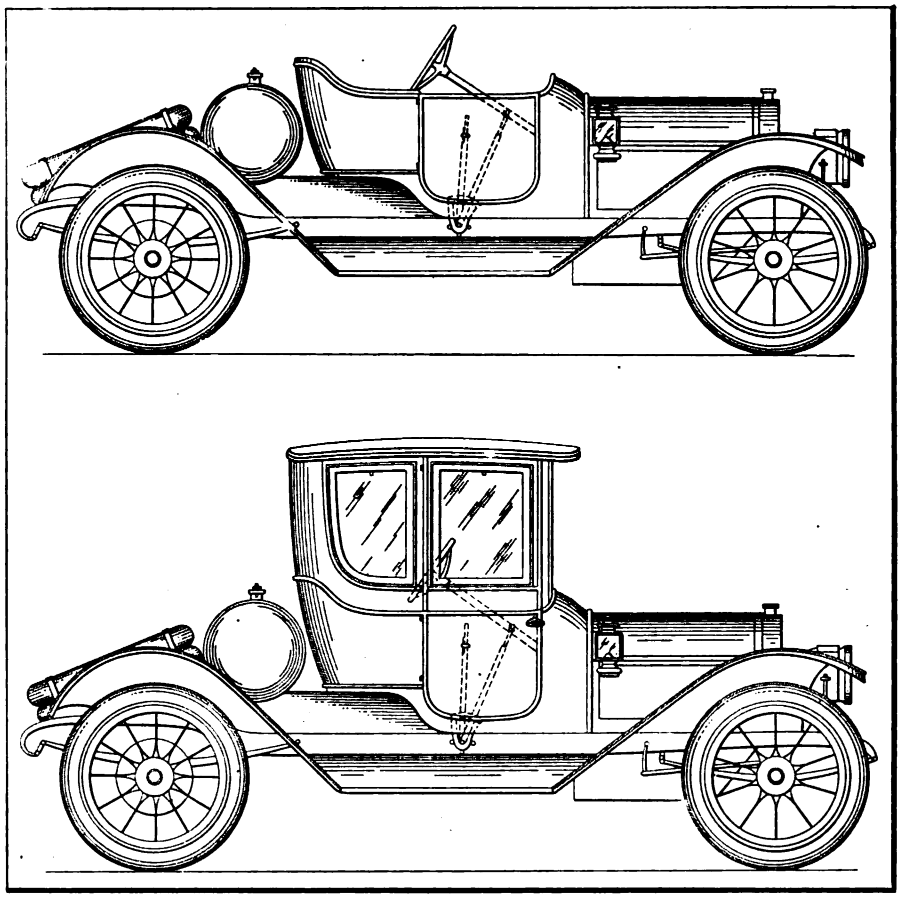

Fig. 4—Ordinary type of fore-door runabout for warm-weather use
Fig. 5—Same car after upper part has been added to convert it into a coupe

In making this upper structure care should be exercised to have it conform to the shape of the lower body; in fact, it is hardly possible to make it except by using the lower body as a pattern. It is constructed of a light wood frame with aluminum panels and mouldings. The side and rear glass frames are stationary, but the front glass can be swung out, as is the usual custom with closed bodies, and the door glass can be lowered a few inches for purposes of ventilation.

The seat room for passengers should be about the same as that allowed in Fig. 2, and the use of a small fold-up seat is generally an advantage in all bodies of this type. The finish of the upholstery and the inside trimmings should conform to that on the runabout as it came from the factory, but it should be as light and as plain as possible on the new part of the body. The trimming on Figs. 2 and 3 should be of cloth, this material being much more comfortable for Winter use.

There are now on the market several other methods of converting an open-body car into a closed one—by the use of curtains, for instance—but the most satisfactory arrangement is something along the line illustrated, as this gives a substantial enclosure that will resist rain, and that will allow of entrance and egress without sliding under dripping curtains.

Europe's Governments Subsidize Automobiles

Continental European Governments are taking a deep interest in the development of the automobile, a fact which gives great encouragement to manufacturers. This applies particularly to motor trucks, the owners realizing that if they would obtain a subsidy, they must maintain and operate the trucks in such a manner as to get at the accurate cost of such work. Besides, owing to the subsidy in question, manufacturers are careful to build their motor-trucks under direct supervision of technical representatives who are assigned by the War Departments of the respective countries. The respective Government then contributes a sum equivalent to $1,000 for the initial purchase of the car, $250 yearly, for five years, towards the operation and maintenance of the truck which will be turned over to the government in the event of war.

Mexico Doubles Automobile Imports

The demand for foreign-made vehicles of various kinds is rapidly growing in Mexico, as is shown by the annual report of importations which has just been issued by the federal government. During the fiscal year 1910-1911, ending June 30, vehicles were imported to that country to the value of $9,062,679 as compared with $5,754,194 for the preceding fiscal year, an increase of $3,308,484. It is claimed that but for the revolutionary disturbances which caused a general suspension of business for several months the importations for the last fiscal year would have been much larger. The present year promises a very material increase. The growing values of the vehicle importations is due largely, it is said, to the increase in the demand for automobiles. While these cars are purchased largely of American manufacturers good orders are constantly going to Europe.

Digest of the Leading Foreign Papers

Flame Leaks and Their Causes

ON the first Prince Henry Tour in Germany in 1910 one of the cars belonging to B. von Lengerke, an engineer, took fire while going at full speed and its owner took pains not only to examine into the causes of the occurrence, but also to look up the circumstances attending all other fires affecting automobiles and aeroplanes which came to public notice thereafter. He arrived at the result that in by far the greatest number of instances the carbureter bore the blame, or at least was instrumental in propagating the flame and igniting the grease and lubricating oil usually allowed to accumulate in greater or lesser degree in the drip pan under the motor where a fire is particularly difficult to extinguish.

Relating the result of his investigations the author states that a considerable number of aeroplanes have taken fire when the motor was started, in addition to those well-known instances where it broke out while the aviator was in flight, and in all these cases the cause can have been none other than a tongue of flame slipping out from one of the combustion chambers and reaching the vapors in the carbureter. All the causes which may be assigned for this occurrence may be generalized as one, namely, the momentary failure of the inlet valve to lock the fire within the cylinder. Ignition may take place before the inlet valve has been closed, or the inlet valve may be opened before the exhaust has been completed and while flame-hot gases are still present in the cylinder head.

This may be due to a momentary sticking of the inlet valve, or else to a peculiar design of the cams, meant to reduce valve noise in high-speed motors, in conjunction with over-advancement of the spark, and in this connection it is worth noting that carbureter fires were very frequent on the Prince Henry Tour of 1910, in which scarcely any cars participated that were not equipped with motors with a very high number of revolutions per minute, and that these occurrences were explained, not only by the author but also by other professional automobile engineers of high standing, as due to the extreme reduction of the time intervals between the motor periods, in some instances amounting to overlapping. At 2,400 revolutions per minute or more, designers experience the greatest difficulties in providing for precision in the reciprocating valve movements, as perfectly well known, and every factor which may retard or obstruct these movements may lead to the liberation of a tongue of flame.

As other possible causes for the phenomenon, leaking valves and sudden defaulting in the gasoline supply may be mentioned. A clogged jet, for example, may cause a very weak mixture whose ignition and combustion are likely to be so much delayed that the explosion period of the motor will blend into the exhaust period, with the consequence that, at the end of the latter when the inlet valve is again opened, high-tension gases still remain in the cylinder head.

With reference to fires which have been occasioned by starting of the motor, it is evident that the backfiring which is by no means uncommon when motors of high power are started (though the explosion may be weak) may send a small flame out through the inlet valve which has been reopened through the reversal. On the other hand, the induction of a poor mixture—usually accompanied by a pop—and the retarded combustion of such a charge, with the consequences already referred to, may, of course, occur at starting as well as at other times.

That similar effects may be produced through unintentional ignition is perhaps self-evident, and it is not only conceivable but it has been repeatedly proved that such untimely ignition may be caused by defects in the ignition device. The popular notion that fires are often due to leaks in gasoline ducts or to poor insulation of the electric wiring can, on the other hand, in nine cases out of ten, not be substantiated.

A flame from the inlet valve ignites naturally first whatever ignitable mixture may be present in the induction pipe and in the carbureter and then attacks any combustible substance which may have been precipitated around the jet. Now, if there are corners, corridors or cavities in the carbureter where fuel can accumulate to any extent—and a surplus discharge from the jet or jets may be due to violent bumping of of the vehicle or irregularity in the nozzle action—the possibility always exists that the normally harmless carbureter fires may be carried by a current of air and in the form of burning drops of gasoline to combustible substances in the drip pan.

These gathering places for precipitated fuel which therefore constitute the chief cause of fire risk are found in the majority of carbureters in which the air channel extends at right angles with the jet, but in some instances the designers of carbureters of this type have realized the danger and have taken special measures for circumventing it. A simple expedient for the avoidance of such accumulations, and one employed especially in carbureters in which dashpots and slides are among the features of design, consists in a drain hole at the lowest place, but this provision is after all only a makeshift, for if a carbureter is inclined to slopping with the gasoline at certain motor speeds it is easily possible that a flame could ignite a drop of gasoline which was just trickling down through the drain, thus carrying a conflagration even more rapidly than usual down into the vapors and oil puddles underneath; and if this happens either a good fire extinguisher or a mass of loose sand, right at hand, is required for averting damage.

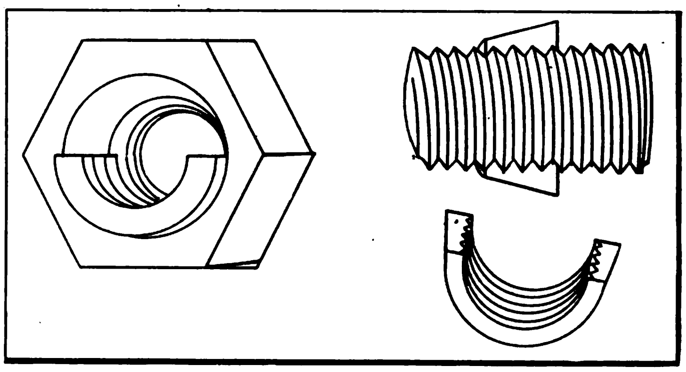

Fig. 1—Locknut for short bolt—a British improvement

The author closes his diagnosis of the possible causes of fire leaks from the cylinders of an internal combustion engine with remarks intended to obviate any exaggerated apprehensions on the part of automobile users, while admitting that he now always carries a fire extinguisher himself when going out on a trip of some length. And, he adds, he would rejoice if designers of carbureters would take pains to remove the objectionable feature to which he refers. Manifestly his facts and arguments also bear upon the leading issues: Slide valves versus poppet valves and long stroke versus short stroke, the long stroke giving longer intervals between valve actions for a given piston speed.—From *Der Motorwagen*, Oct. 20.

A Good Lock for a Short Bolt—Where a bolt is to be secured the locknut shown in the drawing, Fig. 1, affords, it is claimed, perfect protection against even such vibration as may loosen the customary combination of washer nut, jam nut and split pin—by shearing the pin or stripping the bolt thread—and it makes possible a shorter bolt than may ordinarily be used, resulting in a neat finish and in a minimum projection from the joined parts. The nut has a deep conical bore into which is seated a split nut the exterior surface of which is turned with a corresponding taper. It is apparently the split nut which abuts against the joined part when the main nut is fully tightened, while the small end of the split nut abuts against a shoulder in the main nut. It is said that the grip of this nut is strong even on a bolt whose thread has been partially stripped, owing to the wedging action of the conical surfaces.—From *The Commercial Motor.*

Water Tube Joints—A neat device for making and remaking of the flexible joints of the water circulation system, between the radiator and the motor, consists in a ring with knurled external flanges A. A. and an oblique transverse slot B as shown in Fig. 2. Two of these rings clamps are required for each joint, being fitted one to each end of the rubber tubing F, which is used for connecting the metal pipes. The ends of the rubber tube must be cut off squarely, so that the ring may be turned around on its seat with its retaining flange C rubbing against the end of the tubing. The joint is made with the aid of a length of tape D, the end of which is inserted in the slit till caught between the rubber of the tube and the interior cylindrical surface of the clamping ring. The latter is now turned around and draws

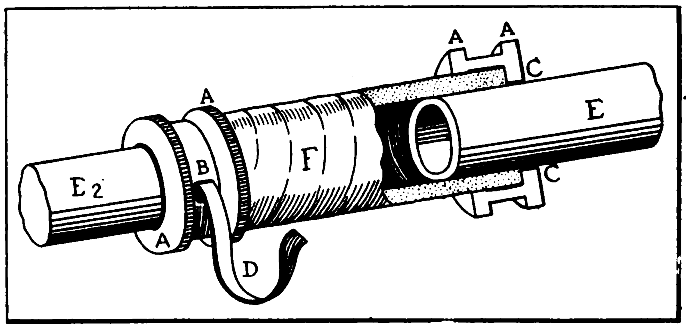

Fig. 2—Neat water tube joint—clamp at one end shown in section.

the tape with it squeezing it harder and harder against the tube the more of it is drawn in, and consequently at the same time squeezing the rubber tubing against the metal pipe E. As the circumferential pressure obtained by this method is very even, it is not necessary to screw the ring up very tight to get a joint which holds. The tape is now cut off and a slight additional twist is given the ring to remove the tape from sight. To unmake the joint, the ring is simply turned in the opposite direction, the tape always appearing through the slot, unless it has been turned in too far.—From *The Autocar*, September 23.

Fused Silica for Plugs and Goggles—One of the Cantor lectures organized by the Royal Society of Arts of Great Britain had for its subject: "Rock Crystal; Its Structure and Uses" and was delivered in May this year by Alfred E. H. Tutton, M. A., D. Sc., F.R.S. It dealt largely with the intensely interesting scientific and artistic applications of this substance whose field of usefulness for laboratory work, optical instruments, including spectacles and microscopes, and various practical purposes has been immensely enlarged since it became possible by means of the electric furnace and the oxy-hydrogen flame to fuse it in quantities and to produce from it articles of almost any desired form and size.

The fused quartz thus produced has been found to differ from the rock crystal of nature in many important properties. When, for example, quartz of a specific gravity of 2.651 is fused, the solidified cooled quartz glass has only the specific gravity of 2.21, and the coefficient of expansion, though almost imperceptible beforehand from any viewpoint but the scientific one, is also reduced to the vanishing point. While rock crystal is slightly brittle and subject to fracture from mechanical violence—though not from changes of temperature—the fused quartz is so tough that an article made from it is seldom broken or chipped when dropped on the floor.

The possible use of fused quartz for spark plugs and perhaps even for the interior lining of motor cylinders or rotary internal combustion engines seems to be foreshadowed in the qualities of the substance, so that the subject gains at least a speculative interest, also from the standpoint of the automobile user and manufacturer.

An excellent and immediate test by which quartz may be told from common glass is derived from its coldness to the touch. Spectacle makers are well known to discriminate between ordinary glass lenses and the so-called "pebble" lenses made from Brazilian quartz pebbles by the cold feel of the latter when placed on the tongue. This property is ascribed to the high thermal conductivity of the quartz, which is combined with almost absolute refractoriness to electric currents, making it an excellent insulator. It is almost unbreakable, withstanding changes of temperature which would at once shatter glass, and it is far less readily attacked by acids excepting hydrofluoric, than either glass or porcelain. Its elasticity is well-nigh perfect and it can be wetted in contact with water only with the greatest difficulty; which would recommend it for driving spectacles and goggles. Quartz begins to soften at a temperature of 1,500 deg. to 1600 deg. centigrade, in the neighborhood of the melting point of platinum, and can be worked by skilled men at a temperature somewhat higher. Fused silica glass articles are now being manufactured by two British and two German firms.—From *The Journal of the Royal Society of Arts.* Oct. 27.

Solidification of Gasoline.—In discussing means for reducing the fire risk in aeroplanes, the technical committee of the Automobile Club de France recently approved a proposition made by a military member to the effect that a competition should be organized for judging the merits of various methods for absorbing gasoline in some solid substances which will give it off in vapor or otherwise when exposed to a current of atmospheric air.

The German experiments were cited by which gasoline has been turned into a firm transparent jelly, capable of being cut into blocks and handled with tongs and other tools, by treatment with stearic acid, hydrochloric acid and caustic soda; and also the methods used, particularly in the United States, for absorbing large volumes of acetylene gas in porous solids. Finally it was recalled that the Society for Saving the Shipwrecked last year had requested the club to experiment at its laboratory with a tropical wood called Bolandero said to be capable of absorbing large quantities of gasoline, and that it had been found that this wood in reality does absorb 210 grammes of gasoline in 52 grammes of its own weight and retains it under a mechanical pressure of up to 0.219 kilograms per square centimeter of its surface, whereafter it exudes.—From *Bulletin Officiel*, September.

The Lubricating Oil can be Burned Smokelessly just as well as the gasoline, but much more air is required for this purpose than for burning the gasoline alone. The great art is to get along with as little oil as possible, so that there may be oxygen enough in a cylinderful of air for complete combustion of the gasoline charge as well as the oil. Most automobilists, when the motor acts sluggishly, by reason of over-oiling, turn on more gasoline, while they should turn on more air and reduce the oil feed.—*Automobil-Betrieb*. Oct. 15.

Letters Answered and Discussed

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

Mixture Too Rich

EDITOR THE AUTOMOBILE:

[2,908]—I have a 1191 car. When it runs slow up to 12 miles an hour it pulls fairly well, but when I open the throttle wider it starts to miss. I have examined the intake manifold for an air leak and also have had several experts try to adjust it, but they do not seem to help it any. When I stop the engine, gasoline drips from the carbureter for about a minute, then stops. Would you kindly tell me in your next issue what the trouble is and how to fix it? G. W.

Albany, Wis.

Evidently your carbureter is out of adjustment and you are getting too rich a mixture; that is, there is too little air in proportion to the amount of gas in the charge which is admitted to the cylinder. It may be that the air inlet is clogged with dust or grit, or that the tension in the air valve spring B, Fig. 1, is too great. First examine the air inlet for dirt, then adjust the air valve by means of the thumb screw A. This adjustment should be made while the motor is running at a moderate speed, the screw A being turned until the best motor performance possible is obtained. After doing this try reducing the size of the spray orifice slightly by means of the adjustment provided for that purpose, as it may be that the opening is too large, causing the slight flooding which you mention.

All such carbureter adjustments should be made carefully and systematically. On page 587 of our issue of October 5, 1911, will be found general directions for performing them, which may be of service to you.

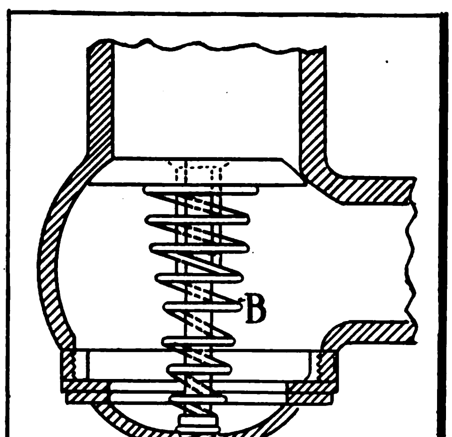

Fig. 1—Section of carbureter showing air inlet valve

Cleaning Reflectors

Editor THE AUTOMOBILE:

[2,909]—How can I repair the reflectors of my auto searchlights? They seem to have become dull from the heat of the flame. Can I get a ready-mixed preparation and apply it myself, or must I have new reflectors? I am a constant reader of your magazine and would appreciate any information you can give.

Holstein, Ia. A. W. SCHMIDT.

If your reflectors are not too badly smudged up you may be able to clean them with alcohol. In case this does not remove the dullness the best thing to do would be to replace them.

Anti-Freezing Solutions

Editor THE AUTOMOBILE:

[2,910]—Will you please tell me how much calcium sulphide to use per gallon of water and will it do any harm by standing in the radiator? This is used as an anti-freezing solution. W. B. WHITE.

Zelienople, Pa.

The use of the chemical which you mention for the purpose is not recommended. We are of the opinion that you mean calcium chloride, which makes a very good anti-freezing solution. The water in this solution, however, evaporates, and about once a month the specific gravity of the mixture should be checked up because if allowed to become too strong the calcium chloride will precipitate and clog the cooling system.

The best way to make the solution is to first make a saturated solution of the chloride, and then add water to it until the desired mixture is reached. This is done by taking half a gallon of water to eight pounds of chloride for each gallon of saturated solution required. It is a good idea to make a gallon or so extra to have on hand. You can tell if this makes a saturated solution by observing if some of the crystals remain in the bottom undissolved. If this is not the case add more crystals until some of them will not dissolve. This solution is made applicable to the cooling system by adding to it more water, and finally, when the right proportion is obtained, a handful of lime to render it slightly alkaline. The latter is done because this solution is said to have an acidic action on the metals of the whole cooling system. As the latter has been proven, the simple precaution of adding the lime will counterbalance it.

Fixing a Damaged Radiator

Editor THE AUTOMOBILE:

[2,911]—Apropos of the series of "Best Repair" articles you have been publishing, my experience with a damaged radiator should prove interesting to some of your readers.

A small boy threw a stone while I was traveling at about 20 miles per hour and hit my honeycomb radiator. The cost was a new radiator, but that would not get me home and I had several hundred miles to travel on very important business.

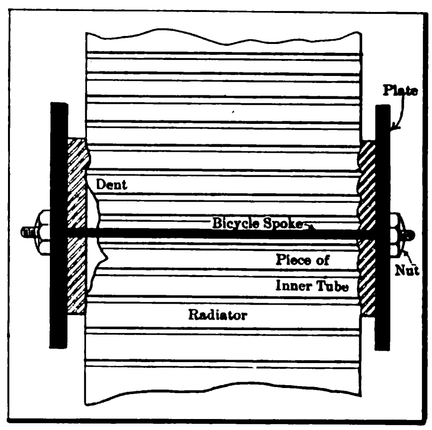

Fig. 2—Showing how a honeycomb radiator can be temporarily repaired with a bicycle spoke, piece of inner tube and a piece of metal

The nearest village of any description was 2 miles away, and I found that there was a bicycle repairer there. I had an old inner tube in the car and proceeded as follows: I cut two pieces of rubber from the tube about twice as large as the dent and with the aid of two pieces of wood placed back and front of the radiator and some rags interposed between the rubber pads and the board I managed to bind the board together with copper wire.

Needless to say this did not hold water very long, but it served long enough to get 2 miles without losing all the water.

Fig. 2 shows the method I employed of executing a repair, which carried me to my destination without further trouble, and for several weeks afterward. I located the repairmen and had him cut a bicycle spoke to the length indicated by me, which was sufficient to pass through the radiator. One end was already threaded and he threaded the other end. The illustration speaks for itself. Tightening up on the nuts compressed the rubber of the inner tube over the orifices of the tubes and was entirely satisfactory.

I treasure the part even to this day and I carry them on the car in case I ever have a leaky radiator tube again.

Removing Tight Wheels

Editor THE AUTOMOBILE:

[2,912]—Will you kindly tell me through your columns the best way to remove the rear wheels of my car? I have made several unsuccessful attempts to get them off, but since they are keyed to the axles and I have no wheel remover it appears to be a hopeless job. Any suggestions which you can offer will be appreciated.

Buffalo, N. Y. M. E. ROWE.

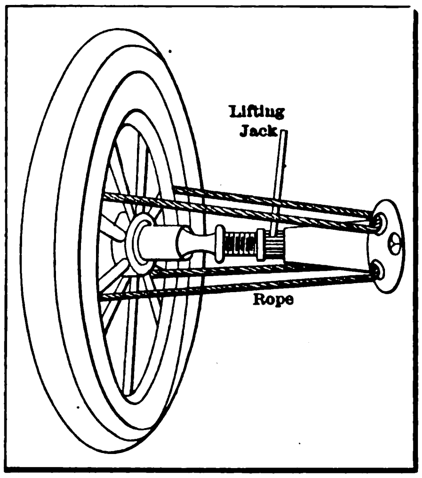

Fig. 3.—Method of removing tight wheels

Wheels may be removed by following the procedure illustrated by Fig. 3. The hub cap is first taken off and a stout rope is put around four of the spokes as near to the brake drum as possible. Then a lifting-jack is screwed down to its smallest length and placed with its head against the axle, or, as is shown in the illustration, the head is placed against a block of hard wood which touches the axle. The rope is then fastened around the base of the jack and when the latter is screwed up the wheel should come off without any difficulty.

Cleaning Carbon Deposits

Editor THE AUTOMOBILE:

[2,913]—When the cylinders become dirty with an accumulation of carbon, grease, etc., what is the best and quickest method of cleaning it out? Can it be burnt out without damage to the engine? If so kindly tell me just how this is done.

H. T. OFFTERDINGER.

Washington, D. C.

The surest way to get rid of carbon deposit is to remove the cylinders from the crankcase and then to scrape off the accumulation with a hard, sharp-edged tool, being careful not to scratch the cylinder walls during the operation. At best, this is a rather long and tiresome job, but the improvement in the power developed and in the running of the engine afterward will compensate for the work expended.

Kerosene, or, better still, some of the so-called carbon-removing compounds, will remove the softer part of the deposit, at least. Some of these will dispose of even the harder formation also, thus cleaning the cylinder quite well. Kerosene does not generally remove the hard carbon, although if allowed to stand in the cylinder over night it becomes more effective. In using the prepared carbon removers which are on the market the directions for their use will be found accompanying them. The accumulation cannot be burned out of the cylinders.

Making Auxiliary Air Port

Editor THE AUTOMOBILE:

[2,914]—Will you please illustrate in your columns some method for rigging up an auxiliary air port apparatus which will be adjustable from the driver's seat? A friend of mine has applied such an adjustment to his car and I have been wondering if it would be possible for me to do the same thing, as it seems to add greatly to the power of his car on hills.

Neoga, Ill. MECHANIC.

An apparatus which has been successfully used for the purpose is shown by Fig. 4. This gives a very good hand control of the extra supply of air and leads to fuel economy. The valve is placed in the intake manifold as indicated. The sketch is self-explanatory.

Storing Cars in Barns

Editor THE AUTOMOBILE:

[2,915]—I had intended to store my car for the Winter in a country barn within which horses are kept. A friend called my attention to what he termed the fact that, owing to the proximity of horses, it would mean the ruin of the paint and varnish upon my car. He was so positive about it that I hesitated very much about carrying out my plan. Have you ever heard of such a thing? And, generally, what do you advise? It is not a question of cost, as the barn is no less than a garage, but I am sure of care and perfect protection in the one case and extremely doubtful about it in the other. GEORGE E. HYATT.

New York City.

The varnish on an automobile is very sensitive and unless the barn in which you are contemplating storing the car for the winter is light, airy and free from dampness, we would not advise your placing the car there for such an extended period.

Coal gas and gas which sometimes percolates through heating pipes will in time cause a very bad form of spotting. Ammonia gas which is of common occurrence

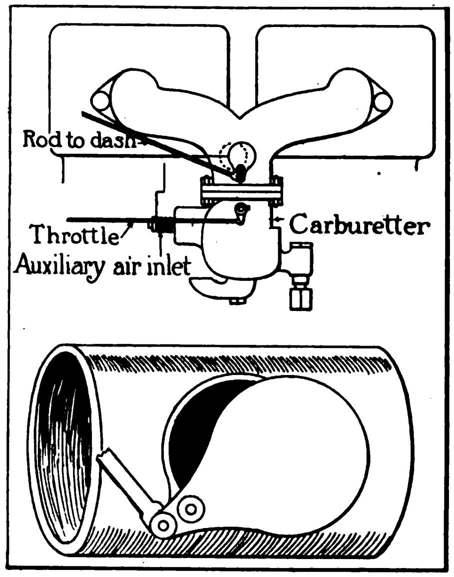

Fig. 4—Hand control of auxiliary air valve

in stables and barns is also known to be injurious to the varnish. The form of spotting here mentioned may be recognized by the dull, lustreless spots, showing a film of greasiness which afflicts the surface. Damp and ill-ventilated garages are the cause of a great deal of this spotting, which is very difficult to remove. Pure, fresh air brought into the storage quarters of the automobile in a sufficient quantity to counteract the accumulated foul air, fetid odors and gases, will, however, generally prevent spotting and loss of luster.

In storing automobiles in places such as you mention, it is therefore advisable to have the quarters well ventilated and lighted; also to cover the cars with suitable cloth covers, thus preventing a great deal of dust and dampness from reaching them. In general it might be added that the average barn is not suitable for the storage of a valuable automobile.

Regarding Acetone

Editor THE AUTOMOBILE:

[2,916]—Can you offer me through your columns information concerning the composition and nature of acetone, and is its use and manufacture controlled exclusively by patent rights? J. W. TAYLOR.

Atlantic City, N. J.

Acetone is a well-known volatile, liquid chemical compound with the formula CH_3COCH_3. It is usually obtained by the distillation of certain acetates, such as starch, gum or sugar, and is used to dissolve many organic compounds. The use and manufacture of acetone except in connection with certain manufacturing appliances used by acetylene gas makers are not controlled by patent.

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

TOOLS FOR TESTING WORK—Few tools in the shop are of more use than try-squares and the various forms of spring calipers. Calipers are employed where the accuracy of the measurement will not permit of the use of ordinary steel scales or rules. Micrometer calipers and standard or limit gauges must of necessity be applied in cases requiring extreme fineness of measurement, often being used to get results as close as .001 inch or less. A delicate touch and good judgment are essential to skilful manipulation of all forms of calipers.

Fig. 1 illustrates the various types of these tools and their application to the work. At A are shown what are called keyhole calipers, these being used to measure from the side of a hole to the edge of the work; inside calipers are represented at D; outside calipers at C, and at B are seen a pair of spring dividers. Keyhole calipers are also of use in measuring the throw of a cam, the thickness of the shell of a tube, or in determining whether or not the hole in the work is central. The manner of using the other forms is obvious. In using spring dividers, after locating the center, incline them slightly in the direction of revolution and describe the circle. Be sure that the surfaces to be measured are perfectly clean before applying the calipers. This is especially important with the finer measurements. In making very large circles, for spacing and the like, extension dividers or trammels are used. For all ordinary work in the repair shop measurements can be made with a steel scale. These are accurate, and when skillfully used are second only to micrometer and vernier calipers.

Try-squares have several very well known uses, among them being to test for squareness of stock such as B in Fig. 4. In this connection it might be mentioned that D is the try-square proper and C the "beam." When testing for the flatness of surfaces, hold the try-square and the block B up to the light and tip the blade toward you so as to form a line contact between the two surfaces. If no light shows along the blade of the square, the surface is true. A bevel-edged square is sometimes used to get this line contact for fine work. This is shown at D, Fig. 2. To make sure that a surface is absolutely plane it should be tested both along its length and width and diagonally.

BOLTS REQUIRE ATTENTION.—It is frequently the case that after traveling over cobblestones or other rough roads nuts will jar loose even if fastened by means of a lock nut. A split pin or castellated nut should always be used if the position allows of this practice. In placing a nut upon any part of the motor with a long wrench or spanner it must always be remembered that some day it will have to be removed. With a long leverage immense turning force can be applied to a nut, but it is not necessary to exert the fullest strength of which a man is capable in placing a spark plug in a cylinder or tightening a hub cap nut.

Rust is often a factor in preventing the removal of nuts which have been subjected to moisture. In this case the application of a little heat, either from a gasoline torch or from some gasoline which has been soaked up in a piece of cotton waste and wound about the joint, will aid the refractory member. Prevention in any case is better than cure, and if the thread is coated with graphite before tightening it will always be easily removable and will never give any trouble in the direction of rust.

The wise automobilist will generally carry one or two bolts and nuts of the size most used in his motor, if he be going on any extended trip where garages will not always be in reach and there is a likelihood of repairs having to be made upon the road.

OVERLOADING THE CAR—It is evident that the average passenger automobile, which is designed primarily as a vehicle of pleasure, should not be overloaded. A five-passenger touring car of medium weight is perfectly capable of taking care of all the baggage a party of five need take on a trip of ordinary length. But when this limit is stretched and the car on its way

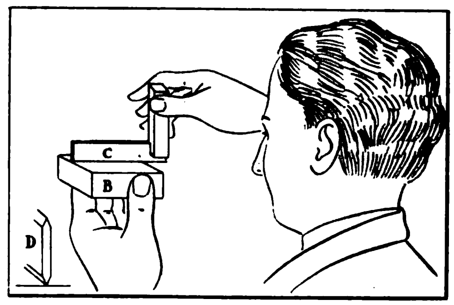

Fig. 2—Testing the flatness of a surface plate with a try-square

through the country has the appearance of the old-fashioned ship of the desert it cannot be reasonably expected to perform its work with any degree of comfort to the passengers. The springs and suspension of the car are designed for a given load, and a certain percentage is allowed as a factor of safety and to take care of any reasonable amount of overload. But a very uncomfortable vehicle can be made of the best of cars by overloading to such a degree that the shocks which are given by the irregularities of the road surface are transmitted directly to the occupants of the car.

In loading the car compactness must also be made an object, not alone for convenience of the occupants, but to insure the easy riding qualities of the car itself. It is therefore advisable for the occupants of a car when starting on a tour to remember that it is of great importance to carry as little as possible, and to carry that little compactly.

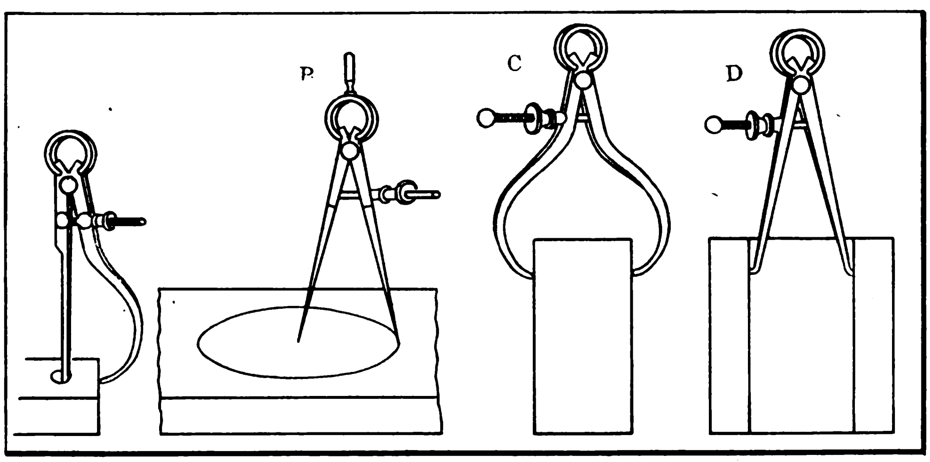

Fig. 1—Illustrating the different types of calipers and their typical uses in making accurate and necessary measurements

HAMMERS FOR SPECIAL WORK.—The ordinary flat-headed variety of hammer cannot be used for the various pieces of work which will arise and for which a special hammer must be called into requisition. Peening operations will require hammers of different shapes, depending upon the requirements of the particular case in point. As shown in Fig. 3, the heads of the hammers will be formed so that when it is desired to indent the metal or bend it to a certain form the work may be much shortened by the use of the correct hammer head.

The ball peen as may be seen by its shape is not so much for lumping the material as it is for spreading it and hence thinning it out in the vicinity of the point at which the

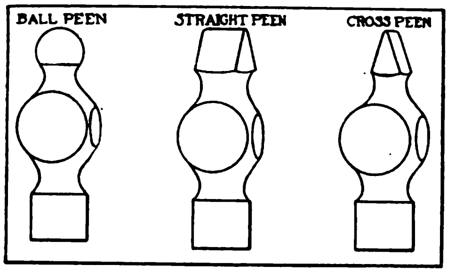

Fig. 3—Three different shapes of peening hammer heads

blows are directed. The cross peen and straight peen heads may be used interchangeably as the difference between them lies in the fact that the lines of direction of the heads are at right angles to each other. They are designed for the purpose of beating the metal into varying thicknesses or in some cases for spreading it about a given point.

TEMPERATURE OF COOLING WATER—The temperature of the cooling water will vary under different conditions under which the car is running. In mounting a hill with throttle open and retarded spark the charge will be much more slowly burned and the cylinder will have far less chance to be cooled between explosions. This will result in heated cylinder walls and hence in much warmer water. It is not an uncommon thing to have a steaming radiator after climbing a long steep hill on high gear.

In running along a level road the temperature of the cooling water ought not range much above 180 degrees Fahrenheit, so that when it is necessary to negotiate rough or hilly country there will be a sufficient margin before reaching boiling point to allow for any of the changes in temperature which take place. In Summer there will also be a marked tendency for the cooling water to become overheated on account of the air which is drawn over the radiator being so warm that it has very little cooling influence. In Winter the problem is entirely different and becomes one of keeping the water warm enough. In many cases the motion of the car is sufficient to cool the radiator sufficiently for all purposes and the fan belt can then be detached so that it is not in use. A nicer way would be to have a fan which has a variable pitch, so that it may be regulated to suit the requirements of the temperature of the locality and season.

It is not desired to cool the motor to a very great extent, as every unit of heat which is thrown into the cooling water represents a loss of power. Every gallon of cooling water which is raised 10 degrees in temperature in a minute represents the loss of approximately 2 horsepower. This seems like a very large quantity when it is considered how often the temperature of the cooling water rises and falls, and it is a large quantity, for fully one-third of the horsepower which is contained in the fuel supplied to the engine is lost in cooling the motor. It is therefore evident that it is a serious loss when too much of this heat is thrown away by having the cooling water at a higher temperature than is necessary.

USING CHIPPING HAMMERS—Every repair man and driver is familiar with the various types of chipping hammers. Nevertheless a few hints as to their use may not be amiss. Simple as the operation may seem, there is quite a knack in getting the most out of the hammer blow. The handle should always be grasped firmly near its end, so that the blow can be controlled, and the arm should be swung from the elbow. The chipping of metals is most commonly done when they are dry. Start with short, light strokes and increase to long and vigorous ones as the work progresses. When chipping out key-ways, grooves or slots, the chisel will cut better if wiped off occasionally with a piece of waste saturated with oil. When chipping a surface always fasten the piece in the vise horizontally, if possible, and use a packing block to prevent slipping. Begin the cut by holding the chisel parallel to the surface of the work and take off the first chip with a sharp blow. For succeeding cuts the chisel should be inclined somewhat. The manner in which the chips come off affords a means of determining the kind of metal that is being worked. If the material is hard cast iron the chips will fly off, while if steel or wrought iron they will curl up in front of the chisel. Chipping is rather a makeshift operation at best and should be resorted to only when no machine tool is at hand.

LONG BEARING A GOOD FEATURE—It is a serious fault to have bearings in a machine or any length of shafting of insufficient area to amply support the weight and other live strains which the shaft will be called upon to support. With the great tendency to save weight in the motor by various means the length of the various bearings should be well considered, and an intending purchaser should be careful in this respect, for it is of vital importance. There are certain rules for the dimensions and spacing of bearings which cannot be neglected, so that when the cylinders of an engine are cast

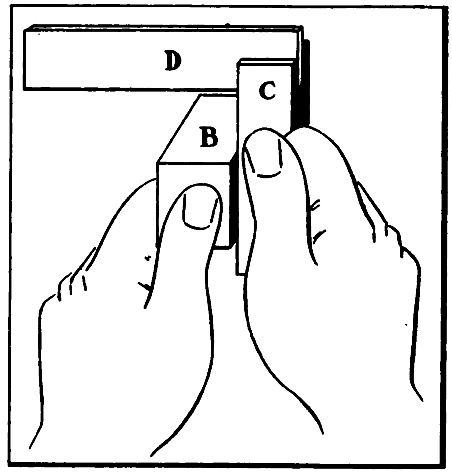

Fig. 4—Testing stock for squareness before using it in machine

in pairs the length of the bearings between the two blocks of cylinders must be sufficient to compensate for the greater length of shafting between bearings, or, what amounts to the same thing, the fewer bearings for the same length of shaft.

A shaft with a long interval between bearings will have a decided tendency to whip. By this is meant that the shaft will tend to form a loop in the same manner as when a string with a weight at the center is twirled about the two points of support at its ends. When this motion commences, it will gradually increase and result will be serious wear on the end of the bushings. Long bearings will go far in preventing this evil, but they are without the desired effect if they are not backed up by a shaft sufficiently thick to withstand bending stresses.

A shaft is classed in mechanics as a simple beam, and the calculations involved in determining the proper thickness of the shaft and the length of the bearings are amply summed up in formulæ which take into consideration the horsepower transmitted and the distance between supports. The maximum explosive force of the gas in the cylinder is taken as the working stress and a considerable factor of safety is allowed on account of the severe stresses to which the shaft may be submitted.

In a well-balanced motor the stresses on the crankshaft are so well distributed that the whipping tendency is reduced to a marked degree. This balance will go a long way toward eliminating the vibrations of the engine and will produce a smooth-running engine instead of a machine which rocks and tosses under unbalanced forces. The balance of the engine is maintained often by distributing the weight in the fly-wheel or in putting counter-weights upon the crankshaft so that all the large forces which are not directly connected with driving the motor are met by equal forces, which are caused by the revolution or reciprocation of these parts. Other and more complex methods of engine balance involve the changing of the connecting-rod angles. The efforts spent upon balancing the engine are well repaid, and make the engine no more costly to manufacture.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Reasonable $1,000 Ideal

EDITOR THE AUTOMOBILE:

I have read with much interest the letters you have been publishing describing the ideal cars of some of your subscribers and note that most of them run to large and expensive machines. Last year I drove a six-cylinder 40-horsepower touring car and a very light runabout. This year I am still driving the six, but exchanged the runabout for another popular-priced light runabout and cannot speak too highly of the faithful service, in all sorts of weather, that these little fellows have rendered, the one I have having averaged 1000 miles a month since March and having had but the slightest care. A considerable part of the distance has been cross-country work.

Based on experience with these three cars, I believe in a light, low-priced car if honestly built. It should have a 3¾-inch by 4½-inch six-cylinder, four-bearing engine developing about 30 horse-power. The engine and transmission should be a unit, with the cylinders cast together as in the Ford L-type heads with enclosed valves. The crankcase should have large hand holes with readily detachable covers. The thermo-syphon system of cooling should be used with a fan-bladed flywheel on the front of the engine, and a high-tension magneto with fixed advance and no batteries. The oiling should be by splash in the crankcase, the level being maintained by filling from time to time. A hand throttle on the steering wheel with foot accelerator works excellently. The clutch should be of multiple-disc type in an oil bath. There should be three speeds forward and reverse, sliding gear transmission with the control in the center of the car, one pedal to operate the clutch and service brake on the propeller shaft and another pedal to operate the emergency brake on the rear wheels with ratchet to lock same in position. The wheelbase should be 110 or 112 inches, with four full-elliptic springs, axles well braced and 34 x 3½ clincher tires.

The body should be of the straight type with relatively low seats, and a knapsack type of gasoline tank back of the rear ones. I have used both right- and left-side drive and have no preference. The rear wheels should fit on the rear axle on a taper with lock nut and key. Steering knuckles, yokes and connections should be of ample strength—they look very frail on most light cars. All shackles, spring joints, knuckles and the like should be fitted with little spring-covered oil cups.

All moving parts and accessories, such as oilers, pumps, fans, sight feeds, self-starters, complicated electrical work and the like, should be made as few as possible. Such a car as I have outlined should be flexible, light, with more speed and power than necessary, simple to operate and to keep in tune, and, if honestly built, should last a long time and give extensive service.

Based on the selling price of the host of little cars that are coming into the market, I should think "my car" could be sold for $1,000 or a little over. NOVICE.

Mineola, L. I.

Another Youngster's Idea

Editor THE AUTOMOBILE:

The following is a general outline of my ideal 1912 car: The engine should have four cylinders of the L type, cast singly, with copper jackets. The motor should have a bore of 5 inches and the stroke should be 8 inches with 2¾-inch valves. These valves should be enclosed so as to exclude grit. This construction will give full 40 horsepower according to the A. L. A. M. rating and on a brake test will develop about 75 horsepower.

There should be a five-bearing crankshaft and camshaft, the bearings being of bronze or babbitt metal. Lubrication should be by positive force feed, the oil being contained in a tank at the side of the motor with a sight feed on the dash. The ignition should be by two independent Remy magnetos with two sets of Bosch plugs over the valves. The cooling system should consist of a honeycomb radiator with a gear-driven fan and a water pump.

Selective type of transmission should be used with four forward speeds and reverse, with direct drive on third speed, and geared 2 to 1 on direct. The clutch should be of the cone type, fitted with cork inserts. The car should be shaft driven and should have a Timken-Detroit rear axle, roller bearings being used with it. The front axle should be of the B. & L. castor type.

The exhaust should have two complete systems of outlet, consisting of a muffler fitted with a cutout and open exhaust pipes coming through the hood. The wheels should be similar to those which Ray Harroun used in the 500-mile race and should be 40 inches in diameter, shod with 6-inch tires front and rear. There should be four large brakes on the rear wheels, two internal and two external. The wheelbase should be about 140 inches and the car should be equipped with semi-elliptic springs front and rear, and should also have Hartford shock absorbers. Steering should be of the worm and sector type, with a 20-inch wheel, hard rubber and corrugated.

The body should seat two people, seats being on the floor, with 10-inch cushions and high backs, similar to those used on the Mercer raceabout. A 50-gallon gas tank should be mounted back of the seats. I would desire a combination Klaxon horn, engine-driven tire pump, Gray & Davis dynamo, full set of Gray & Davis torpedo electric lamps and a Warner autometer. An extra tire and rim complete should be mounted in the rear of the gas tank.

The car should be built of the very best materials. Such a car as I have outlined would cost about $5,500.

OLIN M. VAN NEST.

German Valley, N. J.

Specifies Full Electric Outfit

Editor THE AUTOMOBILE:

My conception of the ideal locomotive is as here given.

The motor should have four cylinders, probably cast singly with a unit construction including motor, gearset and clutch. The suspension should be three-point and the cylinders of the T-head type. The valves should be enclosed. The motor should have a bore of 4 1-2 inches and a stroke of 5 1-2 inches. The cooling water should pass through a honeycomb radiator.

The power should be transmitted to the gearset by means of a leather-faced cone clutch equipped with spring plungers for easy engagement. The gearset should be of the four-speed and reverse type with dirct drive on third; the shafts should run on ball bearings.

The propeller shaft should not be less than 14 inches in diameter and should transmit its power to a driving axle of the same diameter. The rear axle should be braced by means of special tension and distance rods.

The frame should not measure less than 3 x 5 inches at the midship section, and there should be as near as possible one-third of the frame between the front end of the rear spring and the rear end of the front spring.

Among the accessories I would have an electric generator for lighting as well as ignition, and an electric self-starter. The dash outfit should include a gasoline gauge.

The price of this car should be $2,500.

Kingston, N. Y. EXPERIENCE.

Sizing Up the Used-Car Situation

THERE are few lines of business that the automobile public in general knows less about—but thinks it knows more about—than the second-hand car trade. The reason therefor is that every motorist, comparatively speaking, has at some time or other had an opportunity to either buy or sell a used car, or to at least witness or hear about such a transaction. A single experience of this kind will usually enable a man to form a decided opinion about the situation. But let it be said that this throws a sad light on the reasoning power of a man thinking in this fashion, for there is no more complex situation than the problem offered by the vast number of used cars that are waiting to be disposed of, nor are there many lines of trade in which a thorough acquaintance with the conditions that obtain is sc indispensable as in the second-hand car business.

It cannot be denied that this trade, if it is to be done profitably, must to a certain extent be regulated by a system. But, strange enough, the system used in this line of endeavor, however important, is an invisible one; that is, while it exists without a doubt, and while the business is carried out according to well-regulated principles, there is practically no time or work expended on any kind of filing system specially adapted to the requirements of the situation. Instead of this the ability of the men handling the work in every detail is principally relied upon in order to make the best possible out of the problem facing the dealer.

The second-hand car business has been repeatedly denounced of late by makers and agents; it has been called a nuisance and worse, and there have come about a dozen proposed solutions from various men prominent in the industry. But, considering the situation cooly and without bias, the observer will be impressed by the fact that as long as the vast production of yearly models of automobiles is continued the types out of date but still alive will have to be disposed of if their present owners are to be persuaded to buy new, and, in a good many cases, better and costlier cars. Nor is there any use in decrying any particular phase of the second-hand trade as it is now conducted, or to advocate any Utopian solutions of this problem. Here, as in so many other fields, the wisest course is rather to bear the ills we know than fly to others we wot not of.

The used car trade is handled in different styles by different men. There is hardly a firm in the metropolis which does not trade in used cars of its own make as long as these automobiles are in a salable state. In many cases this is regarded as necessary, for otherwise the prospective purchaser may buy another make of car from an agent who is more accommodating. Of course there are some makes on which such a transaction is impossible because of their low prices, but this very fact makes it improbable that a purchaser will demand his old low-priced car to be taken in and stand pat on his proposition after its unreasonableness has been explained to him.

One way of meeting the second-hand car problem consists in disposing of the used car without either a chance of winning or losing on the bargain. This idea is carried out by a number of responsible New York firms. If a prospective has become interested in the make of automobile handled by the dealer in question the salesman in charge of the transaction naturally endeavors to close the sale. In a good many cases an old car stands in the way of the new one to be bought and the following arrangement is then resorted to: The purchaser pays the vendor the full price of the new automobile, with no deduction for the value of the old car the buyer wants to dispose of. The company selling the new machine agrees, however, to do all it can to sell the used automobile for its owner, with no profit whatever accruing to the agent. In some cases the salesman doing the business may even suffer a loss because it is up to him to sell the old car for its owner; but if he should find no time to do so, and another man closes the deal in his place, he will be obliged to pay that man a commission out of his own profit on the new car sold.

Other automobile agents, when selling a new car, take in an old machine and its value is deducted from the bill made out to the customer. It stands to reason that before trading in such an automobile the agent has his experts look over the used car and value it at what it is worth. The experts in the case are men who have been specialists in the second-hand car business for many years and who know just how much it will cost to put a car in a salable state and to sell it. The value placed upon it by the expert is deducted from the bill and there is no bargaining done. After the deal has been closed the car is repaired, if this is necessary, and then sold for the price that was allowed for it to its former owner. Few firms attempt to profit on an automobile thus acquired.

The state of affairs is different, however, when used cars are handled by dealers who trade in none but used cars. Evidently these men must be still more careful in their transactions in order to do a profitable business. In their line of trade, one would imagine, the use of a suitable system must be still more indispensable than in the case of an automobile agent who handles second-hand machines but occasionally. The truth is that the true second-hand car man uses the least amount of bookkeeping of all automobile dealers. Card files, in which a special card is devoted to each car bought, and on which the details of its repair are entered afterward, are seldom used. The shrewd second-hand car man has all his system in his hand. It is a flexible system at that, thus being of the most practical kind, and its essence is: Buy as cheap as possible and sell as quick as possible for as much as you can possibly get.

If the situation, as reflected by the action of the various dealers, is surveyed, one can hardly help agreeing that the second-hand car problem is met, in practice, in the most advantageous manner possible. The majority of car owners seeking to dispose of a used car will always first try to sell the car themselves. If this scheme does not work, then it is attempted to trade in the car when buying a new one. If the owner succeeds, all the better. If, however, he does not desire to buy another machine, or if the agent makes him understand that he cannot accept the car as part payment owing to there being but little chance of his selling the machine, the owner will surely hie him to the second-hand car man's den and patiently submit to what cannot be avoided.

But the average owner distrusts every used car except the one that he has to sell. This is one more case where a man fails to see the beam in his own eye, but is very keen in noting the mote in that of his brother. This, however, influences business but little. It goes on, and the man who fails to understand the conditions and to take them into account is invariably the loser in the deal. The conditions are simply these:

A used car never looks as good as a new one; hence the desire of a man to exchange his machine for the latest model. The average owner cannot afford to throw away a good car after a year or two, hence the necessity for its being floated into the second-hand market. The production of automobiles and the demand for new ones grows steadily; at the same time a vast number of used cars have to be sold, often for a price that would buy a pretty good new car which people prefer; hence the difficulty an owner experiences in selling his used car.

Among the New Books

MONOPLANES AND BIPLANES, by Grover Cleveland Loening, B. Sc., A. M. Published by Munn & Company, of New York. 340 duodecimo pages with 278 illustrations. Price, $2.50.

THIS work on the most up-to-date subject for scientific as well as unscientific curiosity, contains a great deal of industriously collected information about the mechanical details of aeroplanes, containing descriptions and illustrations of practically all the varieties which have flown and have come under public notice. The information seems to be reliable where the work involved on the author's part is only that of the conscientious compiler. The theories which were currently accepted among aeronautic students for many years before any "heavier-than-air" machines flew, are also rendered with fidelity, and these may be of value to the reader, in so far as they serve to suggest what a large number of questions remain to be investigated experimentally before any scientific basis for orderly reasoning may be said to have been created for the guidance of either constructors or students. The inquiring reader who is satisfied to trust his intuitive perceptions will, however, find the mere mention of the various theories helpful, even if he cannot subscribe to their correctness, and herein lies probably the main value of all the books on aviation so far published. Mr. Loening's book is in this respect no exception and may perhaps be considered as especially stimulating because the author's diction and reasoning combine to rouse the reader's critical faculties. Phrases such as "data is," "enabling the lines of future development to be pointed out," "one of the greatest detriments" or "the fact that aviation is reasonably safe can unquestionably be concluded therefrom"—all plucked from the author's brief preface—can scarcely be considered as reassuring when one is looking for the earmarks of that schooled mentality whose guidance on a difficult subject should be readily accepted as of presumptive value. When we read on page 21: "That air as a medium is similar in character to water is shown conclusively by the accompanying photographic results of the experiments on stream lines of air by Marey," some doubt is aroused as to the stringency of other conclusions accepted as scientific by the author. Something more than photographs would be required to prove that air, highly elastic and compressible, is comparable in any important relations bearing upon the subject of aviation to unelastic and incompressible water; molecular mobility being about the only property which the two mediums have in common, and that in very unequal degree. Chapter V begins with this sentence: "It is well known, from the investigations of Froude and others, that the frictional resistance of a body in water was great." And this is followed by: "By analogy it would seem as if the friction of the air would also be considerable." In the face of such logic so expressed, the discriminating reader loses heart, and not even the statement that the book was contrived with assistance from members of the faculties at the Columbia University suffices for upholding the respect which its scientific verbiage would seem to claim.

An example of glib reasoning is presented on pages 19 and 20. Here we read: "In the Summer, on a dry clear day, the high temperature causes a low density"—of the atmosphere—"and the pressure is light, so that the aeroplane experiences the least resistance, and therefore at this season travels at a higher speed." It is difficult to know, of course, what an "aeroplane experiences"—to use the author's strange anthropomorphic phrase—but the careful reader of this book of instruction may safely deny the validity of the "therefore." The action of the propeller on the rarefied air as well as the sustentation such air affords are decidedly matters to be looked into before it may be asserted that the aeroplane "therefore" travels at a higher speed in thin air. And on the same page 20 a superfluous diagram sorely maligns Sir Isaac Newton's memory in ascribing to him a preposterous notion of the manner in which a horizontal stream of air acts against a vertical plane.

The author's license to teach a science which does not yet exist and a practice which has not yet become so crystallized that information for to-day holds good to-morrow, seems to have been issued on a purely commercial basis, for which it is perhaps a valid excuse, however, that those of really scientific attainments generally refuse to write anything on the subject which the public would be willing to read.

WELDING THEORY, PRACTICE, APPARATUS AND TESTS; ELECTRIC, THERMIT AND HOT-FLAME PROCESSES. By Richard N. Hart, B. S. 181 pages with 93 text illustrations. Published by McGraw-Hill Book Company, New York. Price, $2.50.

The subject of this work is theoretically in a chaotic state while in practice the arts of soldering and welding are progressing from week to week with tremendous strides. Few are in a position to keep step with the developments, and as these are intimately connected with other forms of advancement in metallurgical insight and throw highly interesting sidelights on the properties of metals, their alloys and their impurities, the technically interested public have reason to thank Mr. Hart for his courage and resolution in seizing this subject in its flight, snatching it, one might say, from out of the workshops, the testing stations and the pages of periodicals and fixing it, in so far as it will consent to be fixed, in the pages of one short volume. Nobody concerned with the joining of metals or metal parts can help receiving valuable information or hints from its pages, and even those familiar with the general conditions for the malleability and the "flow" of pure metals and alloys, with the phenomena of "solid solution," the formation, destruction and reformation of metallic crystals under the influence of heat and hammering, and with the molecular transfusion which takes places between metallic substances in many instances if only intimate contact is effected under moderate heat, will not fail to find among the facts related by the author many which will broaden or deepen their understanding for all kinds of metal work. Still the information offered is essentially practical.

In this useful work some curious lapses are nevertheless observed, as where the cohesion between two perfectly plane and smooth glass plates (in reality due to atmospheric pressure) is compared to the partial weld which may be produced between two plates of iron highly polished and heated to a dark red, or where it is stated that " the ancient Greeks knew of it (silver) as the metal electrum, an alloy of gold and silver," as if the almost pure silver of many ancient coins had been unknown to them. Such easily avoidable flaws bear witness of haste, but on the other hand the terseness of the author's diction, marred only in a few places by grammatical incongruities or clouded sense, conveys a refreshing impression of a well-filled mind capable of checking off the second-hand information which is necessarily included by comparison with a good store of data verified through personal and practical experience. On the foundation supplied in this work it should be possible in a few years to produce a thoroughly systematized textbook and shop guide on the arts of soldering, brazing, welding and fusing—now blending into one—and upon the closely related methods for cutting metal by local fusion.

MECHANICS FOR ENGINEERS. By Arthur Morley, M.Sc. Published by Longmans, Green & Co., New York. 282 pages, 200 illustrations. Cloth, $1.20.

In this work the principles of mechanics are brought to the student in a clear, concise manner which will prove valuable to those who are studying the subject without the aid of an instructor. The work is amply illustrated by diagrams which bring out the points involved in a manner which renders them easily understood by the students of elementary mechanics as applied to engineering.

Kinematics, the study of bodies in motion, and statics, the study of bodies at rest, are taken up in the first part of the book, while the remainder is devoted to the laws of inertia and gravity, the moment of inertia and the elements of graphic statics. Relative examples and their solutions are given as well as examples for solution by the reader.

Harking Back a Decade

ITEMS appearing in *The Motor Review* of November 14, 1901:

An injunction has been issued by the United States Circuit Court in New York, restraining Frederick R. Wood & Son, makers of electric vehicles, from the use of the two-motor drive construction patented by the Electric Vehicle Company.

The Milwaukee Automobile Club has been planned and as soon as it is formed it will affiliate with the Automobile Club of America. Tours, social and sporting events will be arranged.

The recent tests in handling mail at Syracuse showed that the automobile could effect a saving of 66 per cent. in the time involved in collecting.

Actual sales at the Madison Square Garden show just closed totaled close to the $1,000,000 mark. The demonstration track around the exhibits was abandoned this year, but most of the exhibitors had demonstrating cars outside the building to give street rides to those who really meant business. The attendance was very steady throughout the show but at no time approached what would be considered a crowd.

The Franklin company, which has been experimenting with a four-cylinder, air-cooled motor which drives direct to the rear axle in high gear and with two forward speeds and reverse, is about to market its experiment. Four pedals control the brake, reverse, high and low speeds. The car has 28-inch wheels and weighs 850 pounds. It is rated at 7 horsepower.

The Diamond Rubber Company, of Akron, O., is erecting an addition to its plant that will increase its floor space to 500,000 square feet. The factory is one of the largest of the kind in the United States.

The Winton Motor Carriage Company will establish branch houses in Philadelphia, Boston and Chicago as the result of its increased capitalization. This move will be made next Spring.

The automobiles shown at Madison Square Garden one year ago were as a class shaftless carriages, a combination of the regular American carriage and a motor. The vehicles shown this year are very largely of the French type, which, to all appearances is rapidly winning favor with American owners, not as a foreign fad but on its technical merits and the appropriateness of the design to the required service as a pleasure locomotive.—Editorial.

The automobile world here is now goaded anigh to the revolutionizing point, and something must be done. The worst of it is that there no sort of appeal against the sentences of these bundles of crassly and conservatively prejudiced old women, and though the Lord Chancellor is believed to possess some power over them, I can recall no publicly known incident in which that power has been put into force.—London correspondence on conviction of automobilists for alleged speeding.

Fifty cars of the new model Stevens-Duryea car are under construction at the Chicopee Falls factory. Three of the test cars have been in use since last Summer with satisfactory results. The car has a two-cylinder motor, rated at 5-horsepower and is equipped with wire wheels.

W. J. Stewart, of Newark, N. J., driving a Locomobile, claims the long-distance speed record on a hill as the result of his climb of Eagle Rock near Orange. This hill averages 18 per cent. grade. Mr. Stewart's car made the climb in 2:43. The length of the hill is not given.

Eleven manufacturers of automobiles and eight accessory houses have already made application for blocks of space exceeding 1,000 square feet each at the Chicago Automobile Show, which will be held in the Coliseum March 1-8. All the available space has been snapped up and indications point to a show of far greater magnitude than the one of last season.

English "Driver" Ousts French "Chauffeur"

French motorists are up in arms owing to the fact that an English word has slipped into the French vocabulary and is becoming quite popular. Reference is made to the word "driver," which, to a degree, has supplanted the word "chauffeur." But it is a question whether those who have adopted it will abandon it. The same sort of protest was heard when the proposition was first made to change the road right-of-way from right to left, the latter being the English system. But the French people managed to survive the shock and "driver" will doubtless replace "chauffeur."

Calendar of Coming Events

Shows

Nov. 20-25 .... Indianapolis, Ind., Fall Show, Indianapolis Automobile Trade Association.
Dec. 30-Jan. 6 ...... Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.
Jan. 2-11 .... New York City, Hotel Astor, Importers' Salon.
Jan. 6-13 .... New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20 .... New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17 .... New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 13-27 .... Philadelphia, Annual Show, First and Third Regiment Armories, Philadelphia Automobile Trade Association.
Jan. 15-20 .... New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 13-19 .... Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 22-27 .... Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dealers' Association.
Jan. 22-27 .... Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 27-Feb. 10 .... Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 29-Feb. 3 ...... Scranton, Pa., 13th Regiment Armory, Second Annual Show.
Feb. 3-10 .... Montreal, Canada, National Show, Drill Hall, Automobile Club of Canada.
Feb. 5-17 .... St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17 .... Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 14-17 .... Grand Rapids, Mich., Third Annual Show.
Feb. 17-24 .... Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24 .... Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Feb. 17-24 .... Pittsburg, Pa., Second Annual Show, Exposition Bldg., Pittsburg Auto Show Association, Inc.
Feb. 19-24 .... Omaha, Neb., Seventh Annual Show, Auditorium, Omaha Automobile Show Association.
Feb. 19-24 .... Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 20-24 .... Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Week Feb. 22 ...... Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
Feb. 26-Mar. 2 ..... Elmira, N. Y., Second Annual Show, Elmira Automobile Club.
March 2-9 .... Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.
March 4-9 .... Denver, Col., Auditorium, Annual Show.

Meetings, Etc.

Nov. 20-24 .... Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 22 .... Road Users' Day, under direction of Touring Club of America.
Dec. 20 .... New York City, Waldorf-Astoria, Annual Banquet of the Automobile Club of America.
Jan. 18-20 .... New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Nov. 27 .... Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30 .... Los Angeles, Cal., Track Races, Motordrome.
Nov. 30 .... Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25-26 .... Los Angeles, Cal., Track Races, Motordrome.

A Foreign Solution

A FEW years ago when a car maker wanted more power he added to the cylinder bore and stroke; in some cases he added another pair of cylinders, converting the four-cylinder chassis into a six. Often when adding extra cylinder power more weight was added, heavier parts were deemed necessary to care for the additional power, and little thought was given to the matter of reducing the weight of the parts by the adoption of higher grades of steel. In those days if more power was wanted the only solution was more cylinder capacity. This system is changing very rapidly in America, and it has changed wonderfully in Europe. In America the demand for higher efficiency with reduced fuel and other expenses has not been so great as abroad. In England, where there is a tax on gasoline per gallon as well as a registration tax by horsepower, and where many of the buyers have a limited income on which to live and to operate the car, it is necessary for a car maker to practically guarantee the fuel consumption of his machine, to guarantee the hill-climbing ability, to guarantee the speed on level roads and to guarantee the probable tire mileage.

It has been necessary with the English builder, and with a great many French builders also, to give higher motor efficiency with reduced cylinder capacity and with a lower fuel consumption. This has caused the engineering departments to go to work. The result has been that they are using the long stroke abroad because it is more economical on fuel and gives more power proportionately than the shorter stroke variety. In America several of the makers who are to-day experimenting with the long-stroke types say they consume more gasoline than the square motor. It is quite natural that with experimental engines, as many of them are, the fuel economy factor should not be anywhere near the low-level mark. It will take a year or so before consumption is cut down to the minimum. Not only has the foreigner cut down fuel consumption, but he has increased the power.

The long-stroke motor has brought many problems along with it. One has been the reduction in the weight of reciprocating parts, meaning pistons, connecting-rods and wristpins. It is now customary in standard touring cars to fill the pistons below the wristpins with small holes varying in diameter from 1 to 2 inches. These perforations reduce weight very much. Other makers, instead of doing this perforation job, have adopted steel pistons. These steel pistons are stampings. They are very light and are very cheap to make. A little weight has been cut off the wristpins by making them of larger diameter and hollow. The connecting-rod weight has been very materially reduced in many ways. One maker uses a hollow rod. It is expensive, but strong, and the reduced weight gives a smoother running motor. The piston, wristpin and connecting-rod unit has to be stopped and started twice in every revolution of the crankshaft, and when a crankshaft is revolving 1500 revolutions per minute it means 3000 stoppings and 3000 startings of this weight in every minute of time. It takes power to start this weight in movement and increase it to a high speed, and it also takes power to stop it. The heavier these parts are the more power is consumed in this starting and stopping process.

It may be that some car users will say that with lighter reciprocating parts there will be more rocking or pivoting of the pistons and consequently more piston slap and motor noises. This might be true had the designer not anticipated the difficulty, but he has mastered the situation by adding to the length of the piston, so that with the reduced weight and increased length there is a steadier piston than formerly and there is a motor with less piston slap, and consequently less noise.

Much talk is indulged in as to what constitutes a long-stroke motor. Some American car builders advertise long-stroke motors when the bore is 4 inches and the stroke 4.5 inches. Such is not a long-stroke motor. The long-stroke motor should have the stroke at least from 25 to 40 per cent. in excess of the bore. Of the new models brought out in France and England this year the stroke-bore ratio averages 1.5 to 1. There are a few new motors with the stroke a good deal more than half as great again as the bore. There are two or three in which the stroke is double the bore, and one of the more progressive ones has the stroke-bore ratio at 2.75 to 1. Two years ago such constructions were considered racing monstrosities, but to-day it is different. The makers have refined on the racing creations of the past; some are marketing them as the regular product.

The American builder will find that manufacturing a long-stroke motor is not merely adding a few inches to the stroke and cutting off a fraction of an inch or perhaps an inch from the bore. The long-stroke motor is a new design. It is a new conception of a motor and not a working over of an old design. When the stroke-bore proportion is changed the lubrication problem is changed, the valve design problem has been altered, the carburetion work changed, and, in fact, the entire motor situation is altered. The long-stroke motor must be designed from the ground up. It is just about as sensible to make a long-stroke motor out of a square one, in the hope of getting a fair measure of success, as it is to take a touring car chassis and, by changing the gear ratio, transform it into a truck chassis.

Census Figures on the Industry

WASHINGTON, D. C., Nov. 13—A further preliminary statement of the general results of the thirteenth census of establishments engaged in the manufacture of automobiles, including bodies and parts, was issued to-day by Census Director Durand. It contains summaries which give the general figures, the number and value of machines by kind, for 1904 and 1909, and the horsepower rating by classes for 1909. The report was prepared under the direction of William M. Stewart, chief statistician for manufactures, Bureau of the Census. The figures are subject to such revision as may be necessary after a further examination of the original report.

The summary shows increases in all the items at the census of 1909 as compared with that for 1904.

The number of establishments increased 317 per cent.; capital invested, 653 per cent.; the gross value of products, 730 per cent.; cost of materials, 901 per cent.; value added by manufacture, 596 per cent.; average number of wage earners employed during the year, 528 per cent.; amount paid for wages, 580 per cent.; number of salaried officials and clerks, 682 per cent.; amount paid in salaries, 654 per cent.; miscellaneous expenses, 389 per cent.; primary horsepower, 647 per cent.

There were 743 establishments in 1909 and 178 in 1904, an increase of 317 per cent.

The capital invested as reported in 1909 was $173,837,000, a gain of $150,753,000, or 653 per cent., over $23,084,000 in 1904. The average capital per establishment was approximately $234,000 in 1909 and $130,000 in 1904.

The value of products was $249,202,000 in 1909 and $30,034,000 in 1904, an increase of $219,168,000, or 730 per cent. The average per establishment was approximately $335,000 in 1909 and $169,000 in 1904.

Weed Chains Win Another Battle

Another victory for the Weed Chain Tire Grip Company and the Parsons Non-Skid Company, upon the patents on which the former bases its product, was scored in the United States Circuit Court for the Southern District of New York, when Judge Lacomb signed an interlocutory decree affirming the right of the complainants in the patent and issuing a permanent injunction against E. J. Willis Company, of Boston, and waiving the prohibition so as to cover the Whitaker Chain Tread Company also.

The decree appoints Commissioner Shields to take testimony for an accounting between the parties and when that is done the decree may be made final. In the meantime the respondents have the right to appeal the case to the Circuit Court of Appeals, which will probably be done.

The Weed chain makers are in the midst of an extended battle to assert their rights under the Parsons patents and at this time there are still pending 175 suits against various alleged infringers of those patents. In this number of cases preliminary injunctions have been granted while several final decrees have been entered against individual infringers.

The amount of money involved in the present litigation is considerable but it has not been definitely determined and will not be until Commissioner Shields has finished hearing the testimony.

The interlocutory decree connects the Whitaker company with the respondent in this language:

"The E. J. Willis Company without right or license from the complainants making, selling and using chain grips known as the Whitaker Chain Grip made by the Whitaker Chain Tread Company, which has conducted the case of the respondent."

Frederick S. Duncan conducted the case for the complainants.

The patent under consideration is No. 723,299, granted August 24, 1903.

Government Investigates Naphthalene

WASHINGTON, D. C., Nov. 13—As a large part of the road work in this country seems destined to be effected by the use of tars in road treatment and construction, a systematic investigation of the effect of various constituents upon the adaptability of tars as road binders is now being made by the Good Roads Division of the Department of Agriculture. While definite conclusions are not announced, the results strongly indicate four determined facts, as follows:

That the fluxing value of naphthalene for tar pitches is somewhat greater, although quite similar, to the heavier naphthalene-free tar distillates, until the mixture becomes saturated with naphthalene.

That for the harder tar pitches the addition of very small percentages of naphthalene will produce a marked increase in fluidity of the resulting product.

That for the softer pitches the addition of naphthalene in small quantities causes less increase in fluidity than for the harder pitches.

Fifty-four in Savannah Road Races

Extending the time for closing entries to the Savannah road races until November 23 was decided upon yesterday in order to allow several belated entries to reach the authorities.

The list now contains fifty-four cars, divided among the four races as follows: Grand Prize—Benz (3), Fiat (3), Abbott-Detroit (2), Lozier (2), Marmon (2), Mercedes (2), Buick (2), Inter-State (2), Apperson, Ford and Pope-Hummer. Total, 21.

Vanderbilt Cup—Fiat (3), Lozier (2), Mercedes (2), Abbott-Detroit (2), Inter-State (2), Mercer (2), Marmon (2), Opel, Jackson and Ford. Total, 18.

Savannah Challenge Cup—Marmon (3), Mercer (3), Case (2), Ohio and Cino. Total, 10.

Tiedeman Trophy—E-M-F (3), Abbott-Detroit (2). Total, 5.

The course was thrown open for preliminary practice on Monday, and the circuit, which has been reduced to 17.14 miles has been pronounced faster than before by 5 miles an hour.

According to the officials there is a possibility of getting in ten more entries.

James M. Carples, of the New York Mercedes branch house, stated yesterday that the Mercedes entries in the Grand Prize are conditioned upon the showing of the cars in the Vanderbilt Cup race.

The New York official party, consisting of R. L. Morrell, referee, and his associates, left this morning for Savannah.

Knight Says Argyll Infringes

Cable advices from Coventry, England, declare that Charles Y. Knight has filed suit on behalf of his company against the Argylls, Limited, makers of the Argyll automobile. The complaint alleges infringement of the Knight patent covering the sleeve-valve motor in all its details. The new Argyll is equipped with a single-sleeve device which is given a reciprocating motion, while the original Knight engine has two concentric sleeves. In the Argyll the rotary valve principle is also combined with the reciprocation of the sleeve.

News of Shows—National and Local

THERE was a little more activity to be noted in the locai show situation during the past week than there has been for a month back. The decorative plans are being discussed, and while everything in this line is still tentative at best, the main ideas under consideration embrace the simplest plan of decoration ever used for an automobile show in the preparations of the National Association of Automobile Manufacturers for its display at the Grand Central Palace.

It would be painting the lily to go into any extensive decorations in such a show hall, as the architectural features of the building are so handsome without decoration that something would be detracted from their appearance by the copious use of bunting and lights.

The plan is to install panels over the windows, painted to represent autumn scenes, and to confine the other decorations to vines, greenery and potted plants.

At Madison Square Garden the scheme this year is still indefinite. Several ideas of decorations are under consideration. One of the favorites is an Egyptian theme, which calls for conventional effects and vivid colors.

Complete lists of the exhibitors at both shows are being prepared and will be issued as soon as possible.

The space allotments at the Palace have been revised several times, the latest change being made necessary by the withdrawal of the Colby & Babcock electric.

So far about forty members of the motor and accessory manufacturers and twenty-five independent makers have taken space in the accessory show, which will be held on the third floor.

All the space for the first week at Madison Square Garden has been taken.

Milwaukee Show Will Fill Auditorium

MILWAUKEE, Nov. 13—The entire Milwaukee Auditorium, affording more than 65,750 square feet of floor space, will be required to house the 1912 motor show of the Milwaukee Automobile Dealers' Association, which will be held from Jan. 13 to 19 inclusive. The main arena, which has heretofore sufficed to contain all pleasure car exhibits, will be supplemented by the arena basement, and the commercial vehicles will be placed in other large halls of the basement. The four smaller halls on the main floor will be used for accessory and parts displays. Bart J. Ruddle, 71 Sentinel building, Milwaukee, is manager.

Omaha Show February 19-24

OMAHA, NEB., Nov. 13—At a second meeting of the directors of the Omaha Automobile Show Association, it was decided to hold the Omaha show from Feb. 19 to 24.

It was decided to hold the show at the auditorium again as it is more centrally located than the Coliseum. But as the auditorium has been too small for the show for the last two or three years, it is planned to build a temporary annex on a vacant space to the south of the building, for the commercial vehicles. This will leave the main floor of the auditorium for pleasure cars.

As there have been thirty-three firms represented in this association, and twelve more are applying for admission, the 1912 show will be by far the largest ever given here.

Cincinnati Exhibit in Music Hall

CINCINNATI, O., Nov. 13—The Cincinnati Automobile Dealers' Association has definitely decided to hold the association's annual show in the north wing of Music Hall, this city, during the week of February 19 to February 24, for pleasure vehicles only and a separate exhibit for commercial vehicles during the first three days of the following week.

The committee chairman were appointed as follows:

Chairman of all committees, Edward F. Herschede; display, space, tickets, badges and program, Robert T. Crowthers; publicity campaign. E. A. Kruse; decorations, H. S. Leyman; halls and grounds, Frank H. Miller; heating and lighting, W. G. Welbon; concessions, George Behlen.

Show Dates for Providence

PROVIDENCE, R. I., Nov. 13—Dates for the Providence automobile show have been set for January 22-27. The State Armory will be the stage, and passenger and freight cars as well as accessories will be displayed. The floor space of the main hall is 38,000 square feet. The rules as framed are much the same as those in force at all the important exhibitions of automobiles. Arthur S. Lee will manage the show.

Pittsburg Leases Exposition Building

PITTSBURGH, PA., Nov. 13—The Pittsburgh Auto Show Association, incorporated, has leased Exposition building for their second annual automobile show from February 17 to 24, 1912.

The association held its annual election and elected the following officers and directors: E. A. Williams, president; Elias Lange, vice-president; Albert A. Buhl, secretary; Julian B. Howe, treasurer; J. H. McClarren, B. F. Benson, E. E. Gregg, James D. White and L. G. Martin.

As the association will have twice as many members to show as last year, it was found necessary to provide additional space at the Exposition so that all could properly show their cars and trucks. By going to quite an expense, it was found feasible to remove some of the permanent booths and thus provide extra room.

Thomas I. Cochran, who managed the Exposition automobile show for the association last year, has been retained as manager this season. Offices have been leased and fitted up in the Highland building.

Fifty-two makes of pleasure cars and 16 of the highest grades of trucks are handled by the members of this association. The automobiles and trucks will be shown on the same floor in separate aisles. The balcony is large enough to accommodate all the accessory dealers of this section.

The Exposition building is larger than Madison Square garden in New York; in fact, is the largest building used for show purposes in the United States. There is not a pillar or post in the entire building to obstruct the view or interfere with an exhibit.

Scranton Gets Ready for Show

SCRANTON, PA., Nov. 13—The Scranton Annual Automobile Show will be held in the 13th Regiment Armory from Monday. January 29, to Saturday, February 3, 1912, as the former show was cramped for room in the Town Hall. The 13th Regiment Armory, one of the best in the State, has been secured for the present show. Forty thousand square feet of floor space will be used, and nearly all this space has been taken. About 100 automobiles, and a large line of accessories, will be exhibited. Hugh B. Andrews, who so successfully managed the initial show here. will manage this year's exhibition.

How Chicagoans Will Sell Used Cars

CHICAGO, Nov. 13—Having worked on the problem for a month, the Chicago Automobile Trade Association to-day, at a general meeting of the association, adopted the report of the special committee appointed to look into the second-hand car proposition, which report had previously been carefully considered from various angles and then favorably acted upon by the directors.

The Chicago idea is different from those in vogue in other cities in that it does not attempt to bind the dealers by iron clad contracts—it simply furnishes a source of information which will be of value to the tradesmen in setting prices on old cars offered as part payment on new ones. The scheme as outlined is as follows:

First—There shall be established a bureau of information to be conducted under the direction of the directors of the association.

Second—The association shall have prepared blank forms arranged to receive a list of all models made by any one manufacturer for the year 1908, and each subsequent year, including model, number of passengers, type of motor, selling price when new, allowance price for each model in average condition, and resale price when thoroughly overhauled.

Third—These blanks forms shall be distributed to all dealers, and each dealer shall file such forms, properly filled out, giving the above information, with the secretary of the association.

Fourth—Thereafter on the first of every month each dealer shall file with the secretary a revised card showing any changes in prices or models.

Fifth—The association shall have copies of each report or revised report printed in quantity sufficient to furnish one or more to each member of the association; suitable loose leaf binder covers shall also be obtained, marked on the outside with the name of the association, in which a copy of each report shall be placed alphabetically arranged; a copy of these reports so bound shall be furnished by the association to each of its members.

Sixth—The association shall furnish each member with a printed copy of each revised report thereafter filed with it by any dealer; and for this purpose the association shall employ a messenger whose duty it shall be to deliver these revised reports to each member, personally placing the new sheets in each binder, and returning the old sheets to the secretary of the association.

Seventh—These binders shall be the property of the association at all times, and shall be renewed by it whenever necessary.

Eighth—A committee of three members of the association shall be appointed by the president each year immediately after the election of officers.

Ninth—It shall be the duty of this committee, whenever any member fails to file the reports provided for by these rules, to obtain, by any means that they may consider appropriate, sufficient information to enable them to prepare and file with the secretary a report similar to a dealer's report, which shall be received in lieu of the report of the particular dealer.

Tenth—Whenever any member shall sell a second-hand car, such member shall immediately report by mail to the association, filling for that purpose a blank form, to be furnished by the association, which shall read as follows:
"I, today sold..............second-hand car model.......... number of passengers............ price when new.............. for $........... Signed........................... Dated............................"

Eleventh—The association shall have compiled weekly a list of all sales of second-hand cars reported each week, model and price, and a printed copy of this list shall be mailed to each member; the names of the dealers selling the cars shall not be made public, but kept on file by the association for its records.

Twelfth—The association shall also obtain information from all possible sources to enable it to print weekly a list of the number of the various models and makes of second-hand cars on sale in the hands of members. A copy of such lists shall be mailed to each member.

Thirteenth—Each member of the association shall render all possible assistance to the association in obtaining this information and shall furnish it with complete lists of all cars on hand for sale.

Fourteenth—Each member after completing a trade for any second-hand car shall immediately report by mail to the association, filling in a blank form, to be furnished by the association, which shall read as follows: "I, today, took a second-hand car, model.......... allowing $.......... as part payment on a new car. Signed........ Dated........."

Fifteenth—Each member shall make all quotations on second-hand cars to their customers in writing, and shall mail a copy of such quotation, omitting the name of the customer, to the association upon forms to be supplied by the association.

Sixteenth—The association, through its secretary, shall furnish to any of its members, on request, the amount that any dealer has allowed for any second-hand car or any quotation made by any dealer to a prospective customer on any second-hand car, using for this purpose the information obtained from the reports provided for in clauses 14 and 15.

Seventeenth—The expense of obtaining and furnishing the information provided for in the preceding clauses 1-15, shall be divided pro rata among the members of the association dealers in motor cars.

Pullman Owners Tour to Factory

YORK, PA., Nov. 13—The first sociability run of the Pullman Automobile Company, Philadelphia, was held to-day from the Quaker City to York, and fifteen Pullman cars were entered by owners from Philadelphia and Reading.

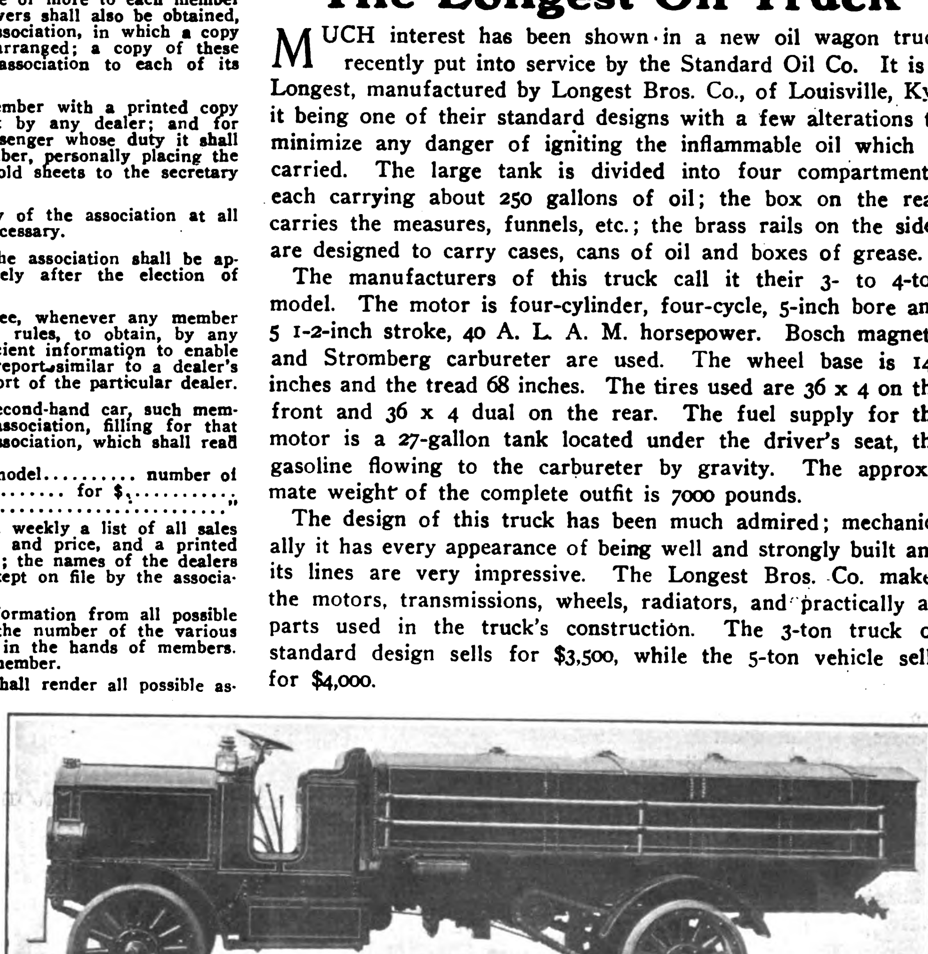
W. L. Garland, driving a 1911 Model K Pullman, won the run. His time for 89 miles was 5:03.30. The time for the run had been fixed at 4 hours, 56 minutes and 10 seconds. Mrs. W. G. Preston, Philadelphia, won the ladies' prize for guessing closest to the elapsed running time. Her guess was 4 hours and 56 minutes. I. S. Cohen, of the Philadelphia Taxicab Company, came within 30 seconds of winning the first prize, he making the distance in 5 hours and 4 minutes. The route was via Paoli, Coatesville, Lancaster, Columbia and York.

The Longest Oil Truck

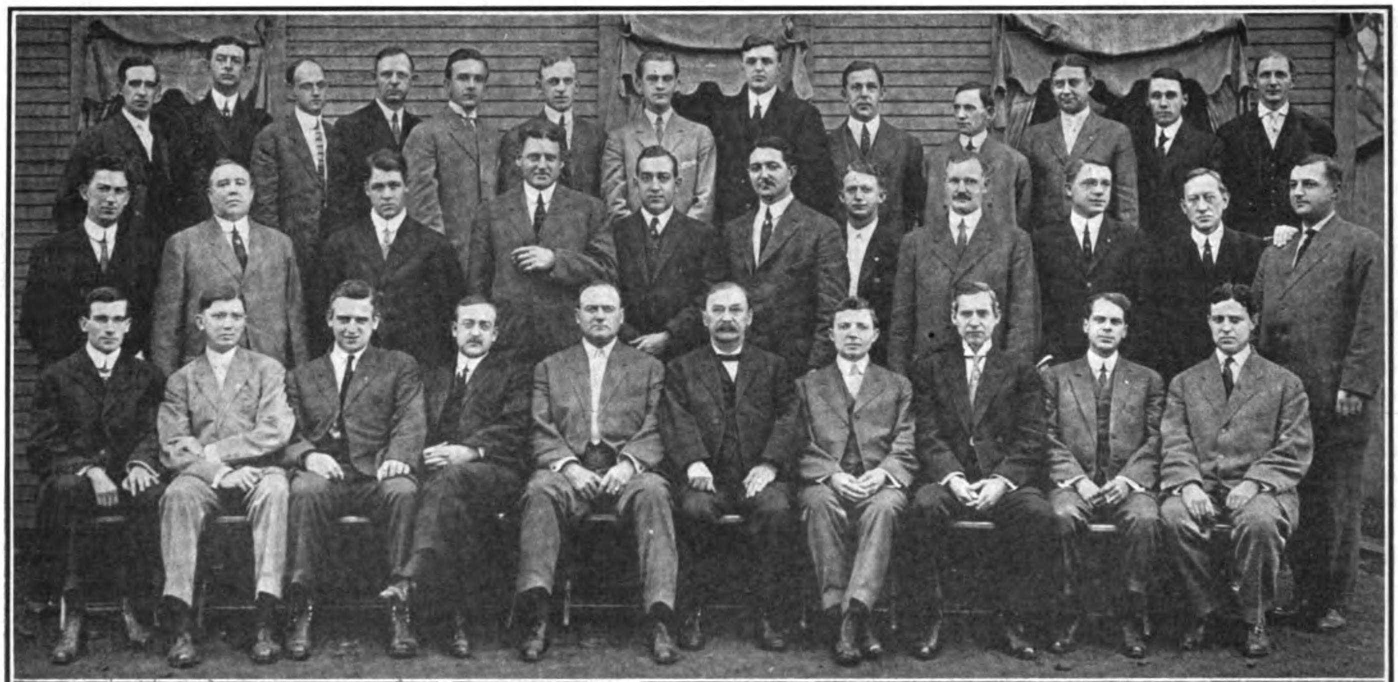
MUCH interest has been shown in a new oil wagon truck recently put into service by the Standard Oil Co. It is a Longest, manufactured by Longest Bros. Co., of Louisville, Ky., it being one of their standard designs with a few alterations to minimize any danger of igniting the inflammable oil which is carried. The large tank is divided into four compartments, each carrying about 250 gallons of oil; the box on the rear carries the measures, funnels, etc.; the brass rails on the sides are designed to carry cases, cans of oil and boxes of grease.

The manufacturers of this truck call it their 3- to 4-ton model. The motor is four-cylinder, four-cycle, 5-inch bore and 5 1-2-inch stroke, 40 A. L. A. M. horsepower. Bosch magneto and Stromberg carbureter are used. The wheel base is 144 inches and the tread 68 inches. The tires used are 36 x 4 on the front and 36 x 4 dual on the rear. The fuel supply for the motor is a 27-gallon tank located under the driver's seat, the gasoline flowing to the carbureter by gravity. The approximate weight of the complete outfit is 7000 pounds.

The design of this truck has been much admired; mechanically it has every appearance of being well and strongly built and its lines are very impressive. The Longest Bros. Co. makes the motors, transmissions, wheels, radiators, and practically all parts used in the truck's construction. The 3-ton truck of standard design sells for $3,500, while the 5-ton vehicle sells for $4,000.



New oil truck built by the Longest Bros. Co., of Louisville, Ky.



News of the Week Condensed

CONVENTION OF SWINEHART SALESMEN AND BRANCH MANAGERS AT THE GENERAL OFFICES AT AKRON, O.

Top Row, left to right—A. T. Barder, Chas. J. Parker, W. K. Gardner, J. F. Lemmon, G. L. Moore, F. C. Grant, E. Flagg, Jr.; C. A. Swinehart, J. G. Boss, W. E. Boyle, W. J. Kreuder, H. L. Houk, G. A. Wait, E. O. Hoopenganer, J. J. Thompkins, A. J. Green, W. W. Wuchter, R. A. May, C. O. Baughman, C. W. Harris, S. G. Andrews, F. H. Burgher

ST. LOUIS, MO.—Local dealers are in a controversy with the Secretary of State in regard to the legality of the practice of issuing pasteboard duplicates of the dealer's license to purchasers of new cars, for use until the State license has been obtained. The Secretary of State recently announced that any motorist using a pasteboard tag would be subject to arrest and fine. The dealers declare their intention of testing the question in the courts, if necessary.

NEWARK, N. J.—An automobile repair plant will be erected here by Eisele & King.

BOSTON, MASS.—W. V. Bennett is the latest addition to the salesforce of the local Grout branch.

LIMA, O.—The A. D. Maus Auto Company of 114 East Elm street has taken the agency for the 1912 Mitchell.

WASHINGTON, D. C.—The C. B. McAllister Company has secured the Ford agency for Washington county.

AKRON, O.—The Swinehart Tire & Rubber Company of this city will erect a new building next to its present plant.

ST. LOUIS, MO.—Announcement is made that the Mound City Buggy Company is to handle the Jackson in this vicinity.

LEIPSIC, O.—The American Foundry Company of this city has changed its name to the Temco Electric Motor Company.

KANSAS CITY, MO.—The Auburn Motor Car Company has removed to the corner of Sixteenth street and Grant avenue.

BUFFALO, N. Y.—The Thomas Motor Car Company, of this city, has increased its capital stock from $50,000 to $100,000.

NEW YORK CITY—The Poertner Motor Company has taken the agency for the Herreshoff line of small cars for this district.

WILMINGTON, DEL.—The Auto Sales Company, a local concern, has begun the manufacture of a motor truck of its own design.

ST. LOUIS, MO.—The Kisselkar branch, of which George Dunville is manager, has taken new quarters at 3008 South Grand avenue.

SAN FRANCISCO, CAL.—W. A. Baker of Seattle, Wash., has joined the forces of Don Lee, the local distributor of the Cadillac.

PITTSBURGH, PA.—The Ohio Motor Car Company of Elmwood - Cincinnati has named the Federal Motor Company as local agent.

RICE LAKE, WIS.—The Automobile Trip Carrier Company will build a 50 x 120-foot brick addition to its factory at once, near the foundry building.

BOSTON, MASS.—The R. L. and H. H. Smith Company, distributor of the Selden cars and the Mais truck, intends to establish a service department.

MONTREAL, CAN.—Scott and Pease have opened a showroom at 632 Saint Catherine street, West. They are agents for the Baker Electric and for the Pope-Hartford.

GRAND RAPIDS, MICH.—The Silverman automobile factory to be built in this city will be two stories high, with basement, and will measure 59 by 100 feet. It will cost $10,000.

MUSCATINE, IA.—Bowman Brothers have enlarged their garage and salesroom on Front street and have contracted with the Buick company for their line for 1912 for Muscatine and Louisa counties.

ROANOKE, VA.—The Virginia Motor Car Company is having plans prepared for the erection of a fireproof garage, 50 by 154 feet. The building will be equipped with a turntable and electric elevator.

MANSFIELD, O.—C. H. Voegele has taken the agency for the Velie car for this vicinity. He is building a large garage for the purpose of handling Velie freight automobiles as well as pleasure vehicles.

WASHINGTON, D. C.—R. C. McDowell, of Miller Brothers' automobile supply house, has been appointed superintendent of the garage on Church Street owned by the firm.

ALEXANDRIA, VA.—The B. F. Board Motor Truck Company is planning to erect an addition which will increase the capacity of the plant from 200 to 400 trucks a year.

ST. PAUL, MINN.—According to records in the office of the Secretary of State, there are 19,206 automobiles in use in Minnesota. They are valued at approximately $2,000,000.

GALESBURG, ILL.—The firm of Hobbie and Martin has passed into the hands of W. P. Martin who will continue to carry on the business under the name of the Central Garage.

SYRACUSE, N. Y.—The Chase Motor Truck Company, of this city, expects to begin operations in the new 3-story factory addition on Wyoming street about the end of next month.

BOSTON, MASS.—The Hollander Motor Car Company, agent for the Metz car in New England, has moved into its new building on Boylston Street, near Massachusetts avenue.

KANSAS CITY, MO.—The local branch distributing house and service station of the Remy Electric Company has been moved from 416 East Fifteenth street to 509 East Fifteenth street.

SAN FRANCISCO, CAL.—J. D. Anderson, general sales manager of the United States Tire Company, is inspecting the branches which the company has opened on the Pacific Coast during the past few months.

NEW YORK CITY.—American-made tires to the value of $1,715,322 were exported during the first eight months of this year. In August the exports of tires were $251,262, a gain of over $100,000 over August, 1910.

CINCINNATI, O.—Charles C. Craig, formerly connected with the Chicago branch of the Haynes Automobile Company, has assumed the position of sales manager for the Enger Motor Car Company of this city.

KANSAS CITY, MO.—Christian & Company, formerly agents for the Hupmobile and Hupp-Yeats Electric, have been succeeded by the Hupmobile Sales Company of Kansas City. C. C. Christian is manager.

CHICAGO, ILL.—Charles V. Severin, who has been connected with the automobile industry for the past 7 years, has been placed in charge of the service department of the local branch of the Velie Motor Car Company.

CLEVELAND, O.—The F. B. Stearns Company, of this city, has rented the factory of the Royal Tourist Motor Car Company, E. 72nd street and St. Clair avenue N. E., which in future is to be operated as Stearns plant No. 3.

CHICAGO, ILL.—The Lininger Implement Company of Omaha, Neb., will represent the Lincoln Motor Car Works of this city throughout Nebraska and Wyoming. It will act as distributor for the Lincoln light delivery wagon.

AKRON, O.—The Goodyear Tire & Rubber Company of this city will occupy the last of its series of new buildings in three weeks. The latest addition is to be occupied by stock and the shipping department of the company.

NEW YORK CITY—Melvin J. Adams, formerly of the United States Motor Company, has joined the advertising department of the American Locomotive Company. Mr. Adams will assist in the preparation of the Alco literature.

SYRACUSE, N. Y.—A. D. McLachlan, formerly connected with the Royal Tourist Motor Car Company, of Cleveland, O., has resigned and has accepted the position of general sales manager with the Sangford-Herbert Company, of this city.

KENT, O.—The prospects for the building of a new automobile works in the city are very favorable. As soon as enough of the lots have been paid for to warrant building, the Criterion Motor Car Company of Pittsburgh, will erect its factory.

INDIANAPOLIS, IND.—The International Metal Polish Company of this city has broken ground for a new factory. The new building will be of brick, with inside construction of reinforced concrete.

WILMINGTON, DEL.—Elaborate preparations have been made by the Delaware Automobile Association for its annual banquet, which will be held Friday evening at the Clayton House. Covers will be laid for 200 persons.

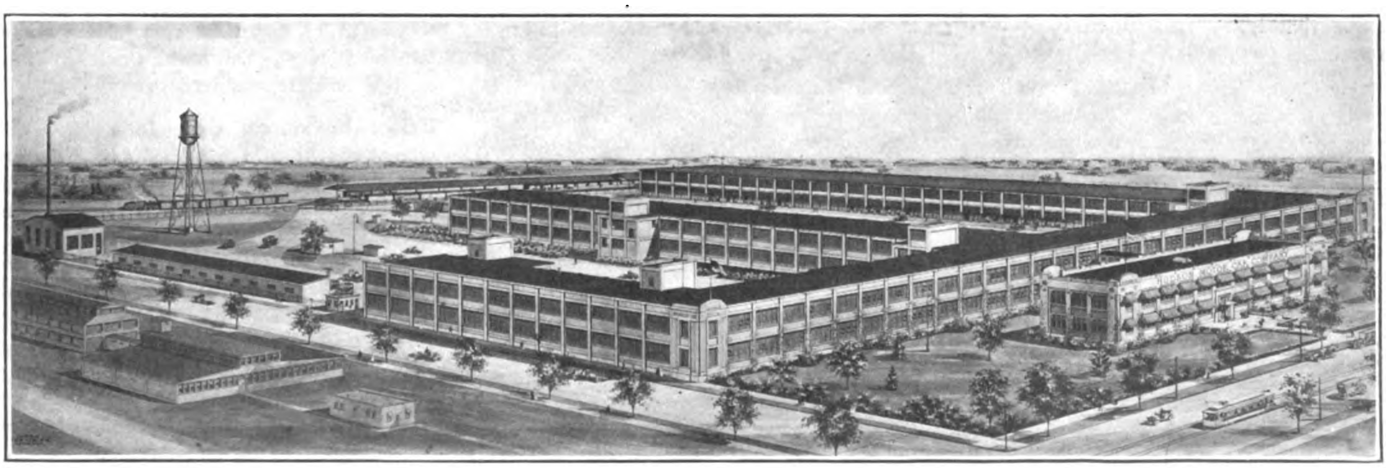
PORTLAND, ORE.—S. C. Houston, associated with the sales force of the White Motor Car Company, has been duly installed as manager, succeeding C. A. Eastman, who will now head the sales force and devote his entire attention to the selling of cars.

CINCINNATI, O.—The Fisher Motor Car Company, successor to the Speedwell Motor Car Company of this city, has leased the modern garage and salesrooms located at 804-808 Sycamore street for 6 years. The lessee is a representative of the Speedwell car.

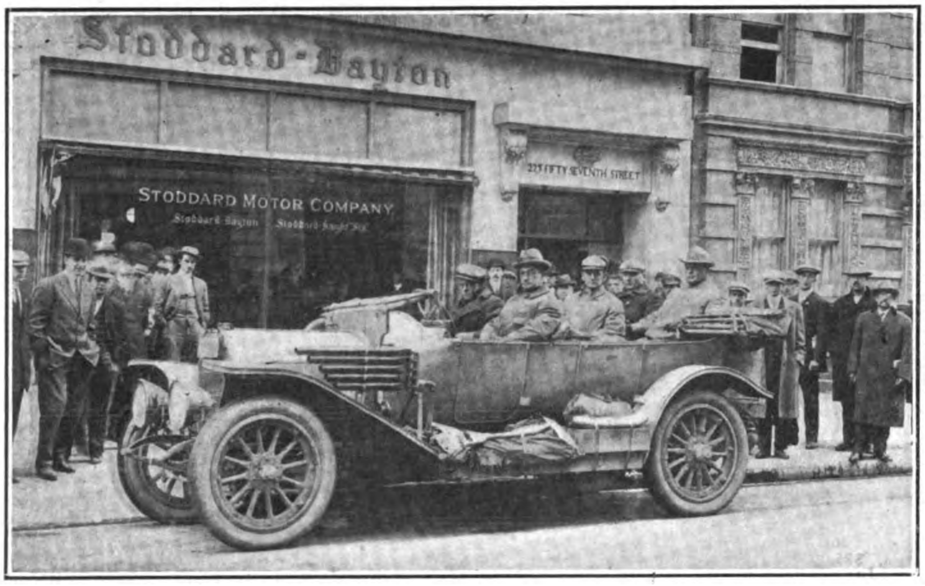
CLEVELAND, O.—Upon the application of the Panama Rubber & Supply Company, the Columbia Refining Company, the Cleveland Auto Top & Trimming Company, and the M. & M. Company, A. J. Schur has been named receiver for the Kissel Kar Company, of this city.

INDIANAPOLIS, IND.—The commissioners of Washington county, Ind., have purchased that part of the toll road running through the county. The road, which has been operated for many years by the New Albany and Paoli Turnpike Company, will become a free turnpike.

RACINE, WIS.—The Holbrook-Armstrong Company of this city is building three chassis from designs by a Chicago concern. Reports that the company will engage in the business of building complete cars are denied although practically all parts are now being made.



New plant now in course of erection on Jefferson Avenue, Detroit, for the Hudson Motor Car Co.



B. O. Tilden's transcontinental Stoddard-Dayton car at the finish of its 26,000-mile tour in the interest of sanitation

INDIANAPOLIS, IND.—Thomas Marshall of Detroit, Mich., has been appointed general manager for the United Motor Indianapolis Company. He succeeds Jack Hayden, who has been obliged to retire on account of ill health.

INDIANAPOLIS, IND.—Suits brought in the federal court here by Thomas J. Lindsay and Willard Harmon against the Cadillac Automobile Company and the Westcott Motor Car Company have been dismissed. Infringement of patents covering a bevel-gear floating type of axle was charged.

CAMBRIDGE, ILL.—P. A. Johnson, who has the Maxwell line for Henry, Stark and Peoria counties for the coming season, will have a garage and salesroom in Peoria for 1912. Mr. Johnson will assume the management of the Cambridge office and devote part of his time to the Peoria office.

AKRON, O.—John W. Thomas, newly-appointed general superintendent of the Firestone Tire & Rubber Company, was inducted into office with a banquet of department heads of the company last week. The position which Mr. Thomas occupies is one that has been created by business growth.

NEW YORK CITY—Albert J. Ditman, who has been connected with the sales department of the Studebaker Company for eight years, has become a member of the firm of the Whiting Motor Company which handles the Cunningham and Mercer cars and the Sandusky motor truck at 1802 Broadway.

ST. LOUIS, MO.—The addition which the Moon Motor Car Company is making to its factory will increase the capacity of the plant 25 per cent., though owing to the fact that the space will be used to relieve the congested departments, it will increase the capacity of the factory, as far as production is concerned, 40 per cent.

BOSTON, MASS.—Fred Harrington, well known in local motor circles, has entered the commercial field and is now a member of the salesforce of the Robert Harrison Motor Truck Company of South Boston.

COLUMBUS, O.—J. A. Sherer, registrar of the Ohio State Automobile Department, has received applications for about 1200 sets of number plates for 1912 registration. Up to date the department has distributed 45,671 sets of number plates for 1911 registration or more than 10,000 ahead of the number given out in 1910.

CLEVELAND, O.—During the past few weeks the F. B. Stearns Company of this city has added the following representative dealers to its list: The Pence Automobile Company of Minneapolis, Minn.; the Fisher-Gibson Company of Indianapolis, Ind., and the McDuffee Motor Car Company of Denver, Col.

INDIANAPOLIS, IND.—The Hoosier Motor Club of Indianapolis has been incorporated. Incorporators named in the charter, which is granted under the voluntary association act without capital stock, are Charles A. Bookwalter, H. O. Smith, Joseph W. Selvage, C. W. Sedwick, N. H. Price, Bert A. Boyd and Homer McKee.

SAN FRANCISCO, CAL.—R. H. Ingersoll has been appointed manager of the Keaton Vulcanizing Works, distributors of Swinehart tires in northern California. For the past few years he has been manager of the Diamond Rubber Company's uptown branch. That position has now been filled by the appointment of J. A. Jones.

LOS ANGELES, CAL.—J. M. Cummings, manager of the western district of the Michelin Tire Company, has opened a sales warehouse at 749 South San Pedro street in this city. Business will be conducted on the wholesale plan. J. C. Wells, formerly of the San Francisco branch, will be in charge.

ANDERSON, IND.—Roy Watts, well known in the gas engine trade, has joined the forces of the Remy Electric Company, of this city, as a special traveling representative. Mr. Watts was formerly power apparatus manager and engineer for the Western Electric Company.

BUFFALO, N. Y.—The Whyland-Nelson Motor Car Company has established its plant at 49-53 Illinois street, this city, where it will manufacture light-weight passenger automobiles with convertible light delivery car attachment. Frank V. Whyland, formerly with the Superior Motor Truck Company, is president and manager.

GENESEO, ILL. — Weimer's Garage has taken the Overland line for part of Henry County. I. N. McBroom has taken on the entire Clark line for all of Henry and part of Mercer counties for the coming season. The Geneseo Garage has made arrangements with the P. W. Kempster Company, of Prophetstown, Ill., to handle part of Henry County on the Buick line.

SYRACUSE, N. Y.—At the annual meeting of the stockholders of the Chase Motor Truck Company, Nov. 8, the following directors were elected: A. C. Chase, A. M. Chase, L. O. Bucklin, H. P. Bellinger and E. C. Witherby. The directors elected the following officers: President, A. M. Chase, vice-president, H. P. Bellinger, and secretary and treasurer, E. A. Kingsbury.

BEAVER DAM, WIS.—E. O. Parker, president of the Waldron Automobile Manufacturing Company, of Waldron, Ill., is negotiating with the Beaver Dam Advancement Association for the removal of the plant to this city. The company manufactures a combination motor car for business and pleasure purposes, farm tractor, stationary engine, etc. Beaver Dam is an agricultural implement center.

WALTHAM, MASS.—The Metz Company of this city has secured another building near its plant—the former home of Gov. Gore of Massachusetts. The general offices have been transferred to this building which will be used as an administration headquarters, giving the space in the factory over to manufacturing. Next spring the company plans to build a new structure on the recently acquired ground.

SAN FRANCISCO, CAL.—John H. Eagal, vice-president of the Oldsmobile Company of California and manager of the Oldsmobile branch in Los Angeles, has been appointed general Pacific Coast representative of the Olds Motor Works, of Lansing, Mich., and manager of the new San Francisco branch. David L. Whitford has been transferred from San Francisco to Los Angeles, where he will be in charge of the Southern California territory. Eagal's district will be California, Oregon, Washington, Idaho, Nevada and Arizona. W. Folberth, the Oldsmobile factory engineer, will make his headquarters in San Francisco.

BALTIMORE, MD.—Since Commissioner of Motor Vehicles John E. George took office a net fund from motor car licenses has been turned over to the State treasury. One-fifth of this amount goes to the city of Baltimore and the remainder to the various counties for oiling, maintaining and repairing modern roads being built throughout the State.

COLUMBUS, O.—The Ohio State Automobile Department is preparing to move from the Harrison building on High street to the New Hartman building, corner of State and Third streets. Several rooms have been leased on the third floor for the executive and bookkeeping offices and a room on the ground floor will be used as a shipping-room for the number plates. The department will be moved about December 1.

NEW YORK CITY—The Packard Motor Car Company, of Detroit, has sold $2,000,000 5-year, 5 per cent. notes, maturing Dec., 1916, to W. A. Read & Company. These notes are a first claim on the assets of the company, which are carried on the books at over $15,000,000. The purpose of the company in selling these notes was to retire bank loans incurred in financing development and expansion work, and to provide additional working capital.

BOSTON, MASS.—Manager Harold D. Bornstein, of the New England branch of the Velie, has arranged to move about January 1 from his present quarters on Massachusetts avenue to a building on Boylston street, now being remodeled. The lease of the present quarters does not expire until next September, but as the Stoddard-Dayton Company is to take it over Manager Bornstein decided it would be a good plan to move as soon as possible.

BOSTON, MASS.—The local branch of the Velie Motor Car Company has appointed the following as agents for the Velie: The Shean Auto Station for Springfield, Mass., and vicinity; Amos J. Shorey for Bangor, Me., and northern Maine; J. T. Curtiss & Company for Hartford, Conn., and southern Connecticut; George H. Snell for Attleboro, Mass., and vicinity; Arthur Beharrell for Lowell, Mass.; Walter B. Johnson for the State of Vermont; Lord Bros. for Tifton, N. H., and vicinity.

BOSTON, MASS.—Manager Pruden of the New England branch of the Kissell Kar Company has approved plans for a new building to be erected for the company on Commonwealth avenue. It will be two stories in height and 200 feet long, giving ample room for salesrooms and a service depot. While the new building is being erected the branch will move temporarily to the motor mart in Park Square, as the J. W. Maguire Company, agent for the Pierce Arrow cars, located next door, has leased the present quarters of the Kissell Kar Company as an addition to its salesrooms.

Automobile Incorporations

AUTOMOBILES AND PARTS

BROOKLYN, N. Y.—Bedford-Bergen Auto Exchange; capital, $25,000; to manufacture machinery for automobiles. Incorporators: Ralph Brown, Max Keve, Chas. Goldstein.

BOSTON, MASS.—White, Binford & Robenson Motor Co.; capital, $20,000; to manufacture automobiles. Incorporators: Albert C. White, Jr., Cecil P. Robenson, Henry O. Cushman.

BUFFALO, N. Y.—Whyland-Nelson Motor Car Co.; capital, $10,000; to make automobiles and engines. Incorporators: Frank W. Whyland, Joel W. Nelson.

CHARLESTON, S. C.—Kanawha Auto Truck Co.; capital, $50,000; to build and sell freight automobiles. Incorporators: W. S. Roberts, J. L. Sydenstricker, George F. Gates, D. S. Gunther.

COLUMBIA, S. C.—Consolidated Auto Co.; capital, $5,000; to sell automobiles. Incorporators: J. B. Roddey, John J. Cain and others.

COLUMBUS, OHIO—Union Sales Co.; capital, $500,000; to manufacture automobiles.

MARION, IND.—Auto Machine Co.; capital, $10,000; to make and repair automobiles. Incorporators: G. D. Lindsay, B. A. Tong, R. E. Breed, Jr.

PITTSBURGH, PA.—Large Motor Truck Co.; capital, $25,000; to manufacture freight automobiles. Incorporator: Edwin L. Atkinson.

PITTSBURGH, PA.—R. C. H. Auto Co.; to sell automobiles. Incorporator: Kenneth S. Burley.

PITTSBURGH, PA.—Krupp Motor Co.; capital, $250,000; to make automobiles and engines of all kinds.

ROME, GA.—Seay-McCartha Automobile Co.; capital, $3,000; to sell automobiles. Incorporators: S. R. McCartha, R. M. McCartha, John L. Seay.

ST. LOUIS, MO.—Mack Motor Truck Co.; capital, $25,000; to make freight automobiles. Incorporators: William R. Bush, Frank J. Bush, Knox Taussig.

SEWAREN, N. J.—Motor Vehicle & Marine Construction Co.; capital, $15,000; to make automobiles. Incorporators: Henry E. Acker, Albert B. Boynton, William C. Muir.

SPRINGFIELD, MASS.—Western Massachusetts Cadillac Co.; capital, $10,000; to sell automobiles. Incorporators: Edward R. Clark, Robert A. Knight.

SYRACUSE, N. Y.—Francis Motor Sales Co.; $5,000; to sell automobiles. Incorporators: Guy M. Francis, Richtmeyer Hubbell, Chas. E. Nichols.

NEW YORK CITY—Volkmar Auto Starter Co.; capital, $20,000; to manufacture automobile starting devices. Incorporators: Bernhard Volkmar, Edward Giegerich, Wm. H. Giegerich.

AUTOMOBILE GARAGES AND ACCESSORIES

BALDWIN, N. Y.—Baldwin Garage; capital, $1,000; to conduct a general garage business. Incorporators: Charles H. Southard, Mary A. Southard, Wilford S. Southard.

BIRMINGHAM, ALA.—Auto Tire & Cycle Co.; capital, $2,000; to manufacture automobile tires. Incorporators: Reese Stansel, W. R. Grimes.

BRADDOCK, PA.—Miles Motor Tire Spring Co.; capital, $200,000; to make automobiles and trucks. Incorporators: Chas. W. Dressler, Thomas G. Aten, Chas. L. Balsyer, Zenob A. Delwart, Fred Miles, M. R. Myers.

CHICAGO, ILL.—Motor Service Corporation; capital, $10,000. Incorporators: R. Oehmig, F. B. Burl, F. R. Page.

CINCINNATI, OHIO—Fisher Auto & Service Co.; capital, $30,000; to deal in automobiles, trucks, garages, accessories and to do a general garage business. Incorporators: Arthur F. Fisher, H. J. Guckenberger, George C. Bauer, George Guckenberger, William J. Fleming.

CONNEAUT, OHIO—Trio Horn Mfg. Co.; capital, $25,000; to manufacture automobile horns and other accessories. Incorporators: Ira E. Stump, B. E. Thayer, W. A. Middleton, Fred Eckert, F. B. Kavanaugh.

INDIANA HARBOR, IND.—Central Auto Supply Co.; capital, $600; to deal in automoible supplies and accessories. Incorporators: C. C. Robinson, F. E. Stephens, B. S. Gardner.

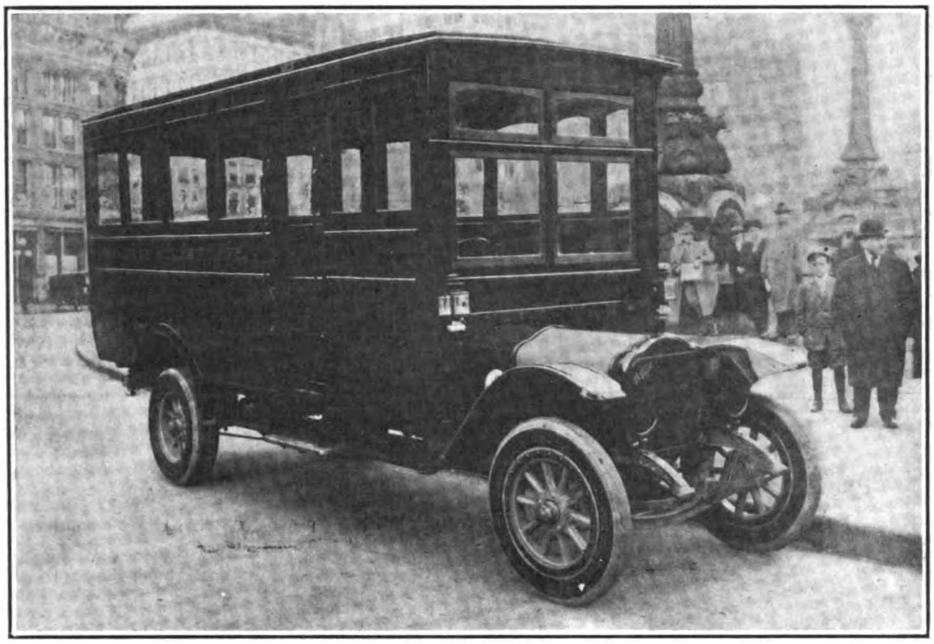
NEW YORK CITY—Advance Motor Express Co.; capital, $5,000; to rent automobiles, express and transfer wagons. Incorporators: H. S. De Camp, H. L. Graft, J. I. Doherty.

NEW YORK CITY—Trautman Air Rubber Tube Co.; capital, $100,000; to manufacture automobile tires. Incorporators. Ira Trautman, August V. Denis, Wm. G. Newhall.

NEW YORK CITY—Automobile Sundries Co.; capital, $10,000; to make and sell automobiles, accessories and supplies. Incorporators: Geo. F. Merritt, John E. Waltz, Tho. M. Crisp.

Building of the Pence Automobile Co., Stearns-Knight distributors in Minneapolis

OF INTEREST to the INDUSTRY



Type of pay-enter motor bus made by the White Company for Indianapolis company

INDIANAPOLIS, IND. — The Rapid Transit Motor Company has begun the operation of a motor bus line on North Meridian street, one of the finest residence districts in the city. The chassis of these vehicles are of the 1½-ton class made by the White Company, of Cleveland, O. The buses are of the pay-as-you-enter type, seating eighteen passengers each. They are provided with electric fans for summer service, while a heating system is installed for winter use. The route they will cover is 3½ miles long, and each fare is 10 cents.

PONTIAC, MICH.—The Welch Motor Car Company will begin work at once on an addition to its factory. It will measure 40 x 100 feet.

JEFFERSON, WIS.—Ground has been broken here for the new plant of the Kenzler-Waverley Motor Company. It is to be 60 x 100 feet.

JERSEY CITY, N. J.—The Autoparts Manufacturing Company has removed from 56 Pine street, New York, to 810 West Side avenue, in this city.

DETROIT, MICH.—Joseph E. Warren has been appointed chief of district managers for the Metzger Motor Company of this city which manufactures the Everitt car.

HAMILTON, ONT.—The Republic Motor Car Company has completed foundations for two factory buildings to measure respectively 60 x 300 feet and 80 x 100 feet.

ST. LOUIS, MO.—The General Novelty Company, manufacturer of Bullfrog horn reeds, has removed to Twenty-third and Locust streets, with the Auto Parts Sales Company.

PHILADELPHIA. — Ballinger and Perrot, architects, are preparing plans for a $100,000 automobile factory which the Otto Gas Engine Company contemplates erecting at Mount Holly.

ANDERSON, IND.—The Remy Electric Company of this city has purchased the plant and patents of the R. G. Peters Company of Grand Rapids, Mich., and the Peters plant will be consolidated with the one here.

INDIANAPOLIS, IND.—The American Motors Company has moved part of its factory organization into the new building at Meridian street and Belt railroad in this city. All the buildings previously occupied are retained.

DETROIT, MICH.—The Metzger Motor Car Company, which makes the Everitt car, is rapidly pushing to completion the addition to its factory. The building will be finished and ready for occupancy within the next 30 days.

TOLEDO, O.—The Champion Spark Plug Company of this city has purchased a 1 1-2 acre building site on the Lake Shore and Michigan Central Railroad and is constructing a modern, fireproof plant. The company has also placed orders for a large addition to its automatic machinery equipment.

AKRON, O.—The Goodyear Tire & Rubber Company, closed for three weeks to make changes in equipment and prepare for the Winter season of 1912, resumed operations Nov. 1, with 2,500 men. Officers of the company say the busiest season in the company's history is at hand. The recent improvements and additions give 1,000,000 feet of floor space for use in the new campaign.

ST. LOUIS, MO.—The new pumping station to be erected in this city by the Prest-O-Lite Company will occupy a site 180 x 475 feet on the south side of Duncan avenue, between Vaudeventer avenue and Sarah street. It is the intention to have the St. Louis station take care of the middle and southwestern territory in repairing and recharging gas tanks.

SYRACUSE, N. Y.—Robert M. Barker has been made advertising manager of the Chase Motor Truck Company of this city. Mr. Barker is a graduate of Harvard, has traveled widely and his experience in the advertising field has been extensive.

OOSTBURG, WIS.—The Yale Mfg. & Sales Company, Manufacturers' Home building, Milwaukee, which manufactures automobile accessories and signal devices, has purchased the buildings and real-estate of the Oostburg Foundry Company, and will move its manufacturing plant to this place. The general offices will remain in Milwaukee.

MOLINE, ILL.—Benefits amounting to $1614 were paid out during the last fiscal year by the Velie Employes' Aid Association, according to the treasurer's report at the annual meeting of the society. Benefits were paid to 115 members of the association, which is composed of 300 employes of the Velie Carriage and Velie Motor Vehicle Works.

WAKEFIELD, MASS.—At the regular town meeting held this week a special committee appointed to investigate motor apparatus for fire departments sent in its report that a combination chemical and ladder truck costing $5800 should be added to the town's fire equipment. It is to be kept at the central station. The town now has a motor chemical and a motor hose wagon. The committee's report will be accepted.

WASHINGTON, D. C.—The Pope Automobile Company, agent for the Pope-Hartford, Columbus Electric and Marathon, is making extensive improvements in its salesrooms at 817-19 Fourteenth street, N. W.

CHARLOTTE, S. C.—The Diamond Rubber Company, of Akron, O., has opened a subbranch under the temporary direction of J. F. Banier.

PATENTS GONE TO ISSUE

CONTROLLING MECHANISM—A steering wheel for operating steering knuckle and carbureter throttle.

5. The patent refers to a mechanism as shown in Fig. 1, comprising the combination of a steering-post with a rotatable shaft for controlling the movement of the carbureter throttle. This shaft is rotated through an oscillating lever arm. A rotatable shaft serves to actuate the spark-controlling device, and a hand grip carried on the upwardly extended axis of the rotatable lever abovementioned to rotate the shaft. The hand grip may be made to operate the lever which moves simultaneously with it, while it is capable of being rotated on its axis independently of the movement of the lever arm.

No. 1,007,673—To Howard E. Coffin, assignor to E. R. Thomas Detroit Company, Detroit, Mich. Granted November 7, 1911; filed August 4, 1906.

LIQUID FUEL ENGINE—In which the crankcase serves as a compression chamber for air.

1. This engine (Fig. 2) consists of a cylinder and a casing secured thereto to form a crankcase, which is provided with an inlet valve. A piston rotating in the cylinder compresses air in the crankcase, which communicates with the cylinder through a pipe containing an evaporator. This is heated by the hot gases exhausted from the cylinder. A metal gauze net is inserted in the pipe, between crankcase and evaporator, and the pipe is provided with a pit forming part of the channel between the metal gauze and the evaporator to collect waste fuel from the latter.

No. 1,008,199—To Olaf Leonhardt Riegels, Christiania, Norway. Granted November 7, 1911; filed February 16, 1909.

INTERNAL-COMBUSTION MOTOR—Cylinders are in opposed position and each pair served by common means.

2. The patent relates to a multi-cylinder engine (Fig. 3) consisting of a base, a number of cylinders arranged in pairs with each two cylinders of a pair in angular relation, a crankshaft in the base with a single throw for each pair of cylinders and means for actuating the valves of the engine cylinders. These means are: a camshaft which is journaled on the casing between the cylinders of the pairs parallel to the shaft and a cam on the camshaft for each pair of cylinders. A cover is detachably secured on the casing over the camshaft and has guide apertures parallel to each cylinder in the plane of rotation of the cam provided for it. A finger is provided whose inner end is journaled in mating half-bearings formed in the meeting faces of the cover and base, and whose outer end bears on the camshaft in the plane of rotation of the cam; there is one valve tappet-rod for each cylinder, and it is adapted to reciprocate in the guide parallel to the cylinder. A plunger for a companion cylinder is reciprocable in the companion guide aperture of the cover with its inner end resting on a finger between the ends thereof.

No. 1,007,842—To Ellsworth H. Belknap and John W. Swartz, Detroit, Mich., assignors to Golden, Belknap and Swartz Co., Detroit, Mich. Granted November 7, 1911; filed September 15, 1910.

ACETYLENE GENERATOR—A system applicable to the generation of large quantities of acetylene gas.

3. The apparatus protected by this patent (Fig. 4) comprises an acetylene generator in which is mounted a carbide holder having an outlet, the generator being connected with a gas tank in which a gas-bell is mounted free to slide. Close to the outlet mentioned a shutter is mounted and able to swing freely, thus being adapted to control the flow of carbide through the outlet. A pair of link devices in the generator which are jointed together at their lower ends have their upper ends connected to the shutter so as to swing the same. A lever is provided which has a slotted end adjustably connected with the gas bell and controlled thereby, and this lever is connected to the upper end of the two link devices by another link, this latter link swinging on the upper end of the two link devices during the movement of the gas-bell and lever after the shutter has reached the end of its swinging movement.

No. 1,007,909—To Joseph O. Angermeier, Inglefield, Ind. Granted November 7, 1911; filed April 15, 1910.

LIFTING JACK—In which a piston is lifted by means of a fluid under pressure.

2. This jack is a combination of a lower chambered member with a vertical cylinder containing a piston on which a prop is seated. The prop is normally held yieldingly in an upright position, but may be swung down when required. Means are provided to center the lower end of the prop on the piston and for admitting an actuating fluid into the chamber below the piston.

No. 1,008,138—To George C. Hale, Kansas City, Mo. Granted November 7, 1911; filed June 3, 1911.

CLUTCH—Being of the cone type.

This clutch comprises a drive-shaft to which is secured a clutch member provided with a rim carrying studs. The stem of the shaft carries a spring seat. The driven clutch member has a sleeve and is mounted on the drive-shaft stem; its rim carries pins. A spring surrounds the drive-shaft stem between the driven member and the spring seat. The sleeve mentioned is encircled by a collar having radial arms provided with perforations which receive the pins on the rim of the driven clutch member. Means are provided for shifting the collar so as to engage the radial arms with or disengage them from the studs on the rim of the clutch member of the drive shaft.

No. 1,007,977—To Earle T. Robinson, St. Louis, Mo. Granted November 7, 1911; filed October 22, 1910.

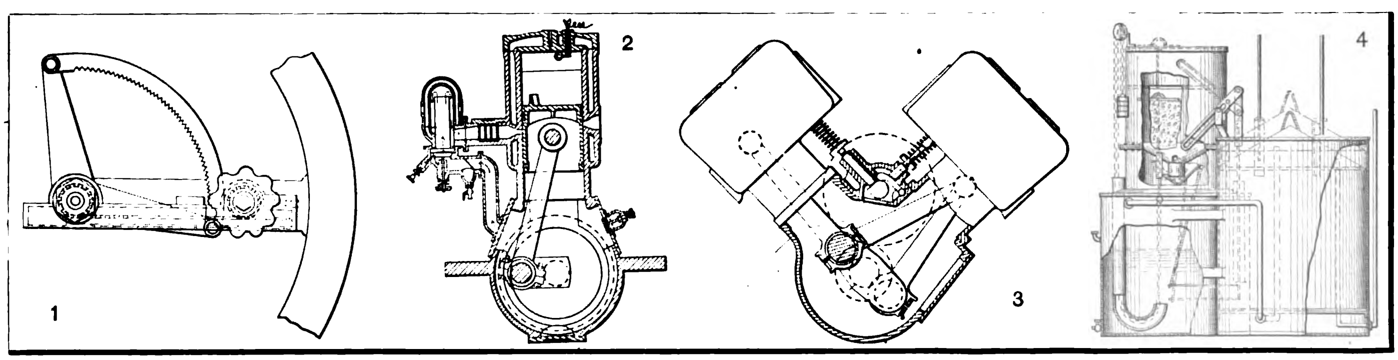


Fig. 1—Coffin steering mechanism. Fig. 2—Riegels' liquid fuel engine. Fig. 3—Belknap-Swartz motor. Fig. 4—Angermeier acetylene generator

Newest Ideas Among the Accessories

Turner Gasoline Torches

BLOW torches, as illustrated in Figs. 1 and 2, are used to produce such hot gasoline-air flames as are of use in brazing, tempering, annealing and melting work, not forgetting welding and soldering jobs. The apparatuses here shown are made by the Turner Brass Works, Sycamore, Ill. The devices consist of seamless steel tanks, into which a sufficient quantity of the fuel is filled. Then the space above the level of the liquid is filled with compressed air by either working the pump attached to the smaller types of torch, or connecting the air inlet of the tank with a source of compressed air. After the pressure of the air inside the tank has reached a sufficiently high degree, as indicated by the gauge accompanying the torch, the air inlet valve is closed, and the apparatus is ready for operation.

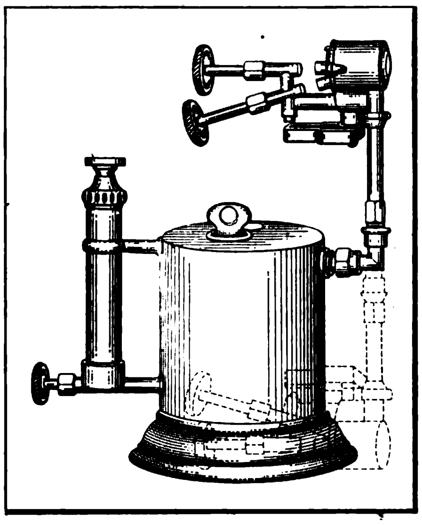

Fig. 1—Blow torch designed for use of gasoline

If the outlet of the tank is opened by means of the proper valve, the gasoline or kerosene used as fuel is pushed out of the tank at a high rate of speed and if lighted provides a hot flame. The machine shown in Fig. 1 is intended for the use of gasoline only, and a double jet is used in it for producing the very high temperature required for the work. It is claimed that this type of torch will do the work of a common blowtorch in half the time consumed by the latter.

In Fig. 2 is illustrated the Turner hot-blast brazing machine No. 68A, which is built for the use of either gasoline or kerosene. The principle of construction and operation of this machine are identical with those of the smaller type, to which it is very much superior, however, as far as capacity is concerned. The large size may burn at full blast for 5 hours, without pausing or refilling. One feature distinguishing it from the smaller machine is the use of two burners connected to the tank by oiltight, copper-covered tubing attached to two valves on the top of the tank. Either valve may be used independently or in unison with the other, giving one or two very hot flames.

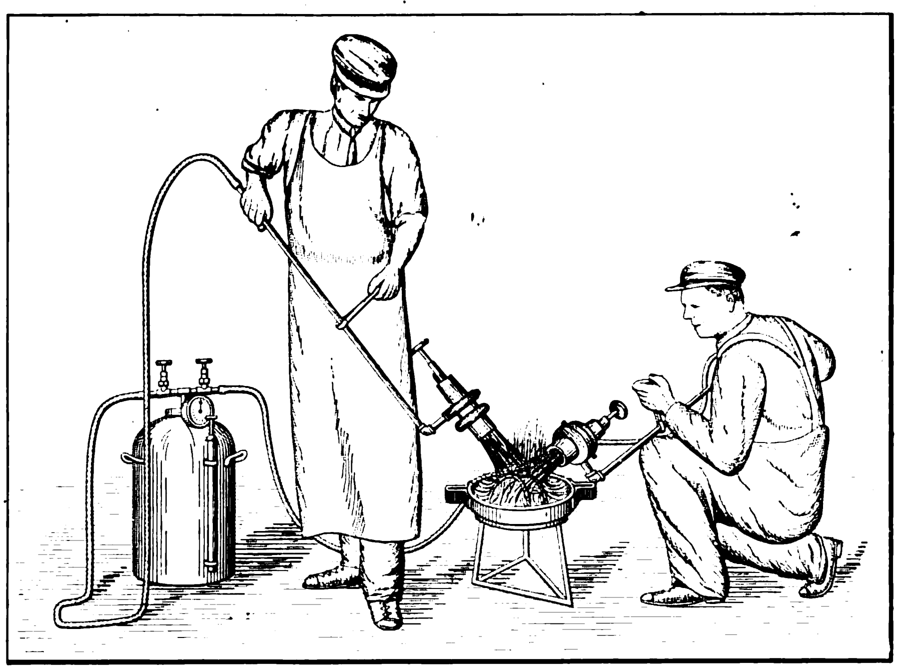

Fig. 2—Turner hot-blast brazing machine in which either gasoline or kerosene is used

Langrehr Safety Device

The Langrehr explosion-safe fuel receptacle shown in Fig. 3 is constructed with the object of protecting gasoline or similarly combustible fuels in a can from spontaneous combustion which might arise by the admittance of a flame into the inner space of the receptacle. Broadly speaking, the principle of the Davy lamp has been utilized in this device, but has undergone considerable modifications, before it was found available for efficient service. In the Davy lamp a wire-mesh screen is used to separate the flame from the explosive gases which otherwise would have free access to it. Should such gases enter the lamp through the screen and ignite, they will be prevented from firing back out of the lamp space by the cooling effect of the wire-gauze screen.

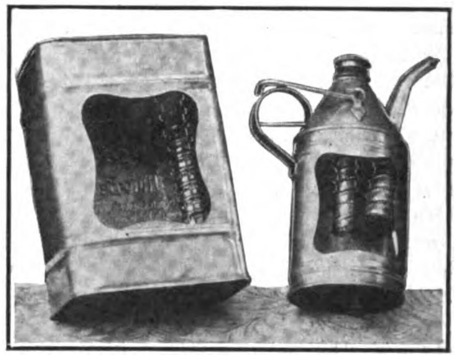

Fig. 3—Langrehr safety fuel receptacle

In the Langrehr device the number of openings in the partition between flame and fuel is reduced, thus impeding the progress of the flame to a much higher extent than a wire screen; the increased metal surface provides an augmented cooling effect.

As Fig. 3 shows, the Langrehr device consists of a series of corrugated and smooth strips of metal of suitable strength and elasticity, forming passages. The metal strips series are rolled in tube shape. By the use of a tube of suitable length, the total free cross section of the passages is almost equal in area to the aperture of the vessel, to which the tube is connected. The massive metal strips forming the passages cool the burning gases, if such should enter the tube, to such an extent that it is impossible for the flame to reach the interior of the vessel in which the combustible substance is contained.

The American representative of the German inventor of this device is Dr. Edward D. Feldman, Berlin Chemical Laboratories, 560 West 171st street, New York City.

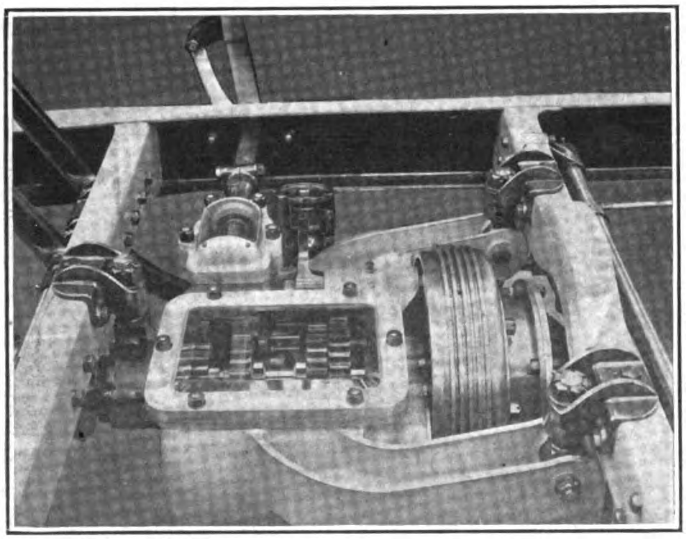
7—Some novelties in the shape and arrangement of the head and sidelights seen on the new Daimler

LONDON, Nov. 14—Despite the fact that, so far as number of new chassis is concerned, the show is not up to the level of previous years, there is a great wealth of detail improvement to record, innumerable small alterations which, although passed over by the casual visitor, make up in the aggregate a very valuable advance in automobile construction. It seems to be the case that the designer has at last become satisfied with the efficiency of the main components and has thereupon cast round for details which need attention. Of course, he has not had far to look, for the average private owner could quickly compile a list of fifty matters requiring some improvement.

The 15.9 car is about the average for medium-powered fours, yet, curiously enough, this actual rating has fallen considerably from its former place of prominence. For general touring work over all kinds of country and for town carriages the 90-millimeter (20-horsepower) engine is gaining ground, while the man who just wants a lightweight four for runabout and easy touring work finds his requirements amply fulfilled by the many small 12-horsepower cars which are now produced. Among the still smaller cars may be mentioned the Humber Duocar and the Enfield Autovette or the Phanomobile three-wheeler, all these round the £100 mark.

As regards number of cylinders, the four has about two-thirds of the total, the six-cylinder engine having a sixth of the business, while the remainder is divided between the single the twin and the eight-cylinder model of the De Dion firm. The one-cylinder motor is staunchly upheld by the Rover, Swift and De Dion, while of the twin the Riley firm is the best known exponent. The single and the twin engine has each its own class of followers, and one cannot forsee the likelihood of either type going out of fashion.

The valve controversy has broken out more fiercely than ever; in fact, the situation is almost as exciting as when, in 1908, the Knight engine was presented to the British public by the Daimler company. The two intervening exhibitions have seen no further complication of the issue, though, of course, new licensees of the sleeve-valve engine have made their bow each year. But now the whole of the industry seems likely to be drawn into the struggle, for new claimants for public favor are to be found in the Argyll firm, with its single-sleeve engine; in the Darracq rotary valve motor and in the piston valve design of the Itala concern. And, meanwhile, we have the Crowdy piston valve engine as another competitor. Incidentally, it is announced that Messrs. Knight and Holbourne, after inspecting the new Argyll sleeve-valve engine and taking advice about the patents, deem the Argyll company to be infringing the Knight patents. This news has astonished the motor trade in Great Britain, because it suggests that Mr. Knight must be claiming a master patent over moving cylinder walls. But for that basic resemblance the Argyll and Knight motors seem quite distinct. Meantime the Argyll company is indemnifying all purchasers of its single-sleeve



Sunbeam gearset, showing method of attaching to frame cross member

valve engines against penalty for infringement of patent, and the Piccard-Pictet firm, of Switzerland, which is using the Argyll patent, is following the example.

On the side of the Knight army, additional strength has been acquired by the arrival of two new Deasy models, by the new small Panhard (which means that the French concern is going to concentrate on the sleeve-valve engine) and by the adoption of the engine by the Stoewer company.

Monobloc Construction Favored

With regard to the technical details of the engines at the show, it is clear, in the first place, that single-cylinder castings are not favored, save by Austin and one or two other firms. Parr castings are general except for engines under 15 horsepower, where the monobloc construction is a strong rival. For six-cylinder engines two pairs of three cylinders each form the usual practice. Daimler and Napier are two exceptions; the former engines have the exhaust branches coupled up in two threes so that two consecutive firing cylinders never exhaust into the same branch. The V arrangement of cylinders is found in the Riley, the Delahaye (a six-cylinder) and the eight-cylinder De Dion. About the only example of desaxé placing of the cylinders is afforded by the two new Rover models.

The average ratio of stroke to bore shows a distinct increase. As the top limit there is the Sizaire 15, with stroke of 170 for a 70-millimeter bore, while the only engine with bore greater than stroke is to be found on the N. E. C. stand. The two Lanchester models, four and six cylinders, have equal bore and stroke of 4 inches, and the Opel 12 supplies a case of the stroke being shortened this year from 120 to 100 millimeters; otherwise the tendency is toward bigger crankshaft throws. Examples of long-stroke engines are the Sunbeam, 90 by 160, and the La Buire, 80 by 160.

Chain-driven crankshafts are all the rage. For this, at least, one must credit the Knight-Daimler engines. Probably over two-thirds of all the engines in the show are thus equipped. Of the others the Spyker and the Fiat 15 horsepower have worm-driven shafts. Overhead camshafts are employed in the engines of the Maudslay and Germain firms, though rumor has it that the latter engines will soon be valveless.

The above practice has silence of running as its object; smoothness of running is now better insured by the balancing of flywheels—a patent, but generally unsuspected, cause of vibration. As for the periodic vibration of crankshafts, the previous existence of this trouble is evident from the importance of the firms which now employ vibration dampers. Rolls-Royce, Daimler and Deasy are three examples.

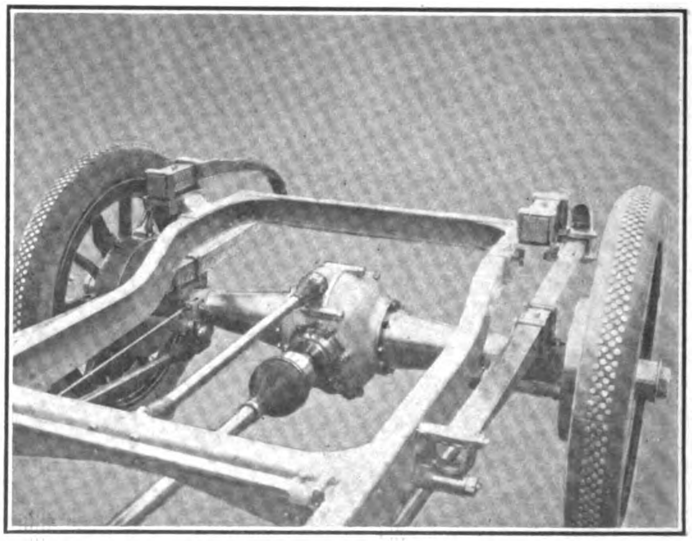
Ignition shows improvement in regard to the use of self-advancing magnetos, while a novelty which looks like having a future before it is the Simms arrangement of combined ignition and lighting dynamo. A similar dual service is rendered by the Ford flywheel magneto.

Some Additional Refinements Noticed

Other engine tendencies are revealed by the increased adoption of thermo-syphon circulation (Vauxhall has reverted to the pump, however) by the reduction in the number of external water pipes (compressed rubber rings being used between adjacent cylinder cases) and by the remarkable increase in the employment of proprietary carbureters.

The engine is always regarded as the life of the car; hence we have dealt with it here at some length. For the transmission details a shorter notice must suffice. New types of clutches are to be seen in the Vauxhall disc arrangement, which has powdered graphite as the lubricant, in the Panhard cast iron and fiber disc clutch, and in the leather and oil cone clutch of the new Humber models. A variation of the latter is provided by the Rolls-Royce and Crossley designs, wherein a few drops of oil are injected into the clutch from the engine supply each time the pedal is depressed.

A radical departure from previous practice in gearbox construction is evidenced by the B. S. A. arrangement of combined rear axle and speed gearbox, a design also used by the Sheffield



Rear suspension of the 1912 Delahaye

Simplex firm. This method offers distinct advantages in the way of simplicity and also in regard to silence of the indirect gears, and it is by no means unlikely that the custom will have a considerable vogue in the future. In gearboxes of the standard type the layshaft is often placed below the main shaft, particularly in those boxes designed for the use of oil as the lubricant. The Maudslay chain-driven gear box is an example of a novel but highly satisfactory design, while epicyclic gearing is still retained by Lanchester. All Talbot gear boxes have a sprag device, a once universal fitting.

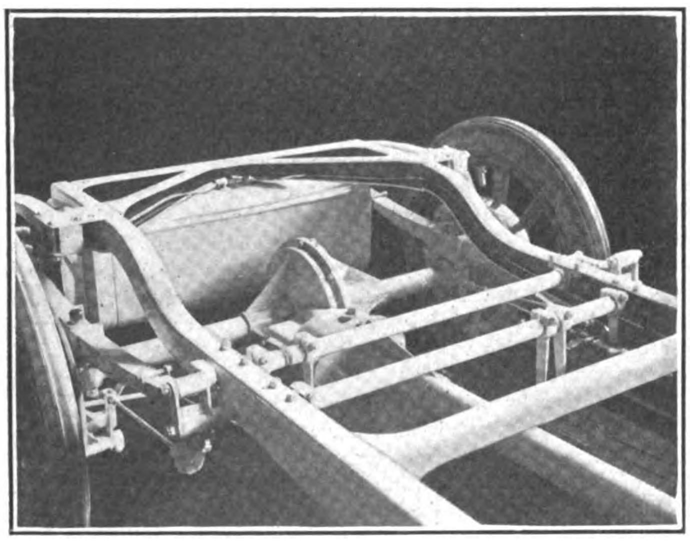
Despite the announcement by a few firms (notably Sunbeam and Crowdy) that they intended to abandon worm gearing for bevel, the former method of rear axle drive increases in popularity, Minerva and the Humber being two prominent accessions to the now lengthy list. In the Thorneycroft, Star and Straker Squire lists one worm-driven model (for closed carriages) is included. The Armstrong Whitworth rear axle has spiral gear drive, while another novelty in this chassis component is found in the direct drive on the third and fourth speed provided on the 15-horsepower Lancia car.

It seems clear that eventually both brake sets will be placed at the road wheels. Front wheel braking is hardly popular as yet, but this practice will certainly come into general favor before long. Meantime many makers are placing both brake sets at the rear hubs, some, like Panhard's, favoring the expanding type for both, while others resemble the B. S. A. in the use of a double set of outside bands. A dozen cars have a combination of the two forms. Raybestos, or some similar lining, is becoming general, and hand adjustment may be described as almost essential. A point for criticism is the complication of the equalizing arrangements for the rear brakes; the Vauxhall suggests itself as a simple yet effective method.

Unit Construction with Three-Point Suspension

Great attention seems to have been paid to the springing. Not a few firms, such as Arrol-Johnson, Austin, Panhard, employ elliptics at the rear, while three-quarter elliptics are to be seen everywhere. Lever or other special suspension methods are common; three or four firms (Deasy and Rolls-Royce in the list) use the Lanchester type.

Adjustable steering columns and pedals indicate increased attention to the drivers' convenience, while the several additional cars fitted with engine starters show how this desirable accessory is gaining ground. Two other cars (Armstrong Whitworth and Piccard Pictet) are provided with mechanical tire pumps—useful fittings, yet doubly so are the engine-starting apparatus also supplied. A number of makes are equipped with an electric light dynamo as part of the standard equipment—the Armstrong Whitworth's and the Daimler sixes suggest themselves. Going further than this, a dozen firms supply top, screen and head

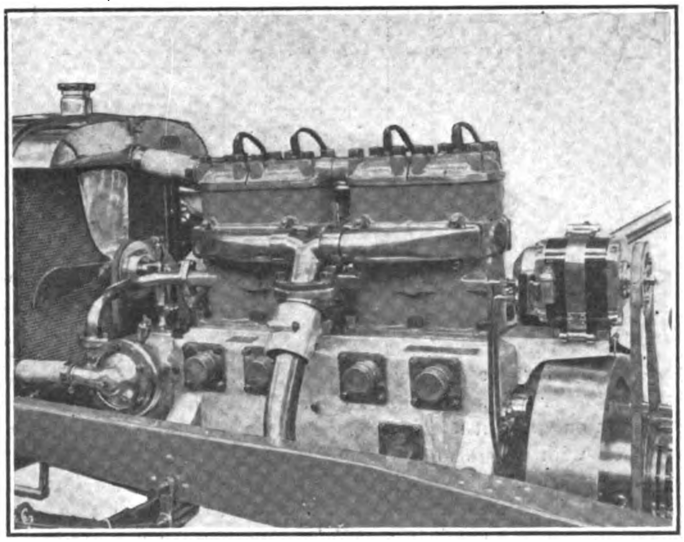


Rear suspension of the 1912 Lancia

lamps with their cars; by next Olympia we shall have arrived at that satisfactory state of affairs when every car is sold fully equipped and ready for full use, without any charge for extras.

Unit construction of motor, clutch and gearbox has been made a conspicuous feature on European cars for 1912. It is difficult to understand, in many cases, why the change has been made, for it has not tended toward accessibility, and to dismount any one of the three parts forming the unit is generally a workshop job. Three-point suspension usually goes hand in hand with unit construction, though there is really no general rule, some makers adopting the unit type to give additional rigidity to the frame, and others to gain greater flexibility. In the former case the entire unit is bolted to the frame members, while in the latter the attachment is at three points only. It should be pointed out that this unit type of construction is being found to tend towards increased noise, a droning being set up when running fast, and this naturally being accentuated when running on one of the gears. So much importance is attached to silent operation that this tendency to hum may be a serious objection.

Panhard has set the fashion by producing the new 1912 model with the 15-horsepower Knight motor on the unit system with three-point suspension. Hangers to left and right of the motor base attach to the frame members, and the rear of the gearbox is bolted to a transverse frame member, the clutch housing and gearbox coming under the footboards in a manner which, externally at least, recalls Ford design.



Carbureter side of Delaunay-Belleville motor

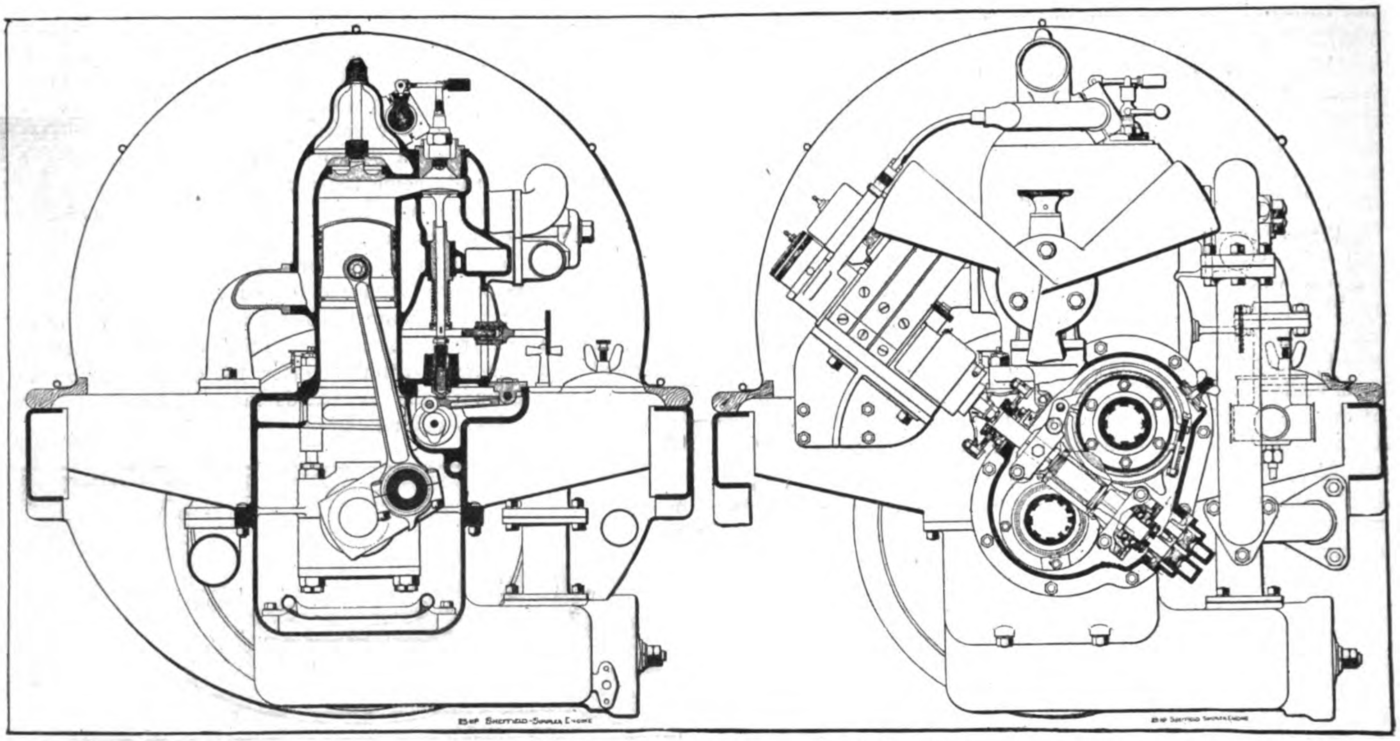
Another important example is to be found on the De Dion Bouton models. The existing types have not been changed, but where new models have been produced unit construction and three-point suspension have been adopted. There are two of these, both very small, low-powered cars intended for work as light runabouts. Hangers on the crankchamber attach the motor to the side members, and the rear of the gearbox is hung to a tubular cross member.

Fiat Offers Interesting Unit Design

A most interesting construction is to be found on a small Fiat car. The base of the crankchamber is in one casting with the complete gearbox. The base chamber itself adheres to standard lines of design, but instead of terminating at the rear with the upper portion of the crank chamber, it is flared out to form a skeleton around the flywheel and terminates in a complete gearbox. The upper portion of the crank chamber is quite orthodox, and although the cylinders are in one block with integral intake and exhaust manifolds, there is nothing startling in the design.

Lancia has an original production of a similar nature. A four-cylinder monobloc of 100 by 130 millimeter bore and stroke has the upper portion of its crankchamber and the entire gearbox in a single casting. Four hangers allow the motor base to be attached to the crankchamber, but from the rear pair of hangers the casting is continued into the gearbox, this latter having at its rear extremity two arms by which it is in turn secured to the side frames. Thus although it is a unit construction, its design further tends to stiffen the frame.

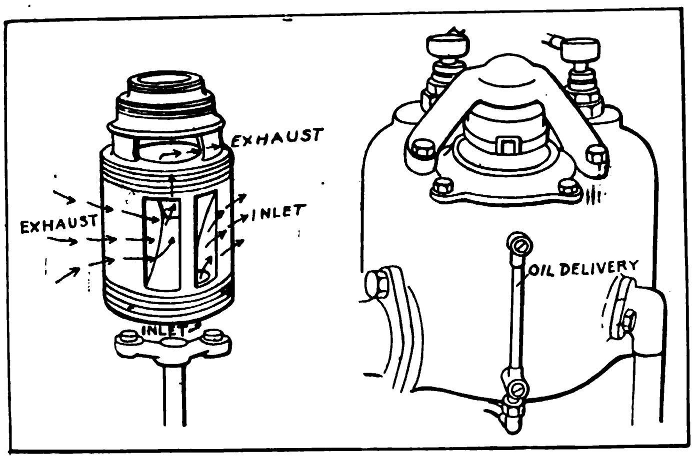
Crossley, of gas-engine fame, has a true unit construction with crankchamber forming one casting, and clutch housing and gearbox another, the two being bolted together. The entire power plant is carried on two tubular cross members, with a single point attachment at the front and two points at the rear.



Transverse section and front view of the 25-horsepower Sheffield-Simplex motor

Three-bearing crankshafts for small motors—4-inch bore or less—is by far the most common method of construction. A large number of firms, indeed, carry their mainshaft on two bearings only, but it should be pointed out that several who were satisfied with two bearings last year have gone back to three bearings. The small Fiat, of 80 by 130 mm. bore and stroke, and the small Lancia have their crankshafts carried on two ball bearings. Delage employs a ball bearing for the center of the crankshaft of his six-cylinder motor, but has anti-friction for his two end bearings. The same maker has used five ball bearings for the crankshaft of his fast runabout. However, on his standard four-cylinder models this maker uses two bearing shafts. As a general rule the English makers are not in favor of two- or three-bearing crankshafts for respectively four- and six-cylinder motors. Thus, both Crossley and Sunbeam employ five bearings for the four-cylinder motors, and Sunbeam has seven bearings for the six-cylinder monobloc.

A silent chain in place of meshing pinions is very extensively employed on cars of both English and Continental construction It is now used, for poppet valve motors, by Crossley, Sunbeam, Unic, Sizaire, Clement-Bayard, Chenard-Walker, Gregoire, Vauxhall, as well as by many others who adopted it a year ago. With the spread of monobloc casting for motors of larger and



External view of Itala distributor valve and of the valve chamber

larger size, there have been made improvements in the simplification of water, intake and exhaust piping. Lancia, Fiat and S. P. A., three of the leading Italian makes, are conspicuous in this respect by reason of intake and exhaust manifolds cast with the cylinders, and all piping abolished. In these cases the carbureter is bolted up direct to the intake manifold, the throttle being within the cylinder casting. On the Piccard-Pictet models there are separate exhaust manifolds for the two groups of cylinders, but the inner extremity of each passes into a common descending exhaust pipe.

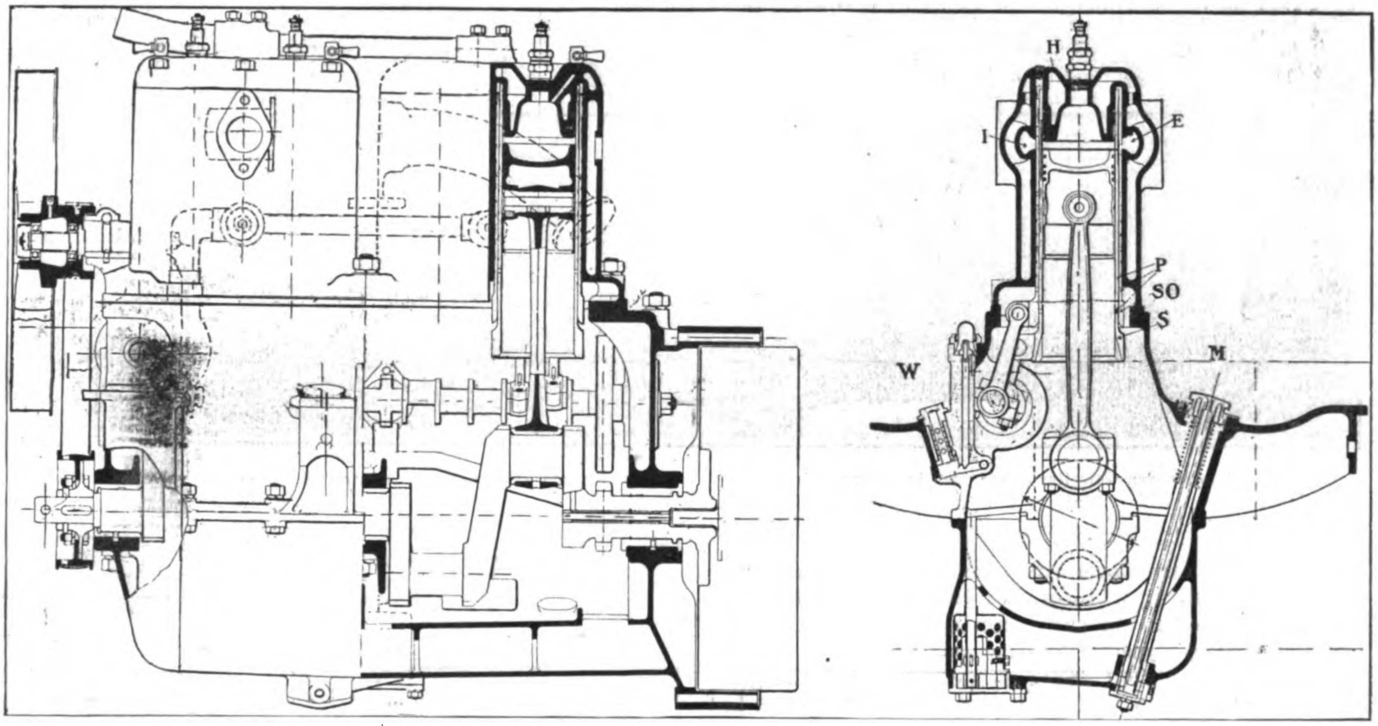
Many Chain-Driven Cam and Magneto Shafts

Crossley, the Manchester builder, has stuck to the five-bearing crankshaft. Separate chains are used for camshaft and magneto shaft, the magneto being mounted on a bracket cast on the crank chamber and having a sliding bush so that the magneto and its shaft can be moved laterally. Lubrication is forced throughout, the arrangement made for indicating the level of oil in the base being by an inclined glass tube on the outside of the base of the crank chamber. Provision is made for lubricating the spigot end of the shaft. At the end of the crankshaft a valve closes the oil way bored through the shaft; when the clutch is withdrawn—it is inverted cone type—a trigger opens this valve and allows oil to flow along the spiral groove cut on the spigot. As in many other cases, Crossley drives his fan by belt from the magneto shaft.

Wolseley has adopted chain drive for the camshaft and magneto and pump shafts. Three-point suspension has been made use of for the gearbox, while the mud pan has been abolished.

Panhard's novelty is the new Knight motor of 80 by 130 mm. bore and stroke with three-point suspension, the crank chamber being attached by the two side arms, and the gear box being bolted at the rear to a transverse frame member. Three plain bearings are used for the crankshaft, with pressure feed lubrication to the main bearings and through the bored shaft to the connecting rod ends.

Delaunay-Belleville changes comprise the inclining of the valves in order to diminish the size of the combustion chamber. This has been done on all the models but a small four cylinder car. Gate change has had to be adopted to meet the requirements of the British market. An interesting feature is the new carbureter, which really consists of two carbureters combined,



Side and transverse sectional views of the 15-horsepower Panhard-Knight motor

one being an ordinary single jet type with variable primary intake and additional air through a glycerine dashpot, and the other a surface carbureter, with the same level maintained as in the float chamber, and used for slow running and starting.

The Rotary Valve Itala Motor

An examination of the new valve gear introduced by the Itala Company, one of the famous Turin firms, shows the rotary valve therein adopted as something quite different from any of the other few types of rotary valves on the market. Only the 35 horsepower chassis has been fitted with this new device. The engine has four vertical cylinders, which are cast in pairs. The bore of the cylinders is 105 mm and the stroke 150 mm. The ordinary four inlet and exhaust valve spaces in the poppet valve type of engine are replaced by two spaces, each containing a rotating valve that carries out the functions of distribution.

This rotating valve is of the simple design and is connected by a vertical rod to one shaft that takes the place of the two camshafts. The function of this shaft is to drive the magneto and water pump, and to rotate the valves. This is done by means of an endless screw of the same type as the well-known Itala device, which for years has proved so efficient for driving the firing cams of the low tension ignition.

Each rotating valve exercises the same functions as two inlet and two exhaust valves. The ordinary water and oil circulations for cooling and lubricating the engine are extended to the rotary valve; and when it is remembered that the valve rotates only once to four revolutions of the engine, it can be seen that the chances of seizing are eliminated. Should, however, seizing take place through the unlikely event of both cooling and lubricating systems not functioning properly, a wedge inserted in the vertical rod which rotates the valve would act as a safety valve and sever the connection, and thus prevent any damage to the engine. In order to insure regular and even functioning of the rotary valve there are two compensating chambers in the wall of the valve cylinder so that all pressure on the rotary valve by the explosions is obviated. By the system of intake and exhaust, the only alternating moving parts in the whole engine are the pistons, and consequently this type of engine can be constructed to run at high speeds without provoking vibrations. As the rotating valve, which is on one side of the cylinders, rotates almost in contact with the combustion chamber (which is made perfectly semi-spherical), and there is no valve space on the other side of the cylinders, the efficiency of the engine in the production of power from a given cylinder volume has been found to be increased by about 30 per cent.

Few Cars, with Power Tire Pumps

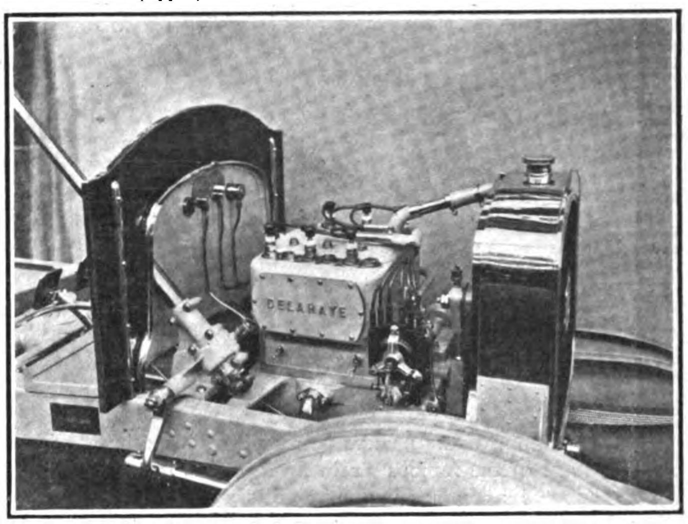
One of the few cars shown with a power tire pump is the new six-cylinder Armstrong-Whitworth of 90 by 135 mm. bore and stroke. In addition to the pump, provision has been made for electric lighting by dynamo. On the valve side of the motor there is an auxiliary shaft driven off the enclosed timing gears and connected up to a lighting dynamo mounted on the bed plate of the motor. On this auxiliary shaft is carried a pinion transmitting power to a parallel shaft operating an air-cooled cylinder for pumping tires, there being a sliding pinion on the pump shaft which can be brought into engagement with the fixed pinion on the dynamo shaft.

Scat, Piccard-Pictet, and Adams are the only other firms fitting a tire power pump. The Piccard-Pictet case is particularly neat, the pump being a single vertical cylinder bolted to the top of the gearbox cover and having its piston worked off one of the constant meshing pinions. This pump has been employed for a couple of years on both the Piccard-Pictet and the Hispana-Suiza cars. Piccard-Pictet also shows a new rear axle in a one-piece forging, having very much in common with the axle shown by Renault a year ago. It is a one-piece production with the ends bored out to receive the drive shafts and the center forming a cradle for the differential, the front being closed by a steel plate, and the rear by an aluminum cover. A convenient fitting is a combined ignition switch and petrol cock on the dashboard. The gasoline is under pressure, the feed pipe passing across the front of the dash and the cock connected to the switch, so that when the ignition is off the gasoline flow is closed.

Side Lights on the Henriot Motor

The Henriot rotary valve motor has four cylinders of 95 by 140 mm (3.7 by 5.5-inch) bore and stroke. On one side of the cylinder casting and near the head—in this case on the left-hand side—is a cylindrical chamber receiving the hollow rotary distributor. The rotary valve chamber has three sets of ports: in the head the intake ports giving communication with the intake manifold surrounding the chamber; below, in the same vertical plane, the exhaust ports admitting into the bolted-on exhaust manifold, and between the two the port communicating with the combustion chamber. The hollow rotary distributor has four roughly D-shaped sections to correspond with the ports for the four cylinders, and it is by reason of the flat portions of the roller that the opening into the cylinder can be put into communication with either the intake or the exhaust ports, while the circular portion of the roller shuts off all communication with the combustion chamber during compression and firing. The most important feature of this motor is that the ports are covered by the piston at the end of the compression and at the beginning of the firing strokes.

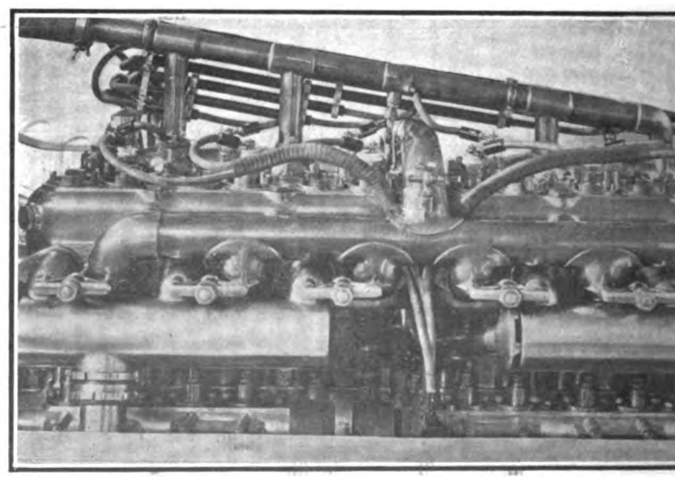
In order to allow the easy passage of the piston across the face of the ports, these latter are two in number and oblong



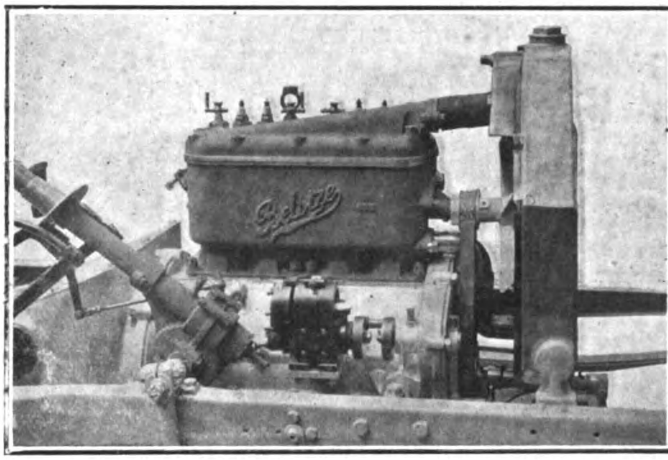
Delahaye six-cylinder monobloc V-type engine

shaped, the greatest dimension being in the direction of travel of the piston. The two ports in the distributor chamber are also oblong shaped, but with the greatest dimension in the opposite direction—from front to rear.

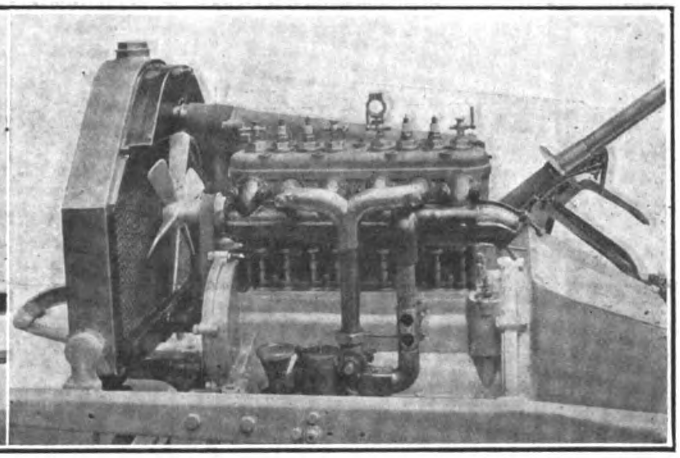
The motor is a bloc casting with the intake manifold cast with the cylinders, and with the distributor water-jacketed. Water circulation is by thermo-syphon with the inlet pipe connected up to the right-hand side of the motor and the outlet from the top of the casing to the dashboard radiator. The crankshaft is carried on three plain bearings, and the crankchamber is divided



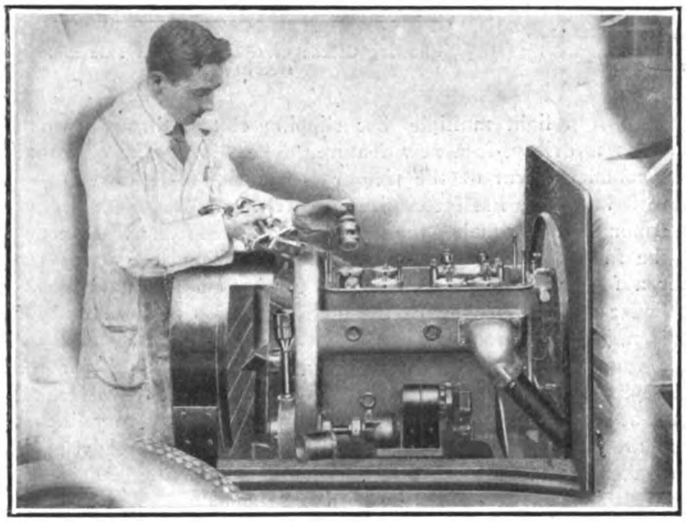
Left side of Rolls-Royce engine



Magneto side of Belsize 10 12 motor



Valve side of Belsize 10-12 motor

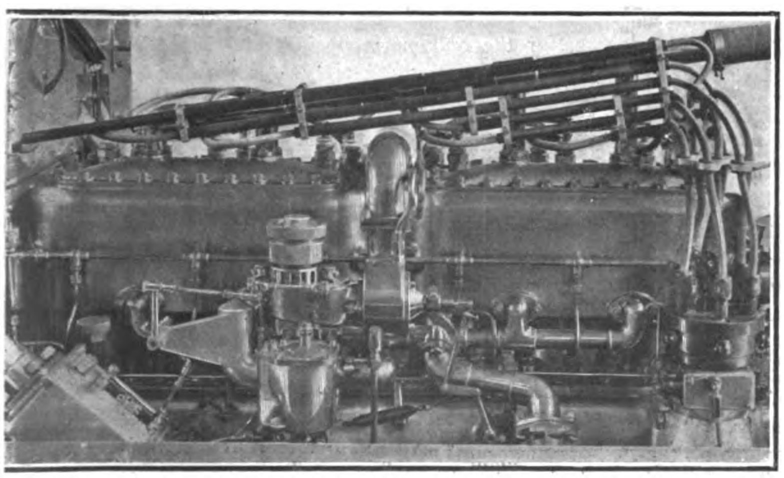


Showing easy removal of valves of Germain motor

into two chambers to secure the correct level of oil in each for splash lubrication. The lubricator is mounted high up on the dash and driven by belt from the rear of the distributor. What is generally known as the Renault type of bonnet has been adopted, but combined with it is a 10-gallon gasoline tank, and in the center of the dash the belt-driven mechanical lubricator already mentioned. There is no fan, and no vanes on the flywheel.

Innovations of the Rolls-Royce

Rolls-Royce, Ltd., exhibited three complete cars which, so far as their outward appearance was concerned, showed no change from last year's models. A number of detailed improvements have been effected, however. Carburetion has been given special attention in the new models, and the flywheel and timing gears are so connected to their shafts that any slight vibration at certain motor speeds has been eliminated. Because no chassis was shown, it was impossible to get any detailed information as to the improvements which have been effected.



Right side of Rolls-Royce engine

The 40-50-horsepower model has six cylinders, cast in blocks of three. The valves are all on one side and are operated by rocking levers. The motor, which has a seven-bearing crankshaft, is specially suspended by links. There appears to be little change in the design and arrangement of the power plant, though several refinements are evidenced. The three-speed drive is retained, which is contrary to the adoption by some of the other prominent makers of the four-speed type. One important innovation for 1912 is the adoption of a spherically ended torque tube which encloses the propeller shaft. The frame has been made more rigid also, by the addition of tubular cross-members throughout, with the exception of the rear tie-rod, which is of U-section.

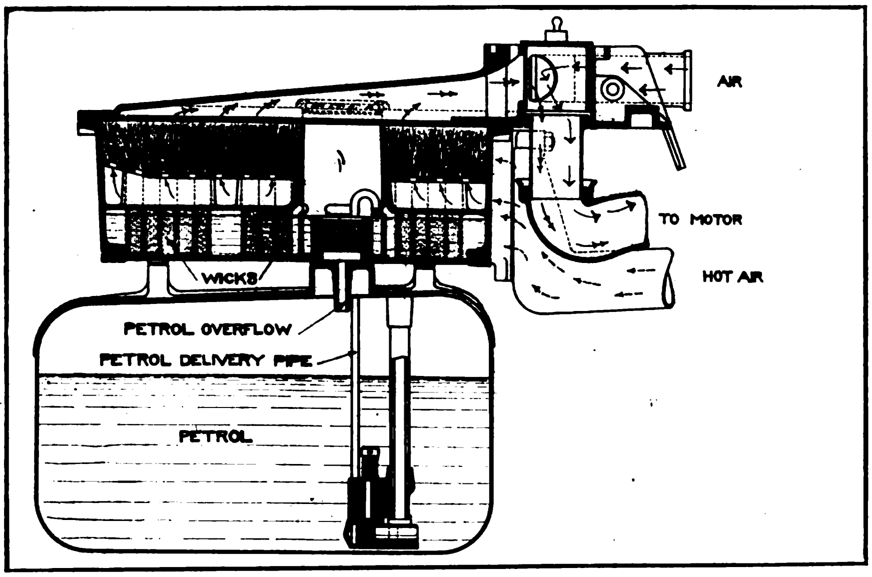
Lancia Abandons Fan Belt-Drive

On a small four-cylinder monobloc Lancia, the designer has got away from the use of belt drive for the fan by fitting a water turbine within the fore end of the water jacket. The car being a new one, only just received from the factory, no detailed information could be furnished even by the agent; the external appearance, however, was remarkably neat, there being nothing outside to show how the fan was driven. Lubrication is under pressure to the two ball bearings in which the crankshaft is carried, and to the connecting rod ends, but no pump was visible; it was declared that the half time pinion acted as oil pump, but how the agent was unable or unwilling to say. On this car the four-speed gearbox is now carried on the rear axle, with all the gear shifting mechanism—selective type—passing inside the torque tube. The bigger car, four cylinders of 100 by 130 mm., was orthodox in the position of its gearbox, but original by being a one-piece casting with the motor base, two arms at the extreme rear of the box attaching it to the frame members.

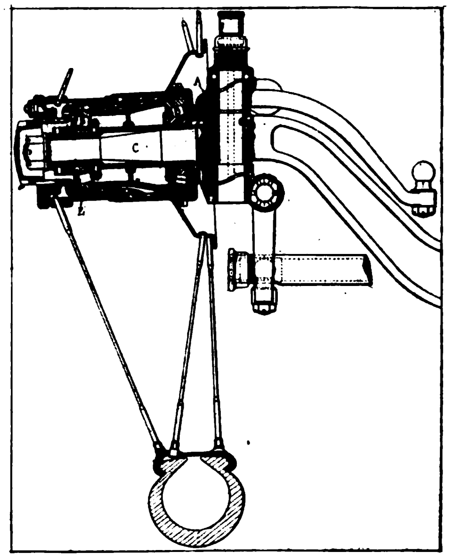
To facilitate brake adjustment the Vulcan cars had an extension from the winged nut regulating the external shoes of the transmission brake, up to the side member of the frame; instead of having to stoop under the chassis to regulate these shoes, the work could be done from the side of the car.

Lanchester Cars Present Novel Features

Despite the fact that conservative design finds favor among English engineers, there is one British car which stands out distinctively—the Lanchester. There are many novel features possessed by the Lanchester—such as the wick carbureter, the



Wick carbureter, one of the novel features of the 1912 Lanchester line



Showing details of Crossley front axle and steering knuckle

epicyclic gearing and principally in the absence of a front bonnet.

In 1912, two types of Lanchester cars will be constructed, the 25 four and the 38 six, both having pair-cast cylinders of 4-inch bore and stroke. This is about the only case of a "square" European engine; the 1912 average will be somewhere about a 1.6 ratio of stroke to bore.

Prominent features of the Lanchester motor are the horizontally placed valves in the heads, these valves being kept on their seatings by flat springs. On the "four," thermo-syphon cooling is quite satisfactory; the bigger six calls for a pump. High tension dual magneto and high pressure (30 pounds square inch) lubrication are employed. The main fuel tank forms one of the cross-members of the frame; from here the liquid is pumped up by the engine to the wick chamber, through which the inrushing air is passed. Extra air is provided through an automatic valve, and the outfit is complete, save for an adjustment left to the driver to compensate for weather variations. By the fact that the supply of fuel pumped up to the wick-chamber varies directly with the engine speed, the strength of the mixture is always approximately constant.

The transmission system comprises a multiple disc clutch and three-speed epicyclic gearbox, the gear changes here being made by means of disc clutches, with a positive lock for the high. In the gearbox there is a force pump which supplies oil under pressure to all the bearings. Final transmission is by worm gearing, with the worm below the center.

The rear suspension is another novel point. Two long flat springs are attached to the frame sides and their rear ends are free to slide in block brackets on the axle casing. An arrangement of parallel and jointed radius rods keeps the axle in place.

Some Daimler Refinements of Detail

While Daimler, of Coventry, has made no great change in the Knight-engined models, there are a few interesting detail improvements. On the six-cylinder models provision is made for receiving a dynamo for electric lighting purposes. It is evident that this matter will receive more and more attention from car manufacturers, for the numerous electric lighting systems now on the market are meeting with a considerable amount of favor, but the great difficulty is that they cannot be neatly and conveniently fitted when produced as an afterthought. A change over has been made in the positions of the sliding and universal joints, the sliding joint now being at the rear of the propeller shaft, instead of at the fore end. Among the few changes in the motor is the attachment of the sliding oil troughs to the upper portion of the crank chamber, the lower portion thus acting as an oil retainer only. A patented vibration damper, consisting of a light multiple disc slipping clutch, through which the fan is driven, is a new feature. The slip on the clutch at the commencement of the tremor is sufficient to rectify it before it has made itself conspicuously felt.

Among English makes the highest ratios of stroke to bore are to be found on Sunbeam cars, where dimensions are 80 by 150 for a four-cylinder, and 90 by 160 for both a four and a six-cylinder model. In view of the high reputation of Sunbeam for design, it is interesting to note that five bearings are used for the four-cylinder monobloc motor and seven bearings for the six-cylinder with its cylinders in two castings. The valves, all on one side, have their stems inclined with a view to reducing the area of the combustion chamber. This, as already mentioned, has also been adopted by Delaunay-Belleville. Webs between the hangers and at the front of the motor completely fill up the space between motor and frame.

Unit Construction Used in La Buire Cars

The novelty of the La Buire construction is the fitting of a foot and lever operated brake on an extension of the propeller shaft at the back of the axle. This firm has also made use of unit construction for all models and has some of the largest monobloc castings to be found in the show, a six-cylinder being 85 by 140 mm., and the biggest fours in one bloc being 90 by 160 and 105 by 150 mm. respectively. There is a special coupling on the tail shaft of these models, allowing them to be quickly disconnected from the propeller shaft, enabling the multiple disc clutch to be withdrawn in a single unit.

Self-starters do not appear to have been very seriously tackled by European makers, for the only new one is to be found on the Alldays car. It consists of a small air compressor driven by gearing from the chain-driven camshaft and compressing air into a tank. The compressed air is used to drive an oscillating pneumatic motor connected up by worm gearing to the clutch shaft, with an arrangement by which the clutch shaft can overrun the shaft of the pneumatic motor. Compressed air and other types of self starters were brought out in Europe four years ago, but owing to their complications never really caught on. Where they are most desired is on small cars driven by their owners, and it is here that complication is least needed.

Vauxhall Typical British Poppet Valve Car

Two types of the Vauxhall car are made, the 20 and 30 horsepower, with four- and six-cylinder engines respectively. The casting of the 30-horsepower cylinders in threes is the method followed by the majority of British constructors. No case exists of the use of single-cylinder units for a six. The bore and stroke dimensions are 90 mm and 120 mm respectively, this ratio being somewhat less than the average. Special pains have been taken to secure minimum weight for the reciprocating parts. The sides of the cast-iron piston are drilled out, while the connecting rods are drilled away till the finished article looks quite fragile, but no case is reported of failure at this point. The result of the weight-cutting is apparent in the increased speed of rotation—very little vibration being observable at high speeds.

It will be noted that the valves are all on one side and that the tappets are cased in by removable plates. All clearances in the valve mechanism are cut down, six-thousandths being the gauge limit between tappet and valve. The valve camshaft, the magneto shaft, and even the fan spindle, are all driven by means of silent chains. Thus there is no gear wheel inside the engine save the internal magneto distributor wheels.

In the transmission system, a multiple disc clutch, with 45 flat plates of phosphor bronze and mild steel, takes the power to the four-speed gearbox. In the Vauxhall the top gear is the direct drive. The gearbox is quite ordinary, shortness of the shaft being obtained by the now general practice of sliding the third speed gear inside the constant-mesh wheel to give fourth speed. The locking of the gear which is in use is made by spring plungers placed in the top of the case; the change speed lever and gate are quite free of all adornment, a noteworthy point being, however, that the transverse change-gear rod is provided with a double universal joint to compensate for any frame flexure on rough roads. The rear axle is bevel driven, rather the exception than the rule in these days of worm drive. To take up the drive a deep pressed steel girder is provided as a torque stay.

Both sets of brakes are internal expanding, the shoes being lined with copper and the drums provided with heat-dissipating flanges. The foot-operated brake is placed behind the gearbox.

As to Meeting American Competition

Very few attempts also appear to have been made by European manufacturers to meet American competition in the cheap car line. In most cases it is declared that quality will win out, and that in a couple of years the demand for American cars will have ceased. Beloize is about the only maker having seriously tackled the problem, the result being a complete two-seater with hood, windscreen and lamps selling at $1,100. The motor is a four-cylinder of 69 by 130 mm. bore and stroke with unit construction, its general design being European throughout. Another example is the B. S. A. car with a four-cylinder Knight motor. The power plant, which is 75 by 114 mm. bore and stroke has been built by the Daimler Company and has really nothing distinguishing it from other models. The chassis, produced at the Birmingham Small Arms factory, is a direct copy of a well-known American car, with the difference that the three-speed gearbox is incorporated with the rear axle, and has its gears operated on the selective principle. As a complete two-seater it is being sold at $1,550, a price which is much higher than the Beloize and greater than many American cars now on the European market.

Résumé of the Prospects for 1912

The British Industry has the immense advantage of being united in a self-governing body—the Society of Motor Manufacturers and Traders—and therefore, it is a simple matter for a generally expressed wish to pass gradually into law. Hence, next year may see the abandonment of the system whereby cars are labeled by their year of origin.

The past year has been extremely successful on the whole. A few concerns have not found orders rise to the high water level of the previous year; in these cases, it is evident that the popular taste has not been accurately gauged. The majority of the manufacturing firms report that business has shown an appreciable and welcome advance on the last report.

The state of trade may be fairly well judged by reference to the cheap car trade. The class "below $1,600" has received very meager attention from the high-grade British maker; it would be correct to say that it has been almost entirely ignored. But it has always been clear that this section offered a very extensive field of business, in which largeness of output would compensate for smaller margin of profits; and the manufacturers have not been blind to the fact. Therefore, it has been an open secret that the leaders have designed and constructed cars which may be classed as 12 horsepower, four-cycle, four seaters at $1,200.

It is sufficiently clear, however, that these cars are not going to figure on the 1912 programs. The state of trade is taken to indicate that enough business will be available in the above $2,000 class to keep the factories running, and meanwhile the smaller man can wait another year.

This is just where the American maker will probably score. The smaller man is quite tired of waiting; the various American cars now on the British market have sufficiently well demonstrated their good points to have overcome the former inherent prejudice, and reasonable success lies clear ahead.

At present, there are a dozen American makes available for the British buyer; some, as the White, Cadillac and Ford, have been on the market for years; others, as exampled by the E-M-F. Flanders, Hudson, Brush, are of more recent introduction. Anyway, no matter what make be selected, the general reports agree that the cars have given reasonable satisfaction to their purchasers—more than this, they have proved themselves capable of better average performances than British cars of equal power but higher price. The anti-American car prejudice is now almost completely lived down. Next year should therefore prove successful to the American agencies in Great Britain.

To return to the British makers, it seems that the average power, in place of being reduced, will show an appreciable increase next year. This is due to the introduction of 20-horsepower models (with the corresponding 30-horsepower six-cylinder car) by firms which have previously concentrated on, among other types, the immensely popular 15.9 (80 millimeter bore). This car has proved highly efficient; the result has been that it is always overloaded and worked to death.

The average buyer is too unintelligent to be trusted with a light and efficient production; he keeps the engine extended to its limit all the day and wrecks it within a year. Hence the return to 20 horsepower (90 millimeter bore) for average touring and for small covered body cars. The smaller 15.9 will still be popular, but buyers will be strictly cautioned as to its limitations.

Increased attention is being paid each year to the design and quality of the coach work. The work turned out by the leading car firms is lighter in weight and better in quality than from the best of the old established coach builders, and almost all buyers now purchase the car complete. This is quite a change from a few years ago, when about half of the manufacturers' output consisted of chassis, upon which bodies were fitted by other firms.

Outstanding Features of Olympia Show

Four new sleeve or slide-valve motors; Darracq with single rotary distributor; Argyll and Piccard-Pictet with single sleeve; Itala with rotary distributer on vertical axis, one distributer operating two cylinders.

Increased use of the Knight motor.

Increase of bloc castings. Practically all four-cylinder motors up to 4 inches bore in one casting; a number of sixes in a single casting; intake and exhaust manifolds generally cast with cylinders; webs between crankcase hangers allowing mud pan to be abolished.

Unit construction of motor, clutch and gearbox, generally with three-point suspension. Where unit construction is not adopted three-point suspension is generally used for motor or gearbox or both.

Chain-driven cam and magneto shafts on a very large number of models.

Lengthening of piston stroke, the average ratio to bore on medium-sized motors being 1.63 to 1. A few as high as 2 to 1.

Speed Practice Opens for Forty-Two

SAVANNAH, GA., Nov. 20 (Special telegram)—Jay McNay, driver of a Case car, was killed to-day in the first official practice and his mechanic, M. F. Maxwell, was seriously hurt. Maxwell is now in the local hospital. Joe Dawson, driver of one of the Marmons, also lies in the hospital. He was hurt in a collision while trying to avoid hitting a touring car. The accident to McNay has saddened the practice now being held. Maxwell, his mechanic, who was able to talk this afternoon, states the reason for the accident: "Just before arriving at the cattle-park the flagman gave us the clear flag, and of course we put on more speed. Just then we saw a wagon in the road, and, as McNay swung to one side, the car skidded into a tree." McNay's chest was crushed by the steering wheel. Death was instantaneous. Maxwell has his arm broken in three places, his left side bruised and his face lacerated.

The accident to Dawson was unusual. He was riding as mechanic for Joe Nikrent and had just changed seats with him. Approaching Bethesda on Whitefield avenue the road is a little narrow and here they met a touring car. Nikrent took the side of the road with too much speed and Dawson was thrown out. He was unconscious until he arrived at the hospital.

Knipper, in a Mercer, was following close behind Dawson and Nikrent. He set his brakes and came to a sudden stop. Barnes, following in a second Mercer, failed to see Knipper when he made his sudden stop and the two went together. Both cars were badly broken up but none of the occupants was hurt.

De Palma, who made the two fastest laps in the Grand Prix in 1908, drove one lap at the rate of 75.9 miles an hour in his Mercedes. Of the smaller cars, the Mercer driven by Barnes made the fastest time—66 miles an hour. Summary:

Car	Driver	Lap time	Fastest time M.P.H.
Fiat	Bragg	15:50. 15:09.1 23:49.3	67.5
Fiat	Matson	20:17.2 36:17. 14:38.2	70
		15:09.2 16:15.1	
Benz	Bergdoll	15:41.3 13:47.4 13:54.1	74.8

Mercer	Hughes	15:47. 13:36.2 15:20	77
Abbott-Detroit	Mitchell	16:26.4	63.3

Under the present plan the course will be open to the exclusive use of the drivers in each of the classes at specified times. The small cars will be allowed to practice at speed for 1 hour before noon each day, while the Vanderbilt Cup cars and Grand Prize contestants will come on the scene later in the day.

The Savannah Challenge trophy and Tiedeman Cup races will be called at 7 o'clock next Monday morning. The first event is thirteen laps of the 17.14-mile course, or 222.82 miles. The Tiedeman is ten laps of the circuit, or 171.4 miles. The two races will be run together. It has been estimated that the speed achieved in the Savannah Cup race will approximate 62 or 63 miles an hour. If that proves to be accurate, the race will be finished at about 11 o'clock. Several of the contesting cars named in this event have shown speed in excess of the figures given.

The difference in mileage between the Savannah and Tiedeman races will probably cause the smaller cars to complete their race considerably before the Savannah cars finish.

It is planned to start the Vanderbilt Cup race about 11.30 o'clock. This race consists of seventeen laps of the course or 291.38 miles. If a speed a trifle in excess of 70 miles an hour is made, the race will be over at 3.30.

It is quite likely that the Grand Prize cars will be sent away early in the morning of Thanksgiving Day. The exact hour has not been fixed for the start, but it will surely be before 8 o'clock. The distance of the Grand Prize race is twenty-four laps of the course or 411.36. Traveling at the rate of 75 miles an hour the winner cannot finish the distance under 5.15. If the start is at 8 o'clock, this would bring the finish to 1.15 p. m.

The Marmon drivers seem to have a strenuous time ahead of them as Dawson and Patschke are scheduled to start with a pair of small cars in the Savannah Challenge Cup race at 7 o'clock Monday morning. As soon as this contest is finished the pair will assume the handling of two big Marmons in the Vanderbilt Cup race and on Thursday both will drive in the Grand Prize. Hughes, captain of the Mercer team will have his hands

GRAND PRIZE—24 LAPS—411.36 MILES—NO LIMIT TO DISPLACEMENT

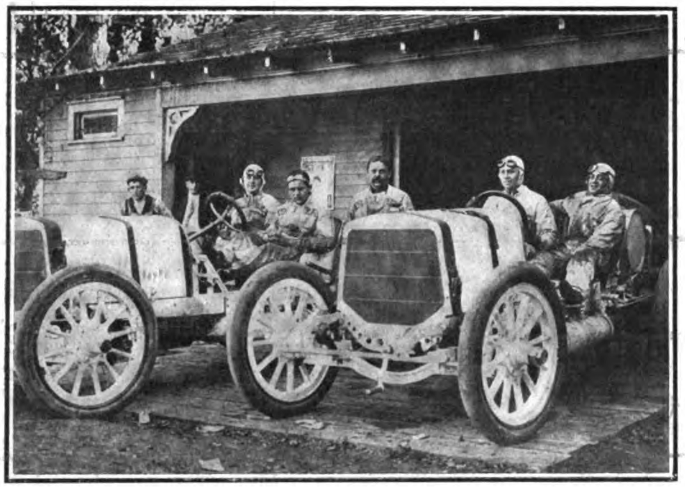
View of the upper end of the stretch, showing grand stand and pits—Hearne in Benz finishing his fast practice lap



Where the Lozier team is camping during practice week

full on Monday when he is scheduled to drive a small car in the Savannah and the new Mercer six-cylinder car in the Vanderbilt.

Bruce-Brown will drive a Fiat in both Vanderbilt Cup and Grand Prize races; Mulford will drive a Lozier in both; Limberg and Mitchell will handle Abbott-Detroits in both big events; Disbrow will drive the Pope Special in both. Harry Cobe is the only driver who will handle two cars of different makes at the meeting, driving a Buick in the Grand Prize and a Jackson in the Vanderbilt. All the other pilots have but a single mount.

The fields, from present indications, will not be large. The total official entry list for the four events to date comprises only forty-two cars, a reduction of twelve from the estimated entry list of last week. The box is still open and other entries may be made officially until Wednesday midnight, but it has been unofficially announced that if anyone wants to go in any of the races he can make legal entry on Friday.

Referee Morell made a circuit of the course this morning and pronounced it better than ever before as the result of the radical improvement upon it in preparation for the races.

On Saturday night a meeting of the drivers and mechanics was held at which preliminary instructions to cover practice were given out.

It is believed that the plan adopted to run the light car races before the Vanderbilt Cup will result in better time in each of the three races. In such contests the presence of mixed classes always has a tendency to develop slower time, particularly in passing on the turns. If all the cars engaged have approximately equal maximum speed, there is less likelihood of delays. The effect will be not only to make the races faster, but it is expected to make them safer as well.

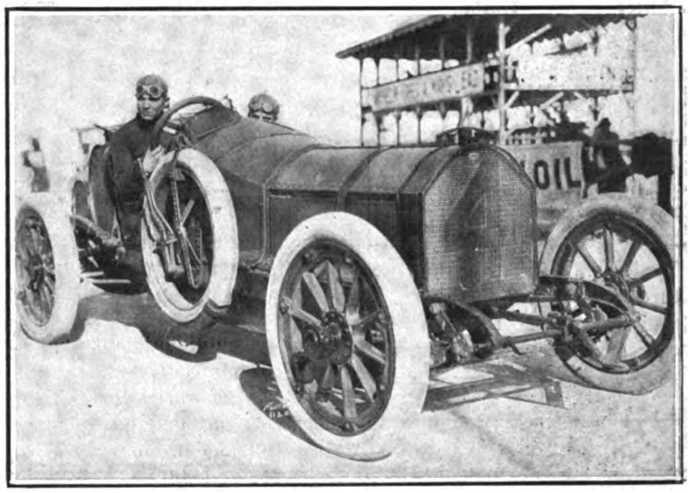
The reason underlying the action of the committee in separating the light classes from the Vanderbilt was the well-known ability of some of the drivers engaged in these contests to make the slower car win. This of course may be accomplished legitimately by good jockeying in case the contest developed a tight fit. If a car, slightly slower than a rival automobile, is in the lead and the pilot drives desperately upon approaching a turn, it may be possible for him to get away so far that the pursuing car not not catch him until the next turn, where the process may be repeated. In this way a narrow margin of advantage may prove enough to win or gain prominent place for a car that is not quite equal in speed to some of the others that finish behind it.

Another reason for this action, and the one that is most generally emphasized, is that drivers engaged to drive in the light car events and the Vanderbilt Cup, could not do so if the races were run coincidentally. The city is rapidly filling up with visitors and big crowds are out to witness the speed practice each morning. A rule has been promulgated barring women from the racing cars in practice and prohibiting drivers from moving in the reverse direction of the course.

In the Grand Prix there is no limit to the piston displacement. The Vanderbilt Cup, however, provides for a piston displacement of 301 to 450 cubic inches; the Savannah Challenge Trophy for cars of 231-300 inches piston displacement, and the Tiedeman Trophy for cars of 161 to 230 cubic inches displacement inclusive.

Of the forty-two cars entered there are fourteen machines in the Grand Prize, the same number in the Vanderbilt; six in the Tiedeman Trophy and eight in the Savannah Challenge Trophy event.

Over $20,000 has been spent on the course and over $5,000 on the home-stretch alone. All turns have been banked and the course widened to 40 and 50 feet. At other places the course has been cut through a forest, thereby cutting out several bad turns



Dawson in the Marmon—hurt during a morning tryout

which bothered the big cars very much last year. The home stretch is almost like a boulevard, especially that section between Dale avenue and Waters road which was unbanked last year, and until passing the general admission grand stand, a quarter of a mile from the turn. The course has been widened here to over 40 feet.

New arrangements have been made to enable spectators to get to the grand stand. Instead of having to walk from the car line for a quarter of a mile, a new belt line has been built up to the stand on which cars will be run every 30 seconds.

The course will be guarded by the militia of Savannah. Around the stand and in the city limits the police will look after things.

The prices this year are: For the grandstand $3 for two days; for the admission stand, $1 each day. Boxes for two days, $50 and parking spaces, $25. Because of the unexpected rush for boxes, ten additional ones had to be made. The grandstand has been improved by boarding up the back. Last year the wind blew under it and made it very disagreeable for the spectators. The press stand and official judges' stand have all been repaired and are now in first-class condition.

Prize List Largest in the Country

The prizes this year are probably larger than any ever offered for racing events in this country. All told, there is over $30,000 to be given the winners of first, second and third places in the four events. The cash offer of *The Savannah Automobile* of $12,500 will be divided for the four events, while the Rayfield Carbureter Company has offered $2,500; the Remy Magneto Company, $4,250, and the Bosch Magneto Company, $1,400. The Monogram Oil Company and other manufacturers have announced that they will give prizes if their goods are used on the winning machine. The cash prizes will no doubt run as high as $40,000 before the races are over.

A prominent Savannah man, who gave $1,000 last year for the first American car finishing the race, has announced that he will give $1,000 this year, but this time it must be an American car winning the race and not the first one to finish.

A large canvas tent will be placed in the Park Extension, the soldiers' parade-ground to accommodate the many cars that will be here during the week.

The hotels are rapidly filling up but still have rooms left. The homes of the people in the city have been thrown open just as was done last year and room for over 30,000 visitors is available.

During the days when there will be no racing a football game between Georgia Tech. and Auburn will take place. There will also be an aviation meet, with several of Curtiss' best men. Those in charge of this event are trying to get up a match between one of the aircraft and a Benz or Fiat racing machine.

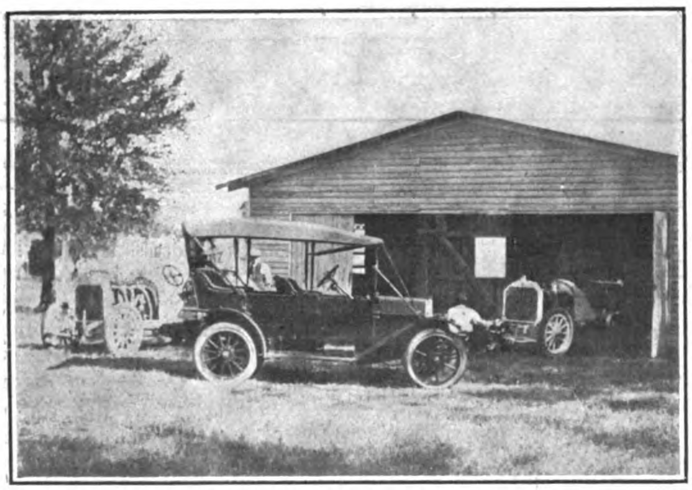
Racing Circuit Planned in Middle West

SIOUX CITY, Nov. 20—At a meeting of the Sioux City Automobile Club last week it was decided to push all improvements on the new speedway to be constructed here and have them completed by July 1. The committee was instructed to obtain estimates on grading for a saucer-shaped mile track, on an 8-foot grade and on a 12-foot grade, and also for an oblong track with grades on the curves of 8 feet and 12 feet. Among other improvements a club house will be built at the speedway.

George O. Jamesson resigned as president of the club as he moved to Des Moines to take the State agency for the Apperson and Reo automobiles. C. S. Douglas of the Nebraska Buick Automobile Company was elected to succeed him. F. H. Reid was elected secretary to fill a vacancy caused by the resignation of C. S. Douglas.

H. B. Groves becomes the manager of the Interstate Auto & Supply Company which position Mr. Jamesson held.

There is some talk here of promoting a circuit of automobile



Visitors at the Benz camp at a farmhouse alongside the course

races taking in Omaha, Lincoln, Sioux Falls and Sioux City. Omaha, Sioux Falls and Sioux City held successful race meets during the past season and are improving their speedways, and it is thought that if the four cities mentioned should go into a circuit the manufacturers would send some of the fastest cars in the country to participate in the races.

Jersey Motorists Join for Good Law

New Jersey automobilists are now a unit in favor of a new, moderate, sensible automobile law. The recent election changed the complexion of the legislature of New Jersey to such an extent that much hope for better things is springing up in the hearts of the automobile fraternity.

As an indication of concerted action and solid ranks among the motorists the fact has become known that the New Jersey Automobile and Motor Club, the large organization that split away from the American Automobile Association and the Associated Automobile Club of New Jersey last year, has made advances to the Associated Clubs and the New Jersey Automobile Trade Association to join hands with it in drafting a new automobile law for presentation to the coming session of the legislature.

With this idea in view the New Jersey club, the Associated Clubs and the Trade Association have formed a committee of fifteen, five from each organization, and empowered the committee to act. The committee has been instructed to draw up a bill repealing the noxious power-of-attorney clause in the present law, by which visiting automobilists are obliged to sign instruments empowering the Secretary of State of New Jersey to accept service for them in case of alleged infringements of the Motor Vehicle law. The bill will also be framed to provide for a reasonable exemption of visiting automobilists.

The measure advocated by the trade body and the association of clubs, which was built on the lines suggested above, was defeated by a single vote in the upper house after being passed by the assembly. The composition of the Senate remains almost the same as it was before, but the Assembly has been radically changed.

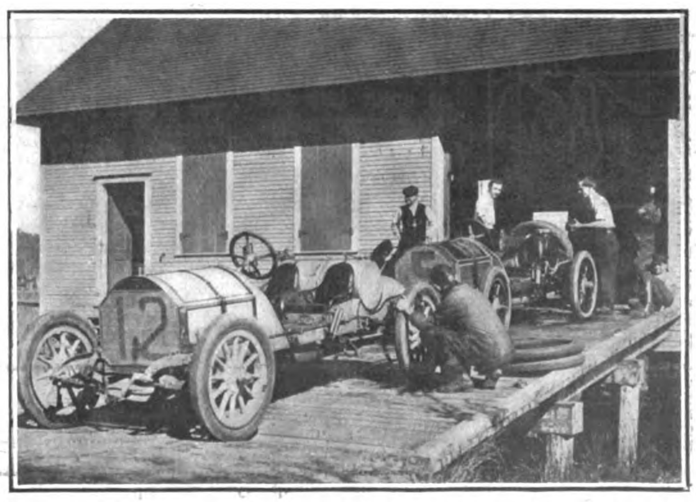
Legal Matters That Interest Motordom

Three legal matters of importance to the automobile industry are being considered in the courts at New York at this time. Another preliminary injunction has been granted by the federal court in one of the Weed chain cases. This is similar to a host of other proceedings based upon the same subject matter. The defendant in this case was the Seneca Chain Company.

The second matter is the pendency of the decision of Judge Hazel in the suit of the Republic Rubber Company vs. Morgan and Wright, involving an alleged infringement of the knobby tread patent. The third interesting case is the suit of Fletcher R. Williams vs. the Lozier Motor Company, based upon an alleged agreement to sell the control of that company. This matter will be heard by Justice Seabury in part 1 of the Supreme Court on Thursday.

Delaware Club Holds Annual Banquet

WILMINGTON, DEL., Nov. 20—The annual banquet of the Delaware Automobile Association, which was held Friday night at the Clayton House, in this city, was a notable event. About 100 persons were present, mostly members, though there were a few guests, including Robert P. Hooper, president of A. A. A.; H. M. Rowe, president of the Maryland Automobile Association, and Powell Evans, president of the Automobile Club of Philadelphia.



The tuning-up process at the Mercer camp keeps all hands busy

Automobile Metallurgy Made Easy

By E. F. Lake

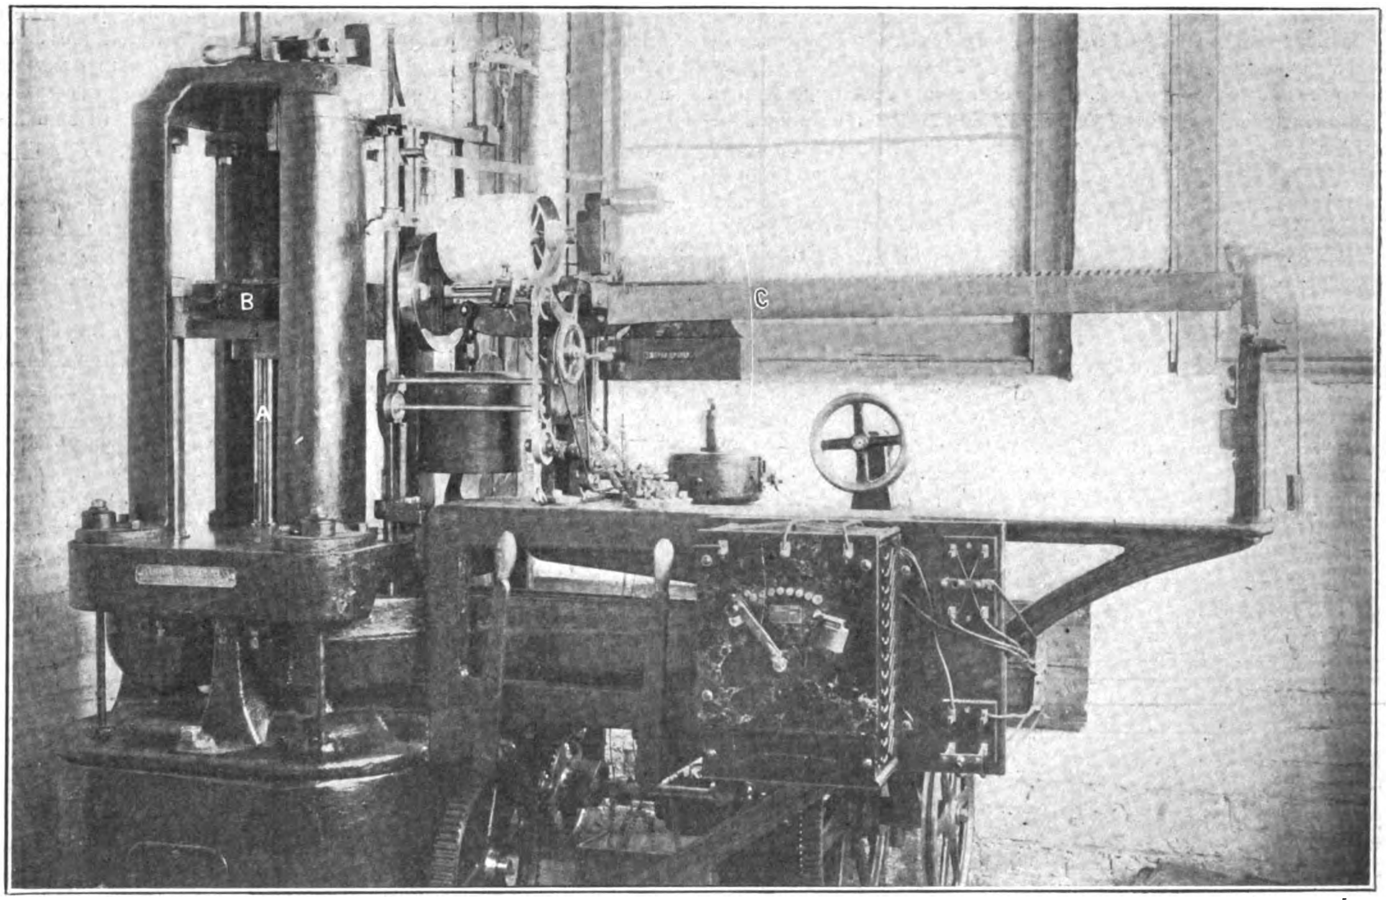


Fig. 1—Type of machine used to determine the tensile strength of metals

Part I.--Tensile Strength

TENSILE strength is a term frequently used by engineers and designers of automobiles, as well as by those who are manufacturing the metals for, or into, the numerous parts that enter into the construction of a motor car. The term is so familiar to them, they never think that the buyer or user of a car is nearly always one whose line of work, or energies, has carried him into other fields in which he seldom hears these words and thus has no occasion to know their meaning. Even many of those who sell cars do not always know the meaning of the term. It is therefore well to start at the beginning and define its meaning, as well as show how important it is in the selection of materials for the car's construction, or in deciding on the size and shape of the parts. It is a term that should be thoroughly understood.

Announcement

In this issue THE AUTOMOBILE begins a series of articles under the title "Metallurgy Made Easy." This series will continue from week to week and will cover the entire gamut of metals as applied to the automobile. The aim of the series is to familiarize the lay reader with the terms used in metallurgy as well as the different metals, their strengths, uses, etc. The articles are written in language to suit the beginner, the man who has heard of tensile strength, elastic limit, reduction of area and the many other terms. The series will take up in elementary form the different metals which enter into the construction of the automobile, including Bessemer steel, open-hearth steel, electric furnace steel and the many other steels. Readers desiring additional information on the subjects treated in the different articles are requested to write to the Editor and questions will be answered and discussions solicited.

Next week, elastic limit will be the subject.

In selecting the different metals that make many of the parts of a complete automobile one of the most important things to know is the tensile strength of each kind. To obtain this, samples or test bars of each kind are prepared and these placed in a tensile machine similar to the one shown in Fig. 1.

The test bar is first clamped at both ends and pulled apart when the machine is started. The part B, which grips the upper part of the test bar, is then gradually raised by a screw and this stretches the test bar until it breaks. The number of pounds that are required to break this test bar is shown on the scale at C and this is known as the tensile strength. In order to standardize this so it can be compared with all bars tested, it is computed in the pounds required to break one square inch of the surface across the part where the bar is broken.

The test bars are usually made of a definite size before they are broken so that the pounds per square inch can easily be computed and thus made reliable. In Fig. 2 there is shown the standard shapes that have been adopted for both the steel and cast iron test bar. D is the steel test bar, which is threaded on both ends and has a standardized length between the threaded portions, as well as a standardized diameter. It is screwed into dies that are supplied with the machine and these are held in place by wedges that are also a part of the machine. Test bars that are not threaded may be gripped with the device that holds the cast-iron test piece. Thus square, hexagon, octagon and other shapes may be tested. The diameter of these bars in the center where the break occurs is 0.505 inch and this gives an area of 1-5 square inch. The reading obtained from the scale at C is thus multiplied by five, in order to obtain the tensile strength per square inch.

When it is understood that the tensile strength of the different steels varies from below 60,000 to nearly 300,000 pounds per square inch one can readily see the importance of the tensile strength of the various parts that go to make up and complete the automobile. When the steels of the lower tensile strength are used, the sectional area of the piece, that is, the distance through the thickness, or the width, or both, must be greater than when the steels of the higher tensile strength is used. For many parts of the car almost any metal is sufficiently strong, and for these the metals of the lower tensile strength can be used, as these are invariably the cheapest. There are many parts, however, where strength is of vital importance, and for these it is necessary to know the tensile strength of the material to be used before the designer can say what size it is to be made or from what material.

The higher the tensile strength is in the steel the higher will be the cost of the materials used in its manufacture, as the greater will be the amount of labor and skill required in its manufacture. If steels of the lower tensile strength per square inch are used, the number of square inches in their sectional area must be much greater than when steels of the higher tensile strengths are used. This would make the various parts heavier than they need be and would add greatly to the weight of the complete car. It would thus require considerably more engine power to drive it than would be the case when metals of a higher tensile strength are used. The difference, therefore, between cheap metals that must be comparatively large in section owing to their low tensile strength and the higher-priced materials that have a high tensile strength and can be made comparatively small in section is often a difficult problem for the engineer and designer. Sometimes the high-priced materials are as cheap to use as the low-priced, owing to the fewer pounds that are needed from which to manufacture the given part. Occasionally a designer has used the cheaper material and made it the same size as he would the more expensive material, but this nearly always resulted in a breakage.

Some factors that affect the tensile strength of steel to a large extent and of other metals to a lesser degree are their mechanical working: that is, after steels are rolled, pressed or forged their tensile strength is considerably greater than when they are first cast into ingots. Likewise, the steels, especially, have their tensile strength greatly altered by their heat treatment: that is, annealed steels are considerably lower in tensile strength than steels that have been properly hardened and tempered. This greatly benefits the different parts of an automobile.

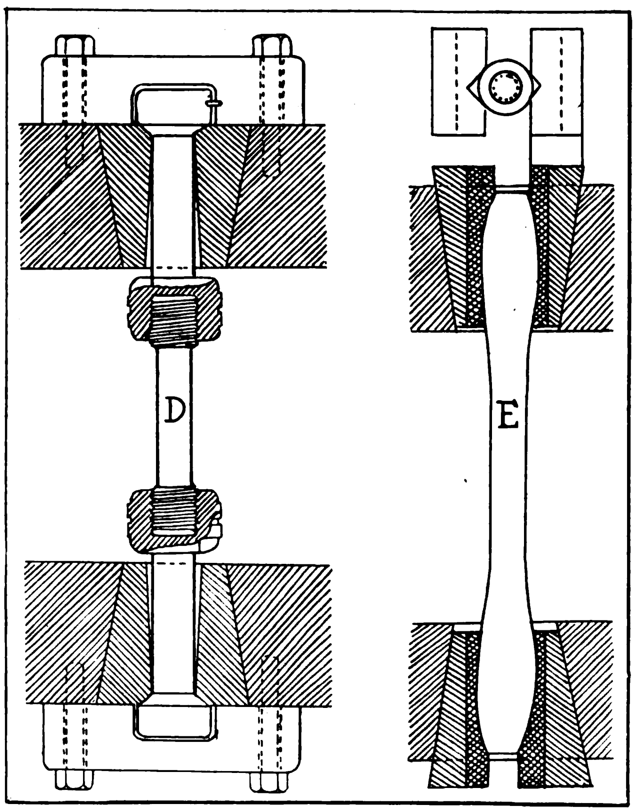

Fig. 2—Standard shape adopted for steel and cast iron test bars

It is not the purpose of this article, however, to go into details of design, what materials should go into the various parts or the working and treatment of the metal. Its object is to call attention to the necessity of having them of the required tensile strength.

Aluminum is very light but has very little tensile strength, this being from 12,000 to 20,000 pounds per square inch. It, therefore, is used for engine cases, gearboxes, and such parts as keep dust and dirt away from the working parts, and are not subjected to any great strains and stresses. It makes the car lighter and less engine power is needed to drive it.

An attempt is being made to use sheet metal for these parts, owing to the weakness of aluminum castings. The sheet metal would have a greater tensile strength for the same weight but is quite difficult to form into the shapes needed and supply them with the thick bosses and lugs that are required in various parts of such cases.

Other parts, such as carbureters, levers of many kinds, etc., are made from the brasses and bronzes. Castings from these vary in tensile strength from 30,000 to 85,000 pounds per square inch and are useful in many places where great strength is not required, but more strength than aluminum gives.

For many other parts malleable iron, cast iron, steel castings and other metals are used. These vary in tensile strength from the 5,000 to 10,000 pounds of the bearing metals to the 85,000 pounds per square inch that is shown by some steel castings. Bearing metals, however, only require compressive strength, which is the opposite of tensile strength. That is, instead of pulling apart the test bar, it is squeezed or compressed until it gives way or is crushed; the number of pounds required to crush it being its compressive strength.

Of the steel parts, such as steering knuckles and their connecting rods, the best of metals that have a high tensile strength must be used. Breakage of these means that the driver cannot steer the car and unless he can stop it suddenly, a bad accident is liable to occur. Quite a number of accidents of this kind have resulted in occupants of the car losing their lives. The crankshaft of the engine is another part that is given great strains every time an explosion occurs in the cylinders and this must have a good tensile strength. The driving shaft, axle shaft, transmission gears with their shafts and differential gears are some of the other parts that are subjected to great strains and stresses and consequently must have considerable strength.

The strains and stresses produced in an automobile by its traveling over rough roads make it imperative that the frame, front and rear axle, driving shafts and gears and all the moving parts have the required tensile strength, as on this largely depends its life and safety, as well as the safety of the car's occupants.

If any of the materials used are porous, spongy or full of blowholes there is an interruption in the cohesive force that binds the molecules of the mass together and hence it cannot have the tensile strength that it should.

Knox Adopts Long-Stroke Motor

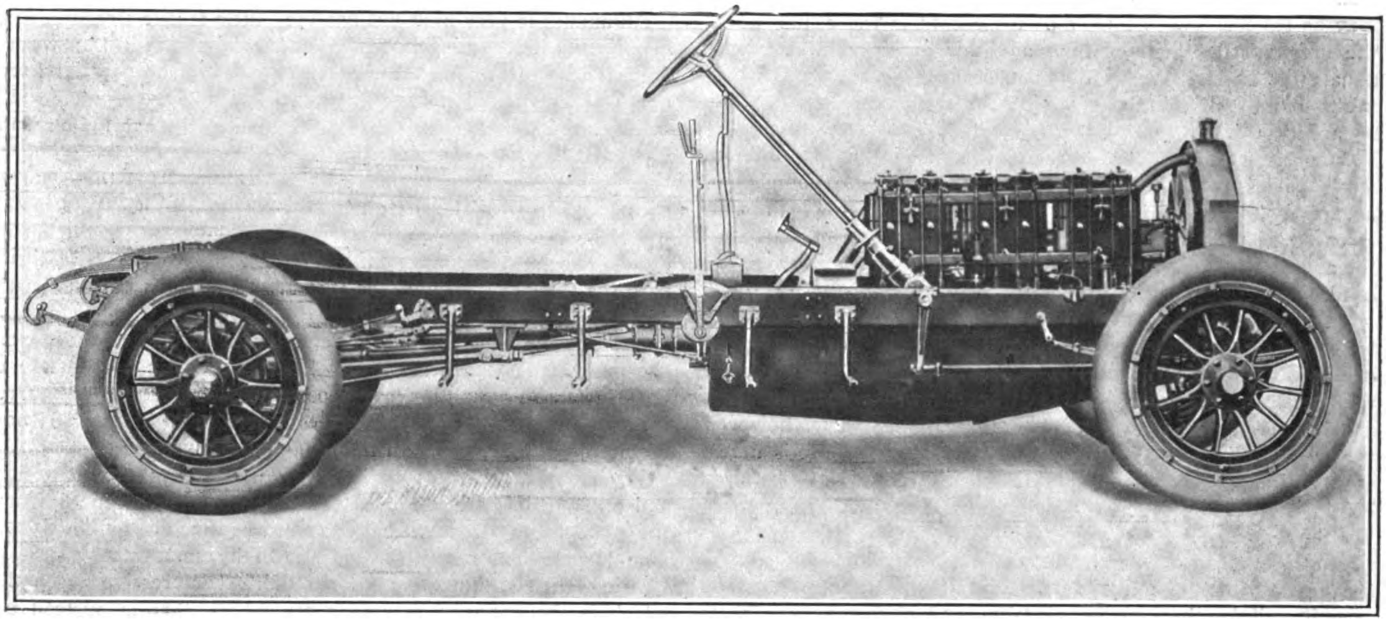

Fig. 1—Side elevation of the six-cylinder Knox chassis, showing suspension and control

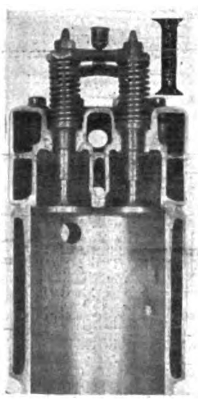

IN bringing forward the line of cars for the season of 1912, the Knox Automobile Company, of Springfield, Mass., has departed from its time-honored policy of building nothing but short-stroke motors and has adopted, in connection with the new chassis which features this year's output, a motor having a 1.1 bore-stroke ratio. The ratio which is used in connection with the other motors constructed by this company is .95.

The new motor has a bore of 5 inches and a stroke of 5.5 inches, giving a horsepower of 40, according to the A. L. A. M. rating. The motor has four individually cast cylinders, as may be seen in Fig. 3. The cylinders are water-cooled, the water-jackets being cast integrally with the cylinders. The valves are located in the cylinder heads and are operated by means of rocker arms R and tappet rods T, which take their motion from the camshaft C, located on the right side of the motor. The cylinder heads are removable, being attached to the body of the cylinder by means of four bolts which screw into bosses on the cylinder casting. A copper asbestos gasket is placed in the joint between the head and body of the cylinders so that it will be secure against leakage. The gasket fits into a deep groove in the upper part of the joint, while a concentric tongue fits into the groove G and holds the gasket tightly in place. The valves V are of the flat-seated type, according to the practice maintained by the Knox concern. They are made from a solid piece of nickel steel alloy and are of generous proportions, thus allowing for a wide seat. Both the tappet rods and upper ends of the valve stems have cup-shaped openings to receive the case-hardened ends of the rocker arm; oil is placed within the cup in which the ends of the rocker arms work in order to eliminate noise to the greatest possible extent and to prevent undue wear upon unlubricated surfaces. To further prevent noise an auxiliary is fitted in addition to the regular valve spring, thus making up all lost motion and increasing the efficiency of the whole mechanism. The regular valve spring and auxiliary are shown at A and B.

The crankshaft is a drop forging running upon five plain bearings which are carried on webs in the crankcase casting. The crank bearings are fitted with babbit bushings which are recessed, thus forming a firm bearing for the connecting rod. The pistons are flat-head castings having three rings above the wristpin and one near the bottom of the piston. The wristpin is firmly attached to the boss, into which it is fitted by means of a set screw S which passes completely through the pin and into the boss. The connecting rod bearing cap is fastened by means of four bolts of large diameter. These bolts pass through bosses in the connecting-rod end.

The camshaft which operates the tappets is made from a single solid bar of nickel steel, finished and ground to size. The cams and gears are cut integrally, while all the wearing parts are ground to size and then hardened. The shaft runs on three plain bearings which are lined with phosphor bronze; the central bearing is split and can be adjusted for wear.

Same Lubrication System Used

The new motor is lubricated in a manner identical with that of previous models of Knox cars. The system used is the force feed, the oil being kept in constant circulation by means of a gear type of pump. The pump is driven by means of a vertical shaft which is operated directly off the camshaft. This shaft not only drives the oil pump but also rotates the timer. The oil reservoir is in the lower half of the crankcase and forms an integral part of the engine casing. The oil level in the reservoir is never permitted to rise to such a height that the connecting rods will dip into the oil, as this would put too much oil into the cylinders and cause the motor to smoke.

The oil pump, which is of the gear type, draws the oil from the reservoir in the crankcase and forces it through the main oil feed pipe to the other side of the motor, where it is led into a longitudinal pipe. The leads for the main bearings are tapped into this pipe. Oil is forced into the crankshaft once in every revolution when the opening in the shaft registers with the opening in the oil lead. The crankshaft is drilled as well as the crank-checks and the crankpin; the oil flows along the crankshaft under pressure and is thrown into the crankpin by centrifugal force due to the revolving shaft. The crankpin has an opening drilled through it in a direction perpendicular to the axis through which the oil will flow to the bearing by centrifugal force. This opening registers with an opening in the lead to the wristpin bearing through which the oil will flow. A certain amount of oil is thrown from the cranks as they revolve and this suffices to lubricate the cylinder walls. The surplus oil drains back to the reservoir, whence it is again drawn through the system after having been passed through a wire mesh strainer.

A noteworthy feature in connection with the lubricating system on the Knox cars is the spring connection on the pump shaft. This is so arranged that in case the pump becomes clogged nothing important will be broken as the spring will snap past the catch. A pressure gauge showing the pressure head delivered by the oil pump is located on the sloping floor-board of the car. The oil is supplied to the tank on the left side of the motor and the quantity contained therein may be at any time determined by means of a level gauge cock.

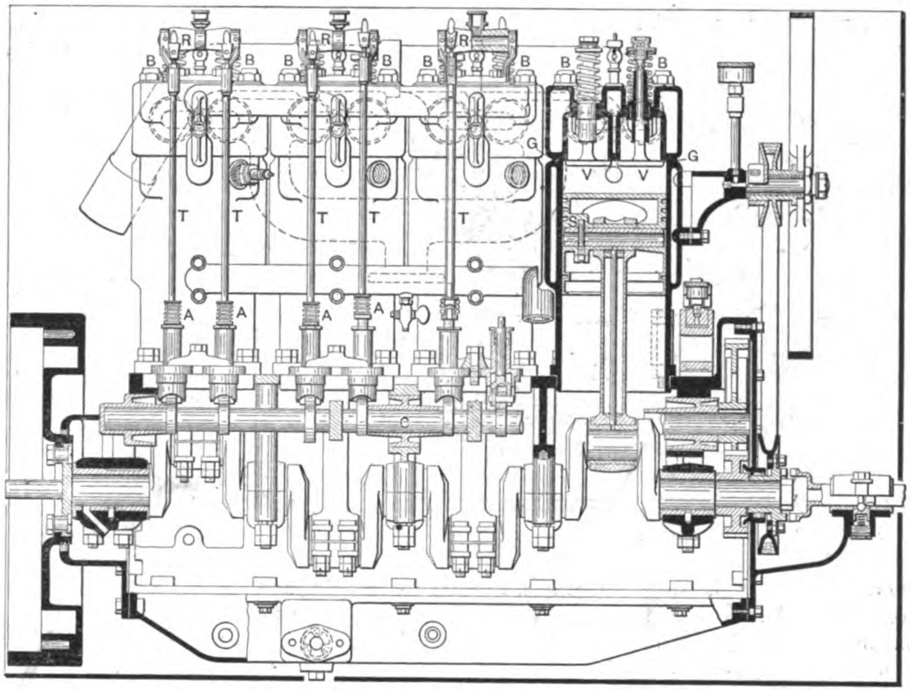

Fig. 2—View of the new Knox four-cylinder, long-stroke motor

Two Systems of Ignition

Ignition is effected by means of two independent sets of spark plugs, one of which is operated by means of a Bosch D-4 type magneto, located on the left side of the motor, while the other set of plugs for starting purposes is connected to a Columbia battery set and a 4-unit Connecticut coil. The two-way switch is located on the dash in the usual manner. These two systems are absolutely independent of each other and hence may be operated at the same time if desired, or in case of the derangement of either, the car may be readily run upon the other set.

The water circulation is maintained by means of a centrifugal pump. The water enters the cylinder jackets at the lowest point and has its outlet near the top on the right side. The water does not pass through the joint made by the connection of the cylinder head and cylinder castings, but passes from the lower casting into the upper by means of an outside fitting. Each casting, therefore, will have two water connections, an intake and an outlet. The radiator used in connection with the cooling system is of the tubular type.

The carbureter used is of the Stromberg make, having a single jet and float feed. It is located on the left side of the motor and supported by the Y-shaped intake manifold.

The clutch may be seen in Fig. 4. It is of the three-plate dry type and is provided with cork inserts in the cast-iron facing. The clutch is located in the flywheel as shown and the tension is maintained by means of coil springs which hold the frictional members of the clutch tightly in place. Easy disengagement is effected by means of the clutch pedal operated from the driver's seat, this pedal actuating a sliding sleeve which in turn disengages the plates. The whole clutch mechanism is enclosed in a dust-proof casing which serves to protect it from dirt and

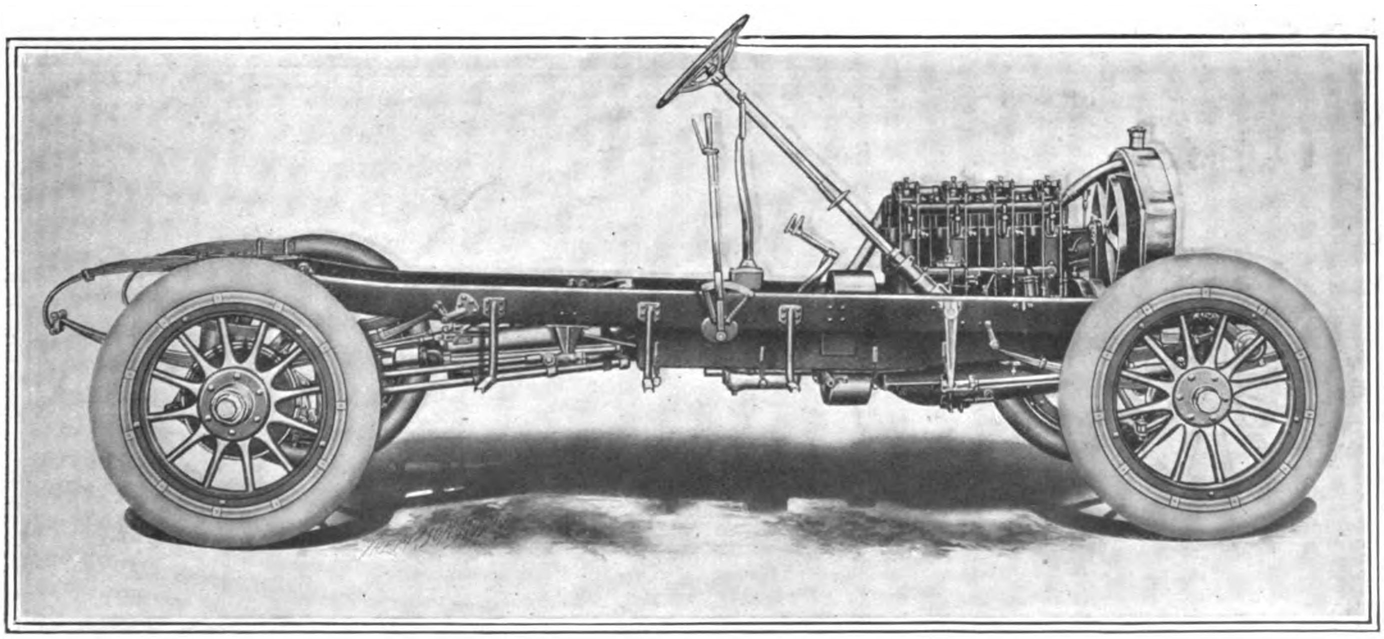

Fig. 3—Chassis used in connection with the Knox four-cylinder, long-stroke motor

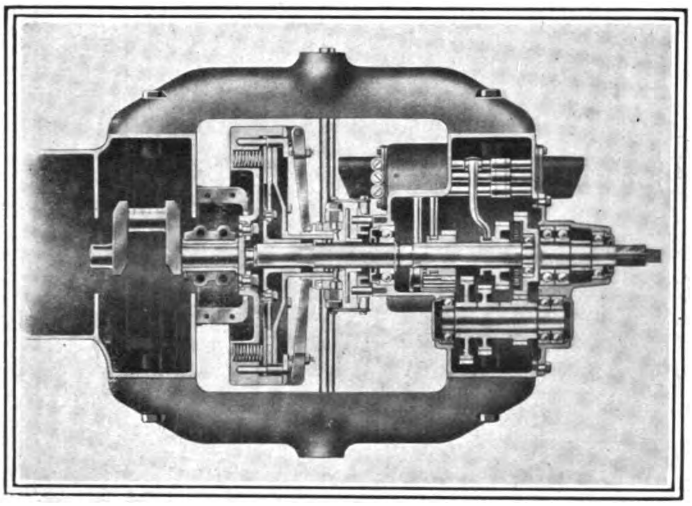

Fig. 4—Plan view of the clutch and gearset housing with the cover removed

water. The casing is easily removable, making the clutch parts accessible with little trouble in case it is necessary to make an examination or adjustment.

The gearset is of Knox design and is of the three-speed and reverse selective type which has been common to the Knox cars in the past. It is shown in detail in Fig. 4. A slight change has been made in one of the details of construction in that the rear of the main shaft and the lay shaft run on a double row of Hess-Bright ball bearings. Both the shafts and gears in this part of the transmission are made of nickel steel, the shafts being specially hardened while the gears are so constructed as to do away with keys. No universal joint is used between the clutch and the gearset, the two being so constructed that one is practically a continuation of the other. They are covered by the same housing and are separated by means of a packing gland inserted in a partition in the housing which serves to divide the clutch and gearset compartments as well as to provide a means of stiffening the construction.

Features of the Knox Drive

A universal joint is placed just aft of the gearset housing, separating it from the propeller shaft. Another universal joint is provided at the rear end of the shaft to take care of any changes which may occur in the alignment of the drive owing to the different compressions of the springs under varying loads. The power is transmitted through the shaft and then to the differential. The differential shaft is a short member and is carried by a ball bearing at either end. At the rear end the bevel pinion, which is an integral part of the short shaft, engages with the large bevel wheel which operates the differential; this gear wheel is also carried upon ball bearings which are supported by means of webs in the differential and floating axle housing. The axle shafts are also carried upon ball bearings at either extremity and are easily accessible by simply removing the hub cap, which discloses the ball bearings upon which they are carried. The live axles are squared at their inner ends so that they may be readily withdrawn for inspection, by simply pulling them out. The differential gears are very easily accessible also and may be taken out of the housing by removing the casing cover which is fastened by means of a series of small bolts. The differential and axle housing are of pressed steel while the gears themselves are of nickel steel.

The brake drums are located on the rear hubs. The service brakes are operated by means of a pedal from the driver's seat and are of the contracting type, having a face of 3 inches in width and 14 inches in diameter. The bands are held free from the drums at top and bottom by springs which are rendered adjustable by means of lock nuts. The emergency brakes are of the internal expanding type and are operated by a hand lever. A movement of the lever turns a cam which is so arranged that it will spread the two shoes of the brake apart, causing them to bear against the internal surface of the drum. The shoes are lined with Raybestos and are kept free from the drums when not in use by means of springs. Both brake outfits are controlled by equalizers which are so constructed that an equal pull will be exerted upon each brake.

Details of the Knox Chassis

The wheels are of the wood artillery type, equipped with Fisk bolted-on tires mounted on demountable rims of the same make. As an option, Universal rims and clincher tires may be had by the purchaser. The sizes usually fitted are 37 x 5 inches, although the rims will also accommodate 36 x 4.5-inch tires. The wheelbase is 126 inches and the tread the standard 56 inches.

The chassis frame is of unusually heavy construction and has a single drop. The depth of the metal in the new model chassis is 5 inches while the width of the channel flanges varies at different points along the length of the chassis in accordance with the distribution of weight and strains. The flanges of the side members widen rapidly from the attachment point of the front spring shackle and extend back with unusual width until past the point of power unit support, from where the flange tapers back to standard width. There are three cross members to the

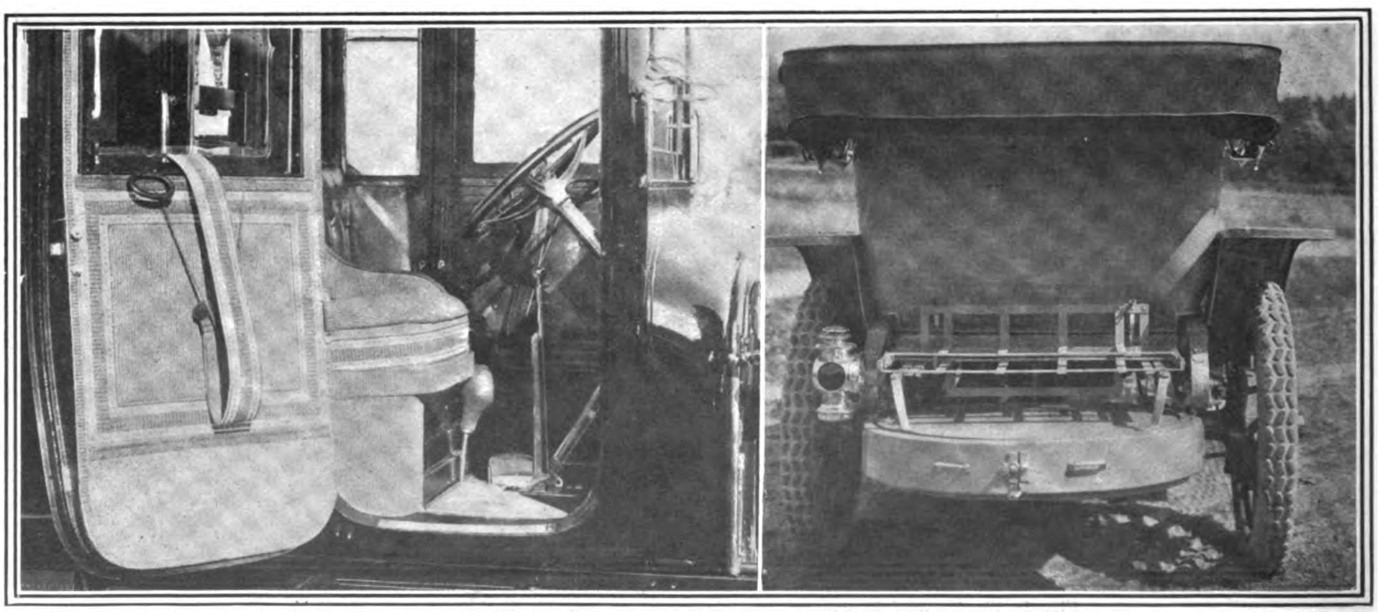

Fig. 5—Interior of the limousine and the rear of the touring model. Note tire trunk

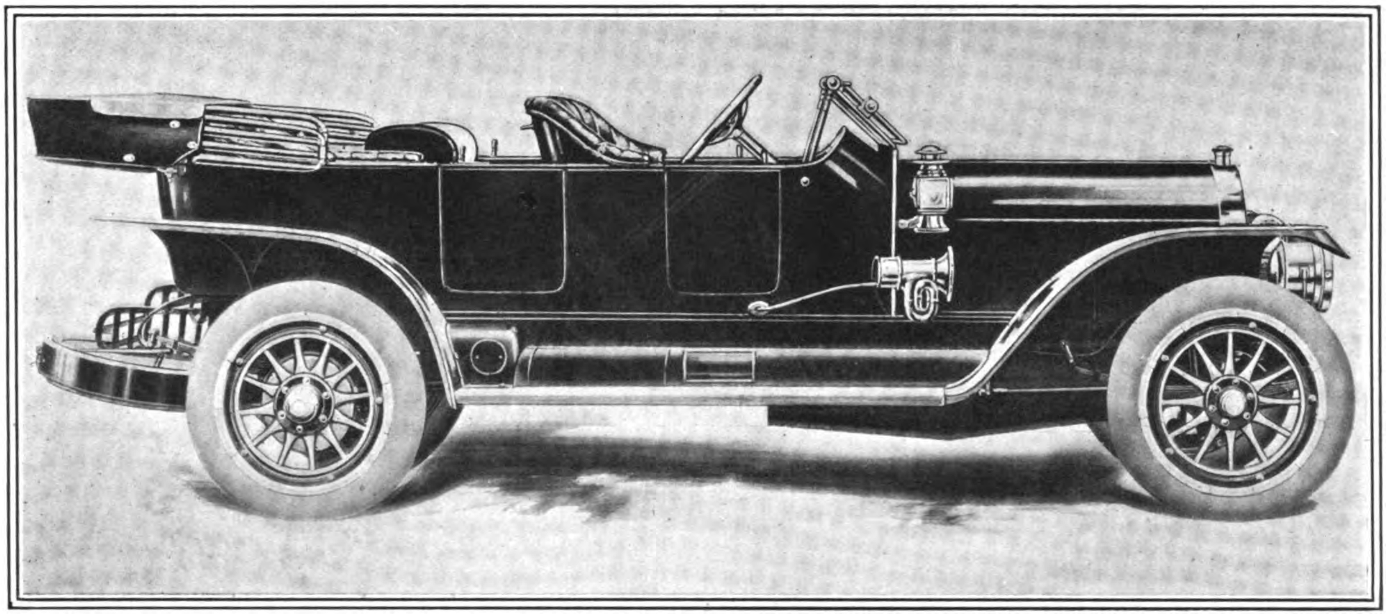

Fig. 6—The fore-door, seven-passenger touring car with six-cylinder motor

frame, one at the extreme front end, another at the rear and the third at a point just above the forward universal joint in the driving shaft. The latter carries the forward extremity of the torque rod. The two engine supports also form sub-cross members as they help to stiffen the frame, and in a somewhat lesser degree the three tubes in the brake mechanism help to do the same thing. The material of the whole frame, in so far as the main and sub-members are concerned, is of cold pressed, heavy gauge nickel steel.

Features of the Knox Suspension

Semi-elliptic front and three-quarter elliptic rear springs are used on all models of the Knox cars. The front springs are 42 inches long and the rear 54 inches. They are of alloy spring steel and are made by the Spring Perch Company. Shock absorbers are fitted to all the springs in order to give an easy-riding car with a long-lived suspension. Spring lubrication is effected by means of extra large grease cups which are fitted to the shackle bolts. Shackle bolts and pins are all hardened and ground to size.

Steering is done by means of an irreversible gear of the double left- and right-threaded worm type. The two worms are operated through an 18-inch hand wheel and are connected to the nickel steel rocker shaft by means of a drop arm. The steering column is bolted to the frame and secured in such a manner to the footboard that no vibration will be felt in the wheel. Adjustment for wear is readily made by means of a large nut located on the exterior of the steering gear housing. The fore-and-aft rod is straight and the socket ends are provided with springs to eliminate rattle.

The chassis described is known as the model R-45 and marks the first long-stroke motor built by the Knox people. The other models are the same as those made in former years. No marked changes have been made except in some minor details. The other models made are known as R, S, R-64 and R-3. They are all equipped with four-cylinder engines except the model S, which has a six-cylinder motor.

The equipment fitted to all Knox cars is complete and is as follows: Magneto with cover, Jones speedometer, Gray & Davis lighting system, Presto-O-Lite tank, combination oil and electric side and tail lights, horn, foot rail, robe rail, motor tire pump, gasoline gauge, extra rim, tire cover, tire carrier, number plate holders, steering knuckle covers, top and side curtains, windshield, clock, full set of tools, etc. The colors are optional with the purchaser and in the case of the limousine all the additional fittings necessary in this type of body are included. The tool boxes are arranged upon the foot-board in a convenient manner. The bodies are constructed throughout of sheet aluminum and steel over oak and ash frames.

A large number of details are left optional with the purchaser. These details are not only of minor importance but also embrace the principal features of the construction of a motor car. The motor is one of the optional points. The Knox company believes in the short-stroke motor and for that reason continues to feature them in their line of cars for the coming year; still, at the same time the great amount of popular feeling in favor of the long-stroke type of motor is recognized and hence this style of engine has been incorporated in the Knox line. The purchaser is given the choice of either the long or short motor in any model of chassis which he chooses to select. If the short-stroke type is specified on the regular stock model an additional charge is made for the installation of the long-stroke motor. The same latitude of choice is allowed as far as four- and six-cylinder motors are concerned or left or right control as well as in many other points throughout the car.

Radiators Starting to Freeze

The time of the year has now arrived when it is dangerous to leave the radiator unprotected. It may be well to remember that if 1 1-4 quarts of denatured alcohol are added to each gallon of water the mixture will freeze at 5 degrees below zero.

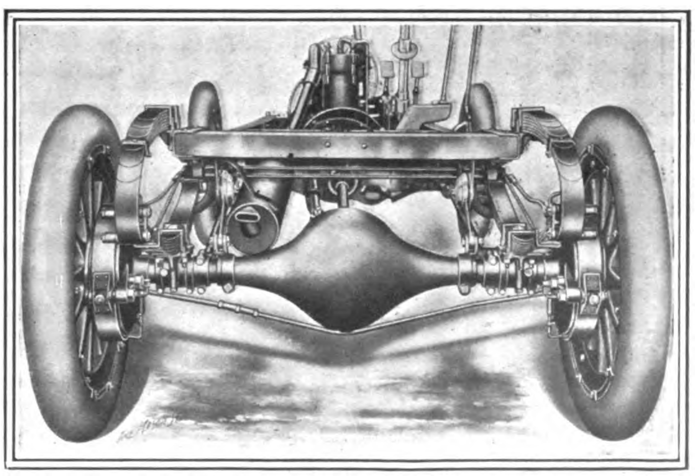

Fig. 7—Rear view of chassis, showing the Knox rear axle construction

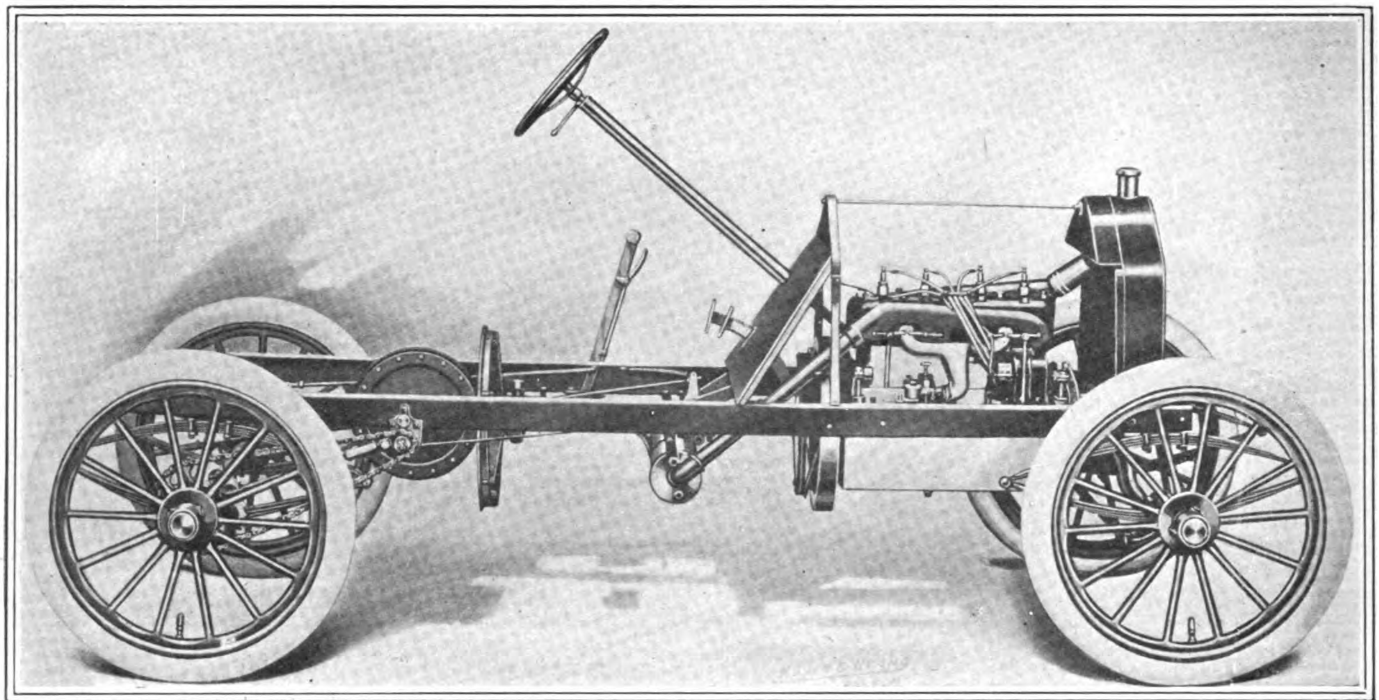

Fig. 1—The chassis of the 1912 Metz car is shown here in elevation

Few Changes Mark the 1912 Metz

THE Metz Company, of Waltham, Mass., makers of the Metz 22, have continued their product for the year 1912 without making radical changes in the design of the car.

The motor is rated by the makers at 22 horsepower and is of the four-cylinder en-bloc type. The bore is 3 3-4 inches and the stroke 4 inches. The motor is illustrated in Fig. 2, where it is shown partly in section so that a fair idea of the simplicity of design, which has been made a feature in the construction, may be obtained. The waterjacketing is cast integrally with the cylinders, the upper half being removable and held in place by means of stud bolts, which may be seen in the illustration. The manifolds are held to the waterjackets by means of the dogs D which are secured by the stud bolts that pass through them and terminate in bosses on the cylinder casting.

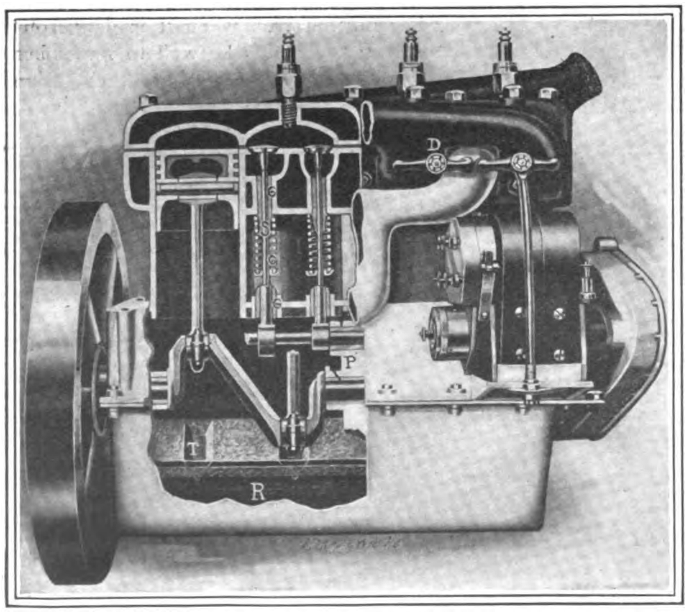

Fig. 2—Semi-sectional view through the Metz 22-horsepower. motor

The pistons are constructed with flat heads and are of square section, that is, having the same length and diameter. Three piston rings are fitted, all of them being above the wristpin. The wristpin is fitted within a bossing in the piston casting and is solidly connected thereto. It does not oscillate with the connecting rod. The connecting rod is of I-beam section and is fitted at the crank extremity with a cap which covers the bearing and which is fastened by means of two bolts which pass through bosses on the cap and connecting rod.

The crankshaft runs upon three main bearings, those at the extremities being supported by the walls of the crankcase casting, while the central main bearing is carried upon a bridge which is formed by a web in the casting. The camshaft is located upon the right side of the motor and operates both the exhaust and inlet valve actions. The valve-lifter action is simplified by having the cams act directly upon the push rods, thereby doing away with the lifter and follower mechanism generally employed. The camshaft is also carried by three plain bearings of ample length, located at the ends and center of the shaft.

The valves are of two-piece construction, the stems working in the guides G. The springs S are long and of sufficient strength to secure positive valve action. The spring caps C are flanged in order to hold the springs firmly in place and eliminate noise to as great an extent as possible.

The crankcase of the motor is cast in two parts, the lower half being independent, while the upper half is integral with the cylinder and waterjacket castings. The two parts of the crankcase are fastened in the usual manner by means of bolts which pass through the flanges. A packing is placed between them, thus eliminating oil leaks.

The motor is cooled by water which is circulated by means of a centrifugal pump. The water passes through a square tube radiator before being again circulated through the cooling system. The radiator is kept cool by means of a fan formed by the pitched blades of the flywheel. Easy circulation is maintained by means of the large waterjacketing space which is so arranged that it is not constricted at any point. The valve passages are also well cooled.

The carbureter is located on the right side of the motor, being supported by the intake manifold and the motor frame. The gasoline is fed to the carbureter through a straight pipe connection and flows by gravity. The tank is located behind the driver's seat and has a capacity of 7 gallons.

The motor is lubricated by the splash system, of which a good idea may be had from the illustration. The oil reservoir is contained in the lowest part of the crankcase and is shown at R, Fig. 2. The oil is put into the crankcase through the filler hole which is provided with a screen through which the oil must pass and which will remove any impurities or foreign matter from the supply. A gear pump which is actuated by the camshafts lifts the oil from the reservoir and places it in the upper part of the lower half of the crankcase. The splash troughs are located here and are shown at T.

An oil pocket is provided at P so that the central main bearing will receive an ample supply of oil. The oil is caught up in the pocket and then drains through the hole shown into the bearing bushing, which is thereby lubricated. The oil after having been used will drain back to the lower part of the crankcase by means of the overflow holes provided. It passes through a screen before reentering the pump to be sent through the system again. The capacity of the oil tank is 5 quarts.

The car is operated by friction drive with five speed changes. The power transmission is illustrated in Fig. 1, the shaft is continued past the flywheel and terminates at a point about amidships in a friction wheel. The other or driven member of the pair of friction wheels which characterizes this car is placed upon a transverse shaft which is carried upon bearings supported by the frame. The driven wheel rests upon a sleeve which can be shifted in a direction parallel to the axis of the shaft. When the perimeter of the driven member is in contact with the outermost circumference of the driving wheel, it is apparent that the maximum speed will be obtained. Variations in the speed may be had by shifting the driven wheel so that the point of contact between the two wheels is at different distances from the center of the driving member. Power is transmitted from the

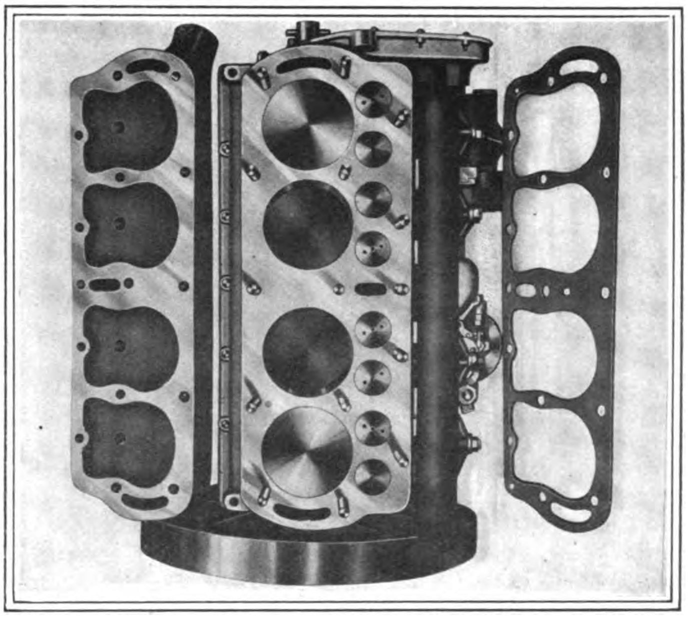

Fig. 3—Plan view of the en bloc cylinder casting on the Metz motor

transverse shaft to the rear wheels by means of two chains, one on each side of the vehicle. The ratio of reduction of the power from the transverse shaft to the rear axle is 4 to 1.

The brakes are located at the wheel hubs and are of the disc type. They are controlled by pedal from the driver's seat.

The chassis is hung upon elliptic springs both front and rear; the rear springs consist of four plates and are 1 1-2 inches in width and 30 inches in span, the front springs have exactly the same dimensions and constructive details. The front axle is of drop-forged manufacture. The side members of the chassis frame are of channel section straight construction, having a depth of 3 inches and width of 1 1-4 inches.

The wheels are of the artillery type, each having 14 spokes, and being provided with Mott steel rims. The tire equipment regularly fitted consists of a full set of 30 x 3-inch tires.

The car is sold fully equipped with high-tension magneto, tires, tools and top, and complete weighs about 1,000 pounds. It is designed for two passengers.

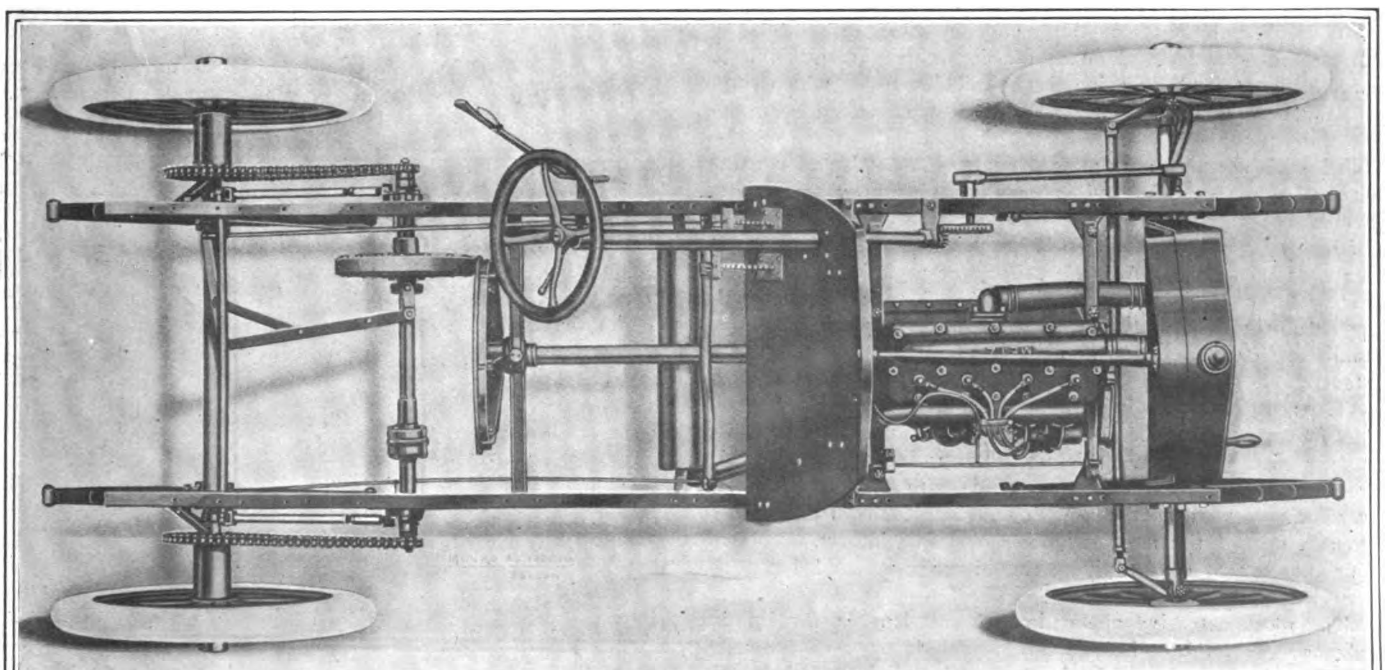

Fig. 4—Plan view of the standard Metz chassis, showing friction drive

Acetylene and Its Uses

ACETYLENE, as everyone knows, is generated when calcium carbide is brought into contact with water. Carbide is a compound consisting of calcium (a metal which may be burned to form lime) and carbon (the element used wherever heat is to be produced in commercial quantities). Calcium carbide, however, is not made directly from its elements, calcium and carbon. It is produced by heating, in the electric furnace, a mixture of lime (calcium oxide) and coal (carbon). In this process part of the coal combines with the oxygen of the lime and is freed as carbon dioxide, while the rest of the coal reacts with the calcium, resulting in the formation of calcium carbide. But this reaction takes place only at a very high temperature, and during the process vast quantities of electric energy are absorbed by the carbide and stored in a latent form of energy, generally referred to as chemical energy.

Owing to the low price of carbide, its production may be profitably carried on only where electric power is available at a low price, such as near a waterfall, and at places not too remote from the localities of carbide consumption.

If water is poured on calcium carbide the following reaction takes place: Water, which consists of hydrogen and oxygen, loses its oxygen content, which combines with the calcium and forms lime; the carbon of the carbide and the hydrogen of the water form acetylene gas, which has the formula C_2H_2. One pound of acetylene is composed of 12-13 pound of carbon and 1-13 pound of hydrogen, and contains about 17,500 B. T. U. This is a tremendous amount of energy, and since the lime by the formation of acetylene contains no more energy than it originally possessed this number of B. T. U. represents the total of the energy absorbed in the electric furnace. The usefulness of acetylene is founded upon this high energy content, which, however, is also a source of danger, especially so if impurities are taken up by the gas. If this is the case acetylene is liable to be decomposed into its elements, carbon and hydrogen, and the high energy content to be set free, causing a considerable detonation.

Pure acetylene has hardly any smell at all. The stench popularly ascribed to it is caused by the impurities often contained in it. The dangers accompanying impurities in acetylene are practically obviated by using the so-called autogas, which comes in tanks. Here the acetylene is dissolved in acetone, a by-product of wood-tar distillation. In filling the gas tanks, these are first filled with acetone, a gelatinous mass. Then the acetylene is pressed into the tanks and is readily absorbed by the acetone, which, under a pressure of 176 pounds per square inch, is capable of dissolving acetylene of a volume 300 times its own. In this state, acetylene is quite a safe substance; a platinum wire made incandescent in a hermetically sealed full tank fails to ignite or decompose the acetylene. Besides being explosion-safe, gas tanks are clean, economical and may be put in use almost instantly.

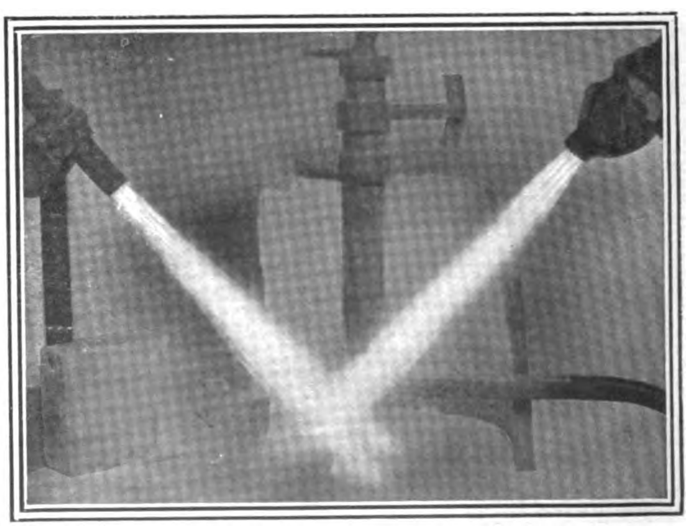
The acetylene emerging from gas tanks is pure and therefore less dangerous than the impure gas, when it comes in touch with copper pipes. Copper, as is well-known, is very apt to form verdigris if given a chance to combine with water and air, and verdigris, in turn, combines with acetylene to form acetylide of copper, one of the most explosive materials known. It is for this reason that copper piping should never be used for acetylene leads.

The most extensive application of acetylene is for lighting purposes. Acetylene has quickly found favor with the automobile public because of its intensely white light, which is generally considered the whitest artificial light and, in fact, is as white as sunlight. The cause of this phenomenon lies in the high energy content of the acetylene. The 17,500 B. T. U. contained in 1 pound of the gas develop a very high temperature—about 2,300 degrees Centigrade—if the gas is ignited. At this temperature carbon is white-hot, producing the purest white light there is. The high carbon content of acetylene, remembering that it constitutes 12-13 the weight of acetylene, accounts for the enormous quantity of white light produced by a very small flame. If a reason for the ability of carbon to produce a high temperature is sought it may be found in its black color. Black matter heats up much more rapidly than white material, and, just as in walking in the sun, a black coat seems much warmer than a white one, so coal, when it is heated, quickly attains a much higher temperature than silver or platinum, for instance. If a coal mark be made on a platinum sheet, and the sheet heated in a flame, the coal mark becomes white hot before the platinum heats up to red glow. The higher the temperature of the heated metal the more intense becomes the light radiated by the coal marks.

Likewise, in an acetylene flame the intensely white light is made possible only by the high temperature of the burning carbon. Superficial measurements of the heat of an acetylene flame in open air would indicate an average temperature of about 1000 degrees Centigrade. Numerous and detailed experiments, however, have revealed the fact that in the portions of the acetylene flame which radiate most of the light the temperature is about 2,300 degrees Centigrade.

Use of Generator Tanks Has Good Features

In place of the gas tanks in which acetylene is stored and transported many automobilists use generator tanks, containing calcium carbide, to which water is added when acetylene gas is required. Most generator types contain carbide, and in order to develop acetylene gas, water is permitted to drip upon the carbide. This process is simple but has many disadvantages, especially that the carbide ashes are apt to harden quickly in this process, which is accompanied by a waste of carbide. Furthermore, the material heats up quickly and part of the acetylene is decomposed immediately. A more advantageous manner of producing acetylene for use on a car would be to have the

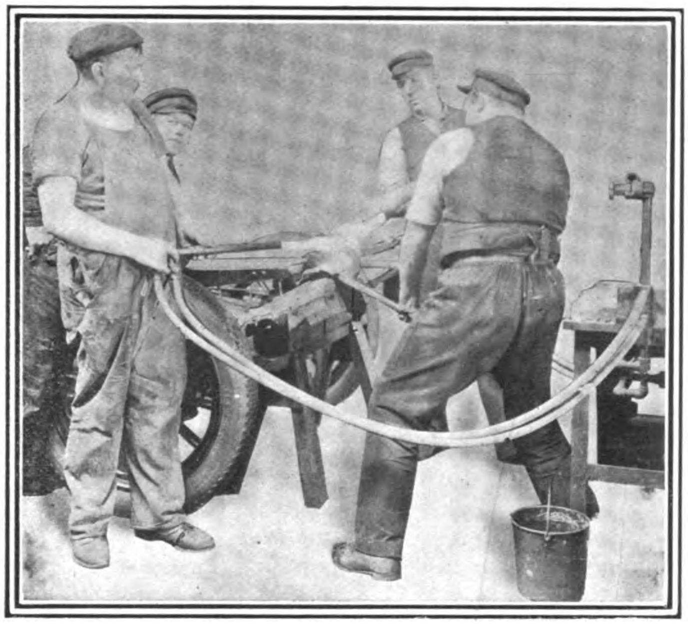


Where large portions are to be welded, two or more oxy-acetylene flames may be used to advantage carbide grains drop into the water, whereby all the above setbacks would be avoided. But, since the construction of a generator of this type is more complicated than that of the water-on-carbide class, very little has so far been done along the carbide-in-water line despite the advantages of this system.

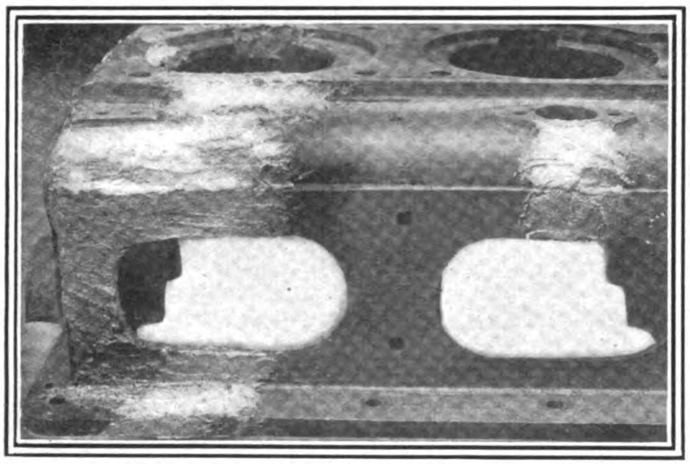
In order to prevent the freezing of the generator water in Winter, anti-freezing ingredients should be added, among which a small percentage of denatured alcohol is highly recommended. Salts dissolved in the water are apt to cause rust or verdigris on the gas fittings; this should always be avoided. A solution of sugar also has its good qualities, and, like the alcohol solution, reduces the violence of acetylene generation when water is admitted to the carbide.

Autogenous Welding Opens a Wide Field

The most important application of acetylene, aside from illumination purposes, is for autogenous welding. Welding is a process of solidly joining two pieces of the same metal, without the use of a solder of a different material. Where common solders are used the work of uniting two pieces of metal may be done at a low temperature with a correspondingly low consumption of heat. But the strength of the union formed is also a low one, and where a strong metal member, such as a crankshaft, is broken and must be repaired, it is necessary to consider the fact that this part will have to do much work and is subject to great kinetic stresses. Therefore the repaired part must be made fully as strong as the unbroken portions, and to attain this end it must be welded.



Executing an autogenous-welding job on an automobile. Two men handle a flame each and another assists



How a broken crankcase is welded by the oxy-acetylene process, after which it is ready for finishing

The difference between the ordinary welding process and autogenous welding lies in the fact that the smith heats the parts to be welded until they get soft and then unites them by hammering, whereas in autogenous welding the portions adjacent to the fracture are brought together and heated to their melting point. The principal point in autogenous welding, therefore, is to produce a temperature in which iron—or the material to be welded—melts. In this case only the portions to be welded may be heated in a very short space of time and the job may be finished ere the neighboring portions begin to heat up. For this reason a very small acetylene flame may be used, this producing a high enough temperature over a small range.

The high conductivity of metals would not permit the flame to get hot enough to melt them if it were left to the flame suction to supply the air necessary to produce the high temperature above mentioned. For this reason compressed air, or rather oxygen, is led into the acetylene flame, causing a flame similar to that of the blow-torch. Oxygen is applied in preference to compressed air, since, if the latter is used, the 80 per cent, nitrogen contained in the air must be heated at the expense of the energy content of acetylene and oxygen. The best possible effect is obtained by mixing the two gases in a mixing chamber.

It may seem quite remarkable that this very explosive mixture of acetylene and oxygen does not fire back into the gas lead, which would result very seriously. The same point may be raised in connection with the use of a gasoline blow-torch. But the reason why this never happens is easily found. To make it possible for the flame to backfire into and ignite the mixture in the gas lead the velocity of the burning gases would have to be in excess of the speed with which the mixture is forced out of the nozzle. To avoid this the nozzle aperture is made so small that, together with the pressure of the mixture in the gas line, it fully balances the tendency of the flame to backfire. In addition to this, copper gauze screens are inserted in the gas pipe, so that should a flame find its way into the interior of the pipe it would instantly be cooled and extinguished.

The principle of autogenous welding seems to be simple enough, but the work is not so very easy, because the process requires more than that the fractured pieces be melted and pressed together. The repaired portion needs to be quite as strong as it was before fracture, or it will not be able to sustain the stresses imposed upon it. But the high temperature to which the metal is submitted may bring about some change or other in its chemical composition or structure, and therefore some skill is required to obtain the desired result.

Besides acetylene only hydrogen has been practically considered so far for the purposes of autogenous welding. But, at the present high prices of power, hydrogen cannot be produced as cheaply as acetylene, and it is troublesome to transport. The most common way of producing hydrogen is by treating zinc shavings with dilute sulphuric acid. Only recently a compound named hydrone has been placed on the market which, if it is brought into contact with water, develops hydrogen as carbide develops acetylene. This material seems to offer some possibilities of a more general use of hydrogen.

While it is acknowledged that hydrogen is still more combustible and therefore more dangerous than acetylene, the oxy-hydrogen flame utilizing a similar apparatus as the acetylene autogenous process has been perfected to practical usefulness. The same flame offers also great possibilities in respect to illumination. Limelight, so eagerly striven after by many, is produced by the point of an oxy-hydrogen flame heating a pivot of lime. The possibility of an adaptation of limelight illumination for automobile use is by no means a small one, and the system producing a limelight on as safe a basis as acetylene illumination stands on to-day, would no doubt find numerous motorists ready to adopt it.

Digest of the Leading Foreign Papers

Safety Starting Cranks--II.

THE French Society for the Prevention of Accidents to Workmen instituted a competition this year for designers of safety cranks, with a view to standardizing a method for avoiding the accidents now frequently caused by the involuntary reversal of a crank's direction of rotation, especially in the starting of automobiles and in the use of winches and hoisting apparatus. Three of the cranks submitted in this competition were described and illustrated in THE AUTOMOBILE of October 26. Three more are described herewith and illustrated in Figs. 1, 2 and 3.

In the crank designed by V. Morland the extension motor shaft is grooved at the end, and the keypiece B (consisting of the keypiece proper and a square shank with dog C), which is inserted in the back of the crank, engages the groove and carries the crank along when the position of the lockpiece D is such as to permit the spring R to press the keypiece home. To regulate the position of D it is provided with a stubshaft carrying a pawl, which, in conjunction with the stationary ratchet wheel G (which is fixed upon a sleeve in which the motor shaft extension rotates), prevents D from following when the crank is rotated in the wrong direction. By a very slight movement of the crank in the wrong direction the cam groove in D consequently throws the dog C upward, against the resistance of spring R, and, as C is part of keypiece B, thereby at the same time releases the crank from the motor shaft. In the drawing, Fig. 1, the cross-section taken along dotted line *aa* is seen from the motor side, and the pawl is shown in dotted lines. It is seen that not only the reversal of the motor shaft, but the reversal of the crank as well, releases the latter, and this feature enables the operator to place the crank in the suitable "twenty-five minutes to" position for a starting movement in every instance. (The description and also the drawing of the Morland crank, as given in *Bulletin Officiel*, seem inconsistent with true mechanics at several points, and both have here been modified somewhat, so as to represent the principle of the crank correctly, as it must be.)

A crank designed by Louis Royer consists of a crankhub 1, 2, 3, 4, of which 1 is smoothly cylindrical and forms the bearing for a sleeve A provided with the customary clutch arrangement for gripping the motor shaft and at its front end formed with a conical surface K. Part 2 is formed with a square thread of steep pitch engaging a correspondingly threaded sleeve formed exteriorily as a ratchet wheel and provided at its rear end with a conical surface F adapted to form a clutch with the hollow cone K. Part 3 is screw-threaded to secure the flanged nut D, which serves as abutment for spring C, the latter exerting a pressure upon the end of the ratchet sleeve, acting through the medium of a ball bearing. To part 4 the crank handle M is secured. The crank is shown in the drawing as one to be turned "against the clock" for starting the motor. The combined pawl and lock bolt T, when let down upon the ratchet sleeve behind the ratchet teeth, prevents any engagement of the crankhub with the motor shaft. To start the motor T is raised by hand and dropped into engagement with the ratchet teeth, the crank mechanism being at the same time shoved back, against the resistance of spring U, to engage the motor shaft. When the crank is turned in the right direction the thread of part 2 forces the ratchet sleeve into driving engagement with the sleeve A, while T, now acting as pawl, slips over the ratchet teeth. If the motor shaft is turned in the opposite direction, any incipient reverse movement of the crankhub makes the pawl stop the ratchet sleeve, while the action of the steep thread draws the conical surfaces apart and releases the crank mechanism, excepting sleeve A. (It seems, however, that pawl T may be in a position in immediate proximity to the stop face of a ratchet tooth, when the reverse action begins, which will leave scant chance for any rotary action to release the cone clutch.) The spring C is intended for pressing the ratchet sleeve forward on the steep thread sufficiently for avoiding lost motion in bringing the cone clutch into engagement, but not sufficiently for a working engagement.

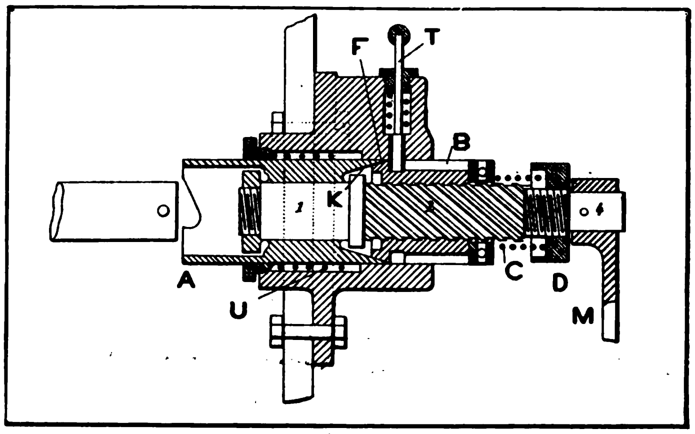


Fig. 2—The Louis Royer safety starting crank

The Duperron crank is of pleasing simplicity. To get the clutch B in engagement with the motor shaft A at the pin D, the pin G on the crank axle must engage sleeve E, which carries a ratchet wheel R, upon which acts pawl F, itself pivoted in the fixed plate S secured to the chassis. If the motor kicks back, the ratchet wheel is stopped by the pawl and the oblique edge in the clutch notch of sleeve E throws the crank out of engagement with the motor shaft. To make sure, the notch in E is deeper than that (or those) in B.

In the competitive trials of the cranks, prizes of 300 francs each were awarded for the Clemencet, the Duperron and the Morland cranks, but none of them was considered all that could be desired. Honorable mention was accorded for the other cranks here described.—From *Bulletin Officiel*, September.

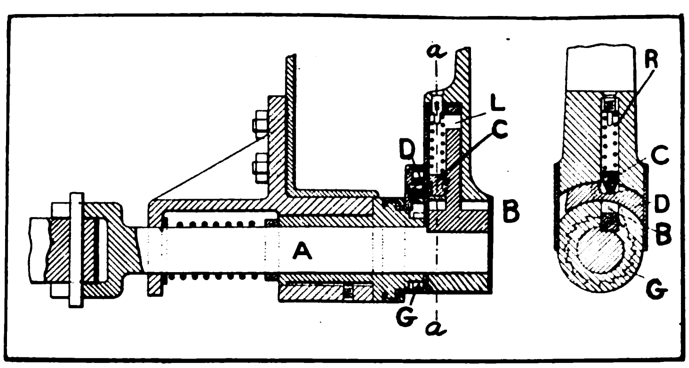

Fig. 1—The Morland safety crank, longitudinal section and cross-section on line *aa*.

FORCE-FEED SPLASH OILING FOR CHEAP CARS—The system has been tried out during the past two years and found good. The lower part of the sump (which is the rather expressive term

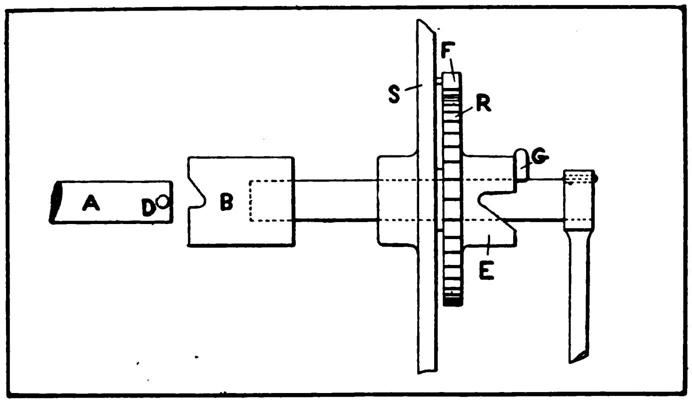

Fig. 3—Side View of Duperron Safety Starting Crank

used in Great Britain for the lower half of the crankcase) forms the oil reservoir, and at the bottom of it a pump is mounted horizontally and driven by a worm machined upon the camshaft, which meshes with a helicoidal gear upon the pump body. The pump drives the oil through a tube to a collector, from which it is distributed under the pump pressure to the crankshaft and camshaft bearings. Under each of the connecting rods there is formed a saucer into which drains the surplus oil from the crankshaft oil channels, and each connecting-rod knuckle carries a little cup which dips into the corresponding saucer at the bottom of the stroke, picking up a determined quantity, which rises to the connecting-rod bushing through holes provided for this purpose. With an ample discharge from the pump, the system evidently has the advantage of a constant level splash feed, being independent of the oil level until the same gets so low as to rob the pump of its supply, and it seems to have the additional virtue of being sparing in the quantity of oil which it sends to the cylinder walls and to the piston pin. An oil-circulation indicator on the dash secures the pump supply.—From description of La Buire car in *La Pratique Automobile*, October 25.

Wire and Wood Wheels—The superior strength, at equal weights, of the wire wheel over the wood wheel does not depend, according to the Rudge-Whitworth company—whose detachable wire wheels are gaining much ground in Europe—upon the intrinsic properties of steel in comparison with other materials on a weight basis, but almost solely upon the fact that the steel, with its much higher density, takes up much less space for a given strength and therefore may be applied to the suspension design of wheels which, on the other hand, is impracticable with the more bulky materials. The suspension wheel, in which the rim is in compression and the many spokes in tension, is a far more efficient design, says the firm, than the artillery wheel in which the relatively few spokes are in compression and subject to bending strains and the rim is in tension. Owing to the crossing of spokes and the very large joints which would be required, a wood wheel built on the suspension principle would be ten times as broad as a wire-spoked suspension wheel of the same load carrying capacity. The point in understanding raised by the firm is illustrated in the accompanying table.

Strength in Pounds of Wheel Materials.

	Weight of one cubic foot.	Elastic limit, pounds per square inch	Tensile strength, pounds per square inch.	Breaking pull of piece 1 foot long weighing 1 pound.	Elastic limit of piece 1 foot weighing 1 pound.
Steel spokes	490	135,000	157,000	46,140	39,680
Aluminum, 97½ per cent. alloy rolled	170	15,000	26,000	22,030	12,710

—From *The Car*, October 15.

Harking Back a Decade

From *The Motor Review* November 21, 1901:

Henri Fournier is planning to establish a factory in the United States to make a racing machine under patents of his own. The capital is said to have been promised by Foxhall Keene and other New York millionaires.

The withdrawal of the Apperson brothers from the Haynes-Apperson Company means that an entirely new type of automobile for four passengers and equipped with tonneaus exclusively will be made by the former.

The I. A. Weston Company, of Syracuse, N. Y., has purchased the entire plant of the Jamesville Manufacturing Company and will make automobile axles and other steel parts for motor cars and horse-drawn vehicles.

At the coming South Carolina and West Indies Exposition, which opens at Charleston December 1, there will be a large display of automobiles. The Wagener Driving Park course will be used for motor racing and demonstration.

The H. H. Franklin Manufacturing Company, of Syracuse, will be reincorporated shortly with an increase in capitalization from $100,000 to $250,000. It is intended to commence the manufacture of motor vehicles at once.

As was done at the New York automobile show, the track at the Coliseum, Chicago, will be abandoned this year. The pressure for space was so strong that the 7,000 square feet formerly used for a track will be divided into show spaces.

Alden L. McMurtry, with his new 16-horsepower Packard, weighing 3,600 pounds, recently climbed the Buena Vista street hill in Pittsburgh, a feat never accomplished heretofore with a motor vehicle.

The Knox Automobile Company announces that it took enough orders at the recent show to keep the factory busy for a month. Next week, it is announced, day and night shifts will be installed to fill orders and prepare stock for next summer.

Constant Huret, a well-known French chauffeur, has been arrested in Paris for abducting a gendarme and exceeding the speed limit. It appears that M. Huret stopped his automobile in the Bois de Boulogne and an officer stepped aboard to caution him about speeding. Huret dropped in his clutch and carried the minion of the French law several miles before obeying his orders to go to the police station.

Henri Fournier, driving a Mors racer, broke the world's mile straightaway record last week on the Ocean Parkway, Long Island, making the distance in 51 4-5 seconds. This is 5 1-5 seconds faster than the best time ever made for that distance even in France. The circular track mile record made by Alexander Winton in a Winton still stands at 1:06 2-5.

The timing was done by stretching a rubber hose across the starting line. Inside the hose were two strips of copper and the passage of a contesting car was supposed to press the two copper surfaces together, thus closing an electrical circuit. The impulse given by this was intended to convey a flash to the finishing line. On paper it seemed reasonable, but in practice it failed dismally.—*Editorial.*

The Stearns Steam Carriage Company, of Syracuse, announces that it is putting out twenty-five more traps of the latest design. These cars are equipped with a new gasoline generator which makes possible the use of a low-grade gasoline and will generate 150 pounds of steam from cold water in 10 minutes.

Letters Answered and Discussed

Adjusting Worn Valves

EDITOR THE AUTOMOBILE:

[2,917]—I have had the valves on my car ground often, taking it altogether, as my car is very old. I am sure that the valve timing has become affected owing to the number of times this has been done. Is there any way of compensating for this change in the valve position? J. R. C.

White Plains, N. Y.

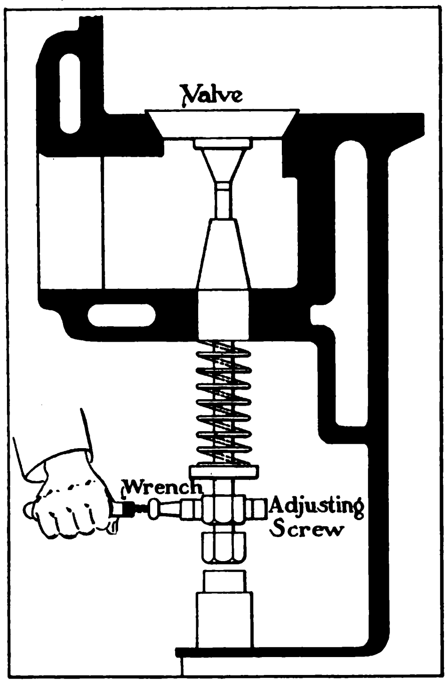

Fig. 1—Showing method of making adjustments on worn valves

In grinding down the valves the total strength is decreased by the amount that the depth of the valve is reduced by the grinding. This may be compensated for by making the adjustment shown in Fig. 1. The nut shown is turned and the length of the stem increased.

Leave Breather Pipe Open

Editor THE AUTOMOBILE:

[2,918]—Will you kindly answer the following queries through the columns of your paper:

(1) Is there any chemical less expensive and with which there is less evaporation than alcohol, which might be put in the radiator to prevent freezing?

(2) I have fitted a funnel with a tight lid on it to the breather pipe opening of my four-cylinder motor in order to keep the dirt out and for convenience in pouring in oil. Should this breather pipe be left open for any reason? E. C. N.

Juniata, Pa.

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

(1) Glycerine is used extensively to make an anti-freezing solution. The proper amount of it to add to the cooling water should be determined by the local weather conditions. The following table gives the freezing points of glycerine solutions:

10 per cent. glycerine freezes at	30 degrees F.
20 per cent. glycerine freezes at	27 degrees F.
30 per cent. glycerine freezes at	21 degrees F.
40 per cent. glycerine freezes at	0 degrees F.
50 per cent. glycerine freezes at	–25 degrees F.

(2) The function of the breather pipe is to relieve any compression which may be produced in the crankcase, and obviously it should not be closed. The end of this pipe is usually covered with a wire gauze to prevent dirt from getting into the crankcase, and if you put oil into the latter through this pipe, you can fit a funnel to it which has a strainer inside.

Testing Magneto with Bell

Editor THE AUTOMOBILE:

[2,919]—I would greatly appreciate it if you could give me a little information on the ignition system of my Ford Model T car. I wish to test the coils and would like to use a common magneto bell such as I use for testing for grounds and open circuits in electric lines.

If the coils are in good order, how should they act in connection with the magneto bell and how should the same be connected to the coils? J. L.

Mellen, Wis.

The bell may be readily used to test the magneto coils. The manner in which it should be connected is as follows: Remove the contact spring and place one end of bell circuit at contact point and the other on different parts of the engine frame, which is grounded; if the bell rings, the coil is all right insofar as the wire therein is concerned, and will then have to be tested for short circuit. This test is made by removing the magnetic field and coils and connecting the bell circuit to the contact point and then to the plate by means of which the circuit is grounded to the engine frame. If the bell rings when contact is made, there is a short circuit in existence which will have to be found and eliminated.

Misses When Speeded Up

Editor THE AUTOMOBILE:

[2,920]—I am very much troubled with my engine, which misfires when speeded up beyond 12 miles per hour on the high speed. I blamed the carbureter at first, but after cleaning and adjusting it and examining the whole gasoline line I am convinced that the trouble lies in the ignition system. At the same time I cannot see how it will work at low speeds and not at high. Can you help me out? ALEXANDER CARROS.

Pueblo, N. M.

Examine the timer to see if it is worn, if not, your vibrator is not correctly adjusted. To remedy this, turn the screw on the outside of the coil box until the trembler gives a good clear humming sound at all speeds. The manner of making the adjustment is illustrated in Fig. 2.

Regarding Reverse Ratio

Editor THE AUTOMOBILE:

[2,921]—Would like to have the question of reverse gear ratios aired a little. In several cases, if I am not mistaken, the reverse gear ratio is about the same as the intermediate ratio forward. Now I have always taken it for granted that the reverse should be even lower than the lowest forward speed to allow of the same turning effect to reach the rear wheels through the less efficient reverse gearing as through the low speeds forward, thus enabling the car to be maneuvered into or

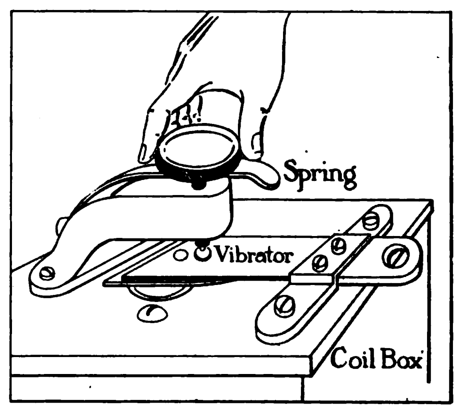

Fig. 2—A badly adjusted vibrator is often responsible for an elusive miss

out of any situation desired. I did not know there was any need of any higher speed in the reverse than the common ratio provided. A. D. KELLOG.

Eureka, Cal.

If there is any gasoline car manufactured whose reverse speed is higher than the lowest forward speed, it has not become known to us.

Likes Kerosene Idea

Editor THE AUTOMOBILE:

[2,922]—Your answer to question 2895, issue of October 2, relative to using kerosene in the radiator of the automobile in place of water would seem to indicate that there would be no permanent injury to the cylinders or motor from the use of kerosene in place of water. Now if this be true, why not use kerosene in cold weather in place of alcohol when it is possible to purchase it for the small price of 6 or 7 cents per gallon, where alcohol is so much more expensive?

It seems to me that it would be much cheaper to use kerosene in cold weather unless there is some injurious result to offset the difference. Kindly give a little light on the subject and greatly oblige a constant reader of your magazine.

FRANK CONE.

Findlay, O.

So far as can be seen without actually trying the experiment there should be no deleterious effects arising from the use of kerosene beyond the fact that the engine would heat up, unless the weather were very cold, owing to the low specific heat of the kerosene. In a climate where the days are warm and the nights cold, as is often the case at this season of the year, kerosene would probably not cool the engine as well as it should during the middle of the day.

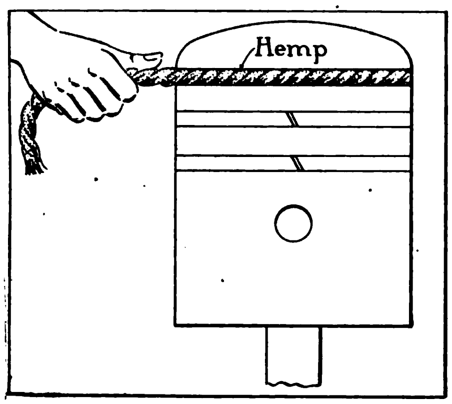

Fig. 3—The life of piston rings may be prolonged by the use of hemp

The freezing point of kerosene is rather uncertain, and if you have experimented in this direction sufficiently to obtain definite and satisfactory results, the scheme you suggest may be tried with success in very cold weather. Kerosene will certainly not affect the metallic parts.

Wants A. L. A. M. Formula

Editor THE AUTOMOBILE:

[2,923]—Would you kindly inform me the method used to rate the horsepower of gas engines given by the A. L. A. M.

RALPH G. HISSEY.

Cape Cottage, Me.

The A. L. A. M. formula is as follows: $\frac{D^2 N}{2.5}$ where D is the diameter of the cylinder and N is the number of cylinders.

Using Worn Piston Rings

Editor THE AUTOMOBILE:

[2,924]—I believe I read somewhere that it would be possible to use worn piston rings for a time by inserting something beneath them to hold them out. Could you tell me how this is done?

OLD SUBSCRIBER.

Tenafly, N. J.

It has been done by inserting a small winding of hemp twine in the ring aperture. The winding of hemp is placed in the groove as shown in Fig. 3 and the ring placed back over it. The ends of the ring will be spread a little farther apart than formerly as seen in Fig. 4. This will hold for several months if properly done.

Has Elusive Misfire

Editor THE AUTOMOBILE:

[2,925]—I have a 40-horsepower car which I have driven until recently without experiencing any ignition troubles. Now, however, the engine has started misfiring. I have ground in all the valves, both intake and exhaust, and have had the cylinders off and cleaned the carbon out but without effect. The wiring has also all been completely examined in the hopes of locating the miss, but without success. The motor does not seem to misfire so much when running light and in the first and second speeds, but as soon as I go into high it will miss considerably.

At other times, when in high speed it will run 20 miles without a single miss. I am using dry batteries for ignition purposes, six cells connected in series. I am sure it is not due to the batteries, however, as the same thing occurs when I am using new batteries. Anything you may suggest which might help will be greatly appreciated by me. L. P. BEERY.

Thurston, O.

An elusive misfire is often due to the fact that the rotor of the timer has become loose on its shaft and changes its relative position. The misfiring is often accompanied by preignition and backfiring when this is the cause of the trouble. The spark plug may be sooty. Induction coil troubles are often responsible for just such a condition; there may be dirt between the contact points, the contact points may be loose, the connections within the coil box may be loose or the insulation within the coil box may be defective. The timer is often unsuspected when it is the seat of trouble; for instance, the contact points may be dirty, bad contact on account of worn or dirty parts may be found, or the shaft may not have good contact with the metal of the motor owing to the presence of a film of grease which partially insulates the shaft.

The battery cells will often shake about in such a manner that the electric connections between them are severed or at least rendered very uncertain. In this case it often happens that an irregular misfire is often developed. It is in this latter that the source of trouble will most likely be found. If these fail, carefully examine the carbureter for dirt.

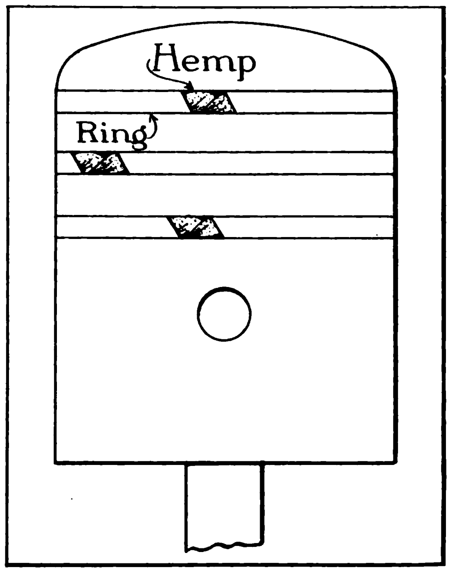

Fig. 4—Showing the appearance of the piston after the hemp is inserted

Query About Carbureters

Editor THE AUTOMOBILE:

[2,926]—I have a 25-horsepower car, and it may be all right, but I cannot help tinkering with the carbureter, which does not seem to be capable of giving satisfaction. I have had the obstinate thing treated by a repairman, but this has made things no better, and I am tired of it.

I have heard about several types of automatic carbureters, and I understand that these have a fixed nozzle opening, thus protecting the most delicate portion of the ravings of the driver. Where can I get a description of an up-to-date automatic carbureter?

Port Jervis, N. Y. WM. J. NUTTY.

On p. 822 of the issue of Nov. 9 is described an automatic type of carbureter, in which a fixed gasoline inlet is used, while the air supply varies with the demand of the motor. Another type of automatic carbureter was described in THE AUTOMOBILE of August 17.

Little Bits of Motor Wisdom

Tools and Other Devices Useful to Repairman and Driver

USING DIFFERENTIAL PULLEYS—Few of the smaller garages and repair shops realize the importance of the pulley system illustrated in Fig. 1 as a labor saver. Its principal use, as far as the repairman is concerned, is in connection with the removal of the motor from the chassis. Every garage should have a special place for such work to be done, and a heavy wrought iron hook or loop should be securely fastened in the ceiling at this point for the purpose of suspending the pulleys. When the nature of the repair necessitates the taking down of the motor, the car should be run to this particular part of the shop, and after taking out the holding bolts and other connections with the body of the machine, the differential pulleys should be brought into play to lift the motor onto the "horse" or bench provided for the purpose.

A good form of motor "horse," and one which is used by some of the larger repair shops, has two small wheels fixed to two of its legs, with handles at the other end. After placing a motor on it, it is wheeled to a lighter and more convenient place. In making the finer motor adjustments it is advisable to have as much daylight as possible, since better results can be expected from the mechanic who has a light and properly ventilated place to work. Very often a dull, besmeared incandescent lamp furnishes the only light the workman has at his command, and small wonder is it that with such facilities a motor which calls for accurate repair frequently leaves the shop practically in worse shape than when it entered.

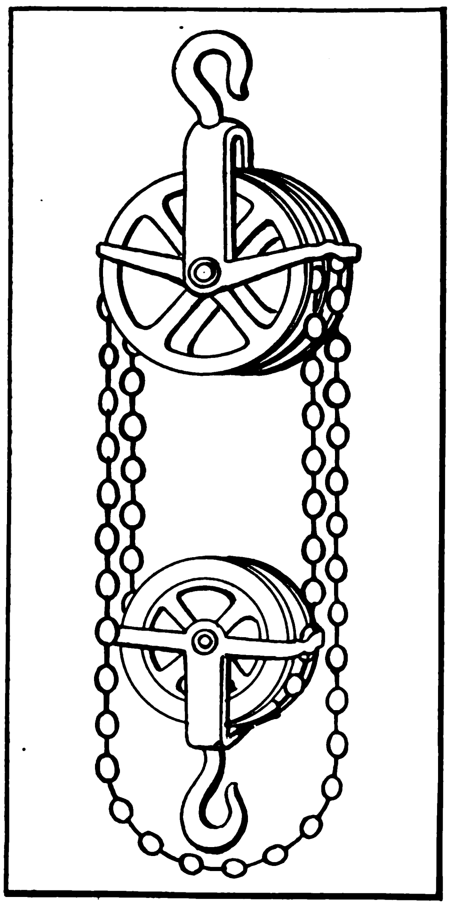

Fig. 1—Differential pulleys for lifting motors and other heavy parts

Nut Locking Devices.—Most motorists are familiar with the various methods in vogue for securing nuts on their bolt-ends so that the jarring and vibration to which they are subjected will not cause them to work loose or be lost. Sometimes two nuts are used, jamming against one another and locking in this way, the smaller or check nut being placed under the thicker regular one. This is not so good as the use of cotter pins, which are put through holes drilled in the ends of the bolts, and their ends spread to prevent their slipping out. This fastening prevents the loss of the nut, but does not do away with its tendency to turn.

Castellated nuts are used extensively for automobile work, and they afford the best method of fastening, since turning and loosening are both prevented. Fig. 2 shows the nut A with the cotter-pin C passing through the end of the bolt B. Diagonal slots are cut in the top of the nut, and the cotter rests in one of them. Of course, one of the slots must register with the drilled hole in the end of the bolt before the cotter can be put in place. Whenever possible, it is best to use this form of fastening.

Requirements of a Good Clutch—The life of a car is entirely in the hands of its driver. To prolong the life of the car is or should be the object of every driver, and to do this few things are so important as the proper manipulation of the clutch. A clutch should engage gradually; that is, it should not take up with a jerk, but should impart the motion of the motor to the car gradually, so that there are no undue strains upon the driving mechanism. It often happens also with a fierce clutch that the weight of the car is suddenly thrown upon the engine while it is running slowly, and the inertia is sufficient to stop the motor. A feature of a good clutch which may be said to be second in importance after gradual engagement is that it should disengage almost instantaneously so that there will be no drag.

The clutch generally performs its work by friction, hence a large surface is a beneficial feature inasmuch as the friction depends directly upon the area of contact between the surfaces. It is evident that if the surface is not large enough the clutch will slip, or, if it does not slip, a greater strain will be put on each unit of its surface and the life will be much shortened.

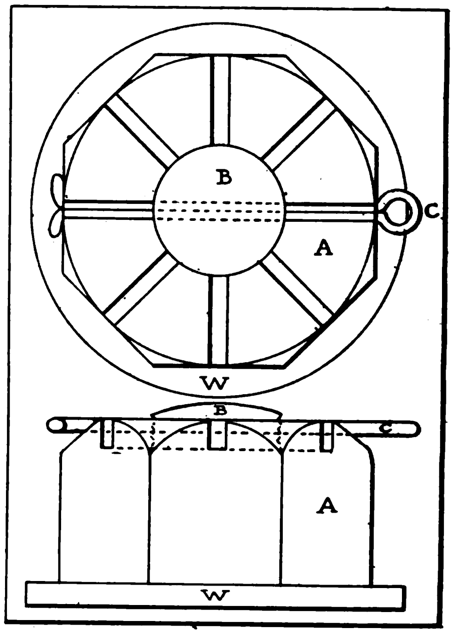

Fig. 2—Castellated nut with cotter-pin in place

The other requirements of a good clutch are the same as those of any piece of mechanism; that is, it should be capable of being inspected for wear or other defects in as simple a manner as possible. It should also be capable of adjustment so that if a slight amount of wear has taken place it will not be necessary to purchase an entirely new part, but that compensation may be made for any wear that does take place. The clutch should be simply and substantially constructed so that there is as little to get out of order as possible.

The friction member is sure to need replacement after the clutch has been in use for some time, and for this reason it should be placed upon the clutch in such a manner that it is very readily removed and refitted without disturbing any of the other parts. These requirements are for any of the friction clutches.

PLIERS OF DIFFERENT TYPES.—There are few who have not some type of wire pliers in the tool kit of their machine. It is doubtless well known that these tools are made in different styles to suit the different purposes for which pliers are used. In Fig. 3 are illustrated four different types of pliers which are of use to the automobilist who finds it necessary at times to perform some work about the electric wiring on his car.

The type numbered 1 in the illustration is about as familiar as any of the varieties of this most useful tool, and is so shaped that it is possible to obtain a firm hold upon the wire and at the same time, if so desired, the wire may be bent back and forth with pliers so that it is broken off at the edge of the tool. If it is desired to coil the wire for a short distance the wire is held in the pliers and they are turned around in the hand. This will produce a spiral in the wire.

The pliers shown at 2 are of entirely different shape, being so arranged that the wire will pass through the corrugated opening. The corrugations are arranged at such a distance apart that when the pliers are closed over the wire a very firm bite will result. In case it is desired to break the wire, all that it is necessary to do is to take hold of the wire with the end of the pliers instead of simply allowing the wire to pass through the corrugated teeth. The wire is then bent back and forth in the same manner as described for the flat pliers. A form of the tool somewhat similar to the type shown at 2 is illustrated at 3, the difference lying mainly in the blunt end.

The corrugations are also a feature of the pliers illustrated at 4; in this case, however, there are two sets of teeth to allow of the pliers being used with different sizes of wire. To break the wire the process is the same, consisting of seizing the wire in the end of the pliers and bending it until the break is made. If one of these varieties is chosen to have a place in the repair kit it will be sufficient, as any of the types may be used with entire satisfaction, although a combined cutter and plier would be even better.

HEADS OF DIFFERENT SHAPE.—Bolts, studs and screws are made with heads of different shape to accommodate them to the various usages to which they are to be put. In choosing the head required for different purposes, strength, weight, cost and appearance are all factors, but the governing feature which should determine the matter lies in the requirement of accessibility and convenience. There are many places about an automobile engine, for instance, where it is impossible to go with a wrench and yet a screwdriver could reach the desired spot very easily. In many cases of this kind, where a bolt has been made use of, a slot can be put in the head to take the screwdriver should it suit the convenience of the operator.

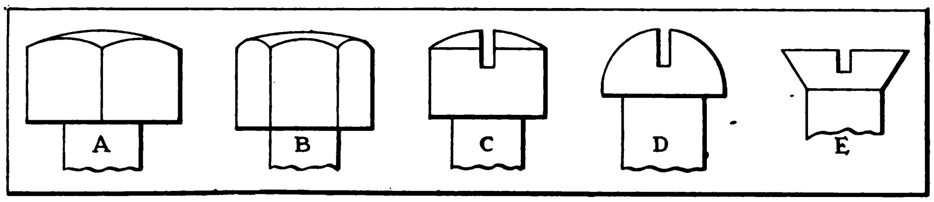

Fig. 4—Bolt, stud and screw heads are of various forms for different purposes

In Fig. 4 are shown five different types of heads used in connection with bolts, studs and screws. These five different types offer a wide enough choice to fulfill the requirements for convenience and appearance in any circumstances which may arise.

The head shown at A is square and may be used in connection with either a throughbolt or a stud. It has the advantage that the wrench is not prone to slip around it and wear the nut into a circle. This advantage is particularly felt in the smaller sizes of nuts where it is possible, by attempting to turn the nut with a wrench which is slightly too large, to spoil it to such an extent that it is exceedingly difficult to remove it at all. It is a great mistake to attempt to remove a nut with an over-sized wrench, since it is always possible, by the insertion of a flat piece of metal between the wrench and the nut to secure the same turning effect as if the wrench were the correct size, and at the same time none of the evils of a wrench which is too large are felt.

The hexagonal head is shown at B, and is common enough to need but few words to describe it. It has the great advantage that it is always turned in such a manner that it is possible to put the wrench over it to either tighten or loosen it. This advantage is not always possessed by the square head, as this may be turned in such a way that it is impossible to reach it with a wrench owing to the cramped surroundings. In such cases, however, even the hexagonal head will be found rather difficult to get at and the swings which can be made with the wrench will be so small that the operation of turning the nut will be both arduous and long.

It is in a case of the latter kind that the flat-headed machine screw is called into use, that is if the size of the stud be not over ½ inch. Where this head is used it is generally found that the metal is countersunk so that the head of the screw is just flush with the outside of the metal. This serves to give a neat appearance and a very workmanlike job. A screwdriver is a much better instrument for reaching inaccessible spots than is a wrench of any type, and it is for this reason that these screws should be used where the space prohibits the convenient use of nuts.

Where the head of the screw is to remain outside the surface of the metal, that is in cases where a countersunk head is not permissible, a better appearance is given the work by employing the round-headed screw as shown at D. The difference between this and the countersunk head screw lies merely in the appearance, the usages being the same. The head shown in the illustration at E is used almost entirely for wood-working operations. The countersink is for the purpose of improving the appearance of the finished work. In very fine work where the best possible appearance is made an aim the countersink is made extra deep so that the screws may be sunk considerably below the surface level, and then a plug of wood similar to the rest of the work is placed over it.

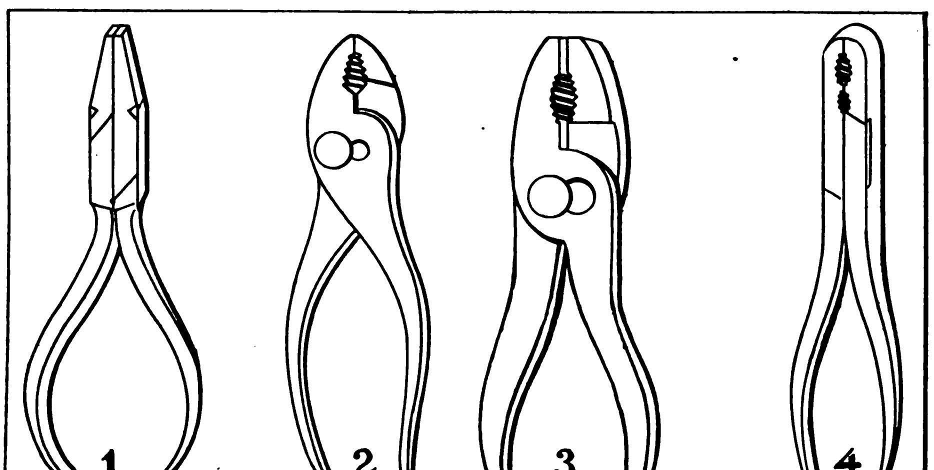

Fig. 3—Illustrating four typical varieties of pliers found in common use

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

Using Old Casings

EDITOR THE AUTOMOBILE:

When the ordinary automobile tire has pounded, skidded and ground over about 3,000 miles of common roads its condition insures an almost endless run of trouble and expense. The tire does not seem so badly worn that one feels justified in throwing it away, yet the frequent repairs together with the number of ruined inner tubes, and the consequent damage to one's moral character, certainly make it a paying proposition.

There is one way to get one-half as much more wear out of such casings without any expense to speak of. But in order to do this the plan which I am about to describe must be followed to the letter or results will not be satisfactory.

The plan consists in using one partially worn casing for a tread for another worn casing of the same size.

The casing which has the least rim cuts and injury near the beads should be selected for the inner one, and the one with the best tread should be selected for the outer.

If there are any breaks or holes in the

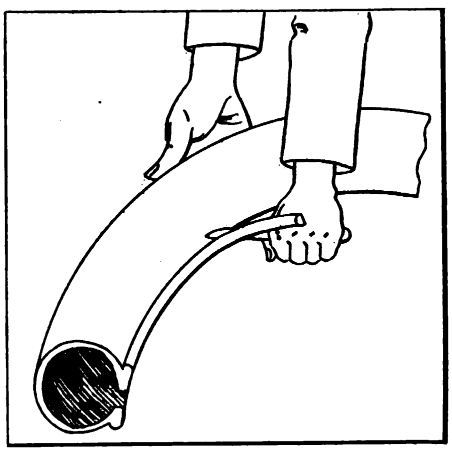

Fig. 1.—Depicting the operation of cutting the bead from the tire casing

fabric of the casing which is to be attached to the rim, they should be fairly well re-inforced with rubberized canvas inside patches, so as to offer a smooth surfacc to the inner tube.

The outside of this casing should then be well cleaned with gasolene, using an ordinary scrubbing brush and soft cloth for the work.

The old casing to be used for a tread should then be cleaned with gasolene on the inside, and the beads be cut off with a sharp knife.

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyse your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

With the other casing on the rim, but deflated, the tread casing is worked on over the surface, using an ordinary tire tool as a lever.

After it has been adjusted evenly in place, vulcanizing cement, in quantities of about one teaspoonful for each place, should be poured between the casings opposite every second spoke of the wheel, and with the fingers inserted between the casings; the cement should be distributed for some little distance each way.

The tire should then be pumped up to proper capacity and left unused for twelve hours to dry.

An old casing with the beads removed will have just enough elastic give to its fabric to afford a snug and supporting fit for another casing of the same dimensions with the beads retained. The tread thus applied will cost practically nothing, and will give a resistance to road wear that will fully equal half the value of a new tire.

It makes a particularly good tire for Winter use, as the tread is wider and flatter than a new tire.

It is less liable to ordinary puncture than a new tire, as it is almost double the thickness on the tread.

A good plan is to get new tires of 1-2-inch extra diameter for rear wheels, and use the old rear casings to re-tread the front tires.

In the Winter, when repairing tires and tubes on the road is anything but pleasant, this arrangement gives satisfactory results.

One thing should be remembered in connection with old casings. The beads, whether clincher or Dunlop style, stretch a little in use, and the effect is to render "pinching" of the inner tube much more frequent than with new tires. This fact calls for greater care in having good protecting strips between the tube and rim.

An old inner tube which has been slit around its periphery and the valve removed will make a first-class protecting strip to prevent pinching.

The life length of a casing depends largely upon the firm adhesion of the fabrics to each other. When a tire is run not properly inflated the hinge-like bending of the fabrics is much greater than when pumped up to the proper pressure, and this constant bending tends to separate the fabrics and weaken the casing.

A little careful observation will enable a driver to tell at once when a tire goes

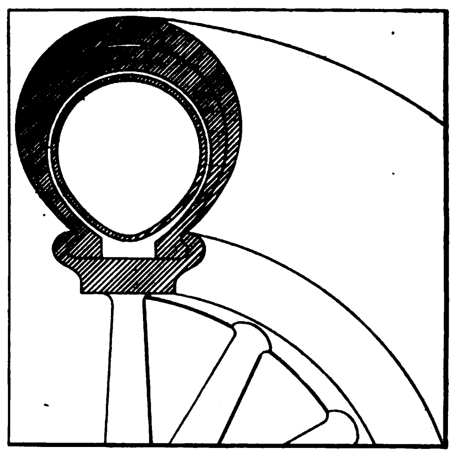

Fig. 2—The old casing A is fitted over the casing B in this manner

flat. And running on flat tires is very expensive.

The level of the front of the car will vary when one of the front tires deflates, and there will be a loss of speed when the rear tire lets go. If particular attention is given to these two ideas any careful driver will soon be able to stop his car immediately the tire goes flat on any wheel, and much expensive destruction of casings and inner tubes be avoided.

A. D. HARD, M. A.

Marshall, Minn.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Ideal a Lively Roadster

EDITOR THE AUTOMOBILE:

My ideal car for next year is a roadster that would have to step some. The motor would be four-cylinder, four-cycle, with the cylinders cast in pairs, and it would have a bore of 5 3-4 inches and a stroke of 8 inches. The cylinders would be of the T-head type with the valves on opposite sides, and they would be 3 1-4 inches in diameter at the bottom. The motor would have three large bearings, and the clutch would be of the large diameter cone type. The transmission would have four speeds ahead and reverse, with direct drive on third speed, and would be geared 1 1-2 to 1.

I would prefer a shaft to a chain drive, even in a car of this size. The rear axle would be a full floating type, and the brake drums would be about 14 inches in diameter with 4-inch faces. The car would have an underslung frame, with 36-inch wheels carrying 5 1-2-inch tires.

The engine would be equipped with a Remy magneto and a Schebler carbureter, and it would have an auxiliary air pump. The gasoline tank would be placed on the back along with the oil tank.

This car, with 124-inch wheelbase, equipped with glass front, speedometer and hand oil pump, ought to sell for $3000.

L. E. HOWE.

Liberty, Ind.

Wants Long Stroke Motor

Editor THE AUTOMOBILE:

The specifications of my ideal of a motor car should be as follows: Cylinder bore, 4 1-2 inches; stroke, 6 inches; six cylinders; four ball bearing crankshaft; cam shaft on left with four ball bearings; intake valve in the head; exhaust valve on left side; intake manifold at right side, water-jacketed; Rayfield carbureter with dash adjustment; force-feed oiling by gear pump with reservoir in the bottom of the crankcase; Bosch dual ignition system; honeycomb radiator with centrifugal pump; gasoline feed by gravity; self-starter using compressed air, with tank (which should also be used for filling tires) underneath the car; multiple-disc clutch, having 26 saw steel driving plates and 25 bronze driven plates, running in a bath of oil, four-speed transmission on roller bearings, with reverse; flywheel, clutch, transmission and motor in unit; rear axle of the full floating type on roller bearings; one universal joint back of the transmission, and another in front of the rear axle; front axle to be of I-beam construction, drop forged in one piece, and on roller bearings; cross rod behind the axle; steering gear of worm and wheel type, with spark and throttle levers at top of an 18-inch wheel; control levers at the right side; foot pedal at the right; clutch pedal at the left; button type accelerator; metal body, with wood frame; 10-inch upholstery; body of five-passenger torpedo type with cowl dash; control levers inside; 126-inch wheelbase; front wheels to have twelve spokes and rear to have fourteen, both 36 inches in diameter and to be made of second growth hickory; every other spoke of the rear wheels bolted to the brake drums; service brake to be internal expanding; 14 inches by 3 inches; emergency brake to be external contracting, 15 inches by 3 inches; both brakes to be lined with Thermoid; front springs to be semi-elliptic; rear springs to be three-quarter elliptic with grease cups at all bearings.

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic, to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

The accessories should include the following: Mohair top, windshield, Stewart speedometer, Gray and Davis electric lighting dynamo system, seat covers, trunk rack, quick-detachable demountable rims, battery and tool box on the left side, large enough to accommodate one inner tube, Klaxon horn, 36 x 4 tires, Truffault-Hartford shock absorbers.

The car as outlined should cost about $3000.

CARL H. ANDREAS.

St. Louis, Mo.

Has Criticisms to Offer.

Editor THE AUTOMOBILE:

I have read with intense interest the opinions of your readers regarding the specifications of the ideal car for the season of 1912. In my opinion the ideal car for any man is not governed so much by what he really thinks would be the best car which it is possible to construct, but would, on the contrary, be the best car which it is possible to build for the amount of money that the particular person may happen to have at his disposal for the purpose of purchasing an automobile.

There are many minor refinements which, while they are not a necessity, still add to the ease of running of the car or to its appearance to some slight extent, while the cost of their application to the car is far beyond the benefit to be reaped from their installation. The matter of wheel sizes is one of these cases where a large increase in cost arises from a slight increase in size; still every one is ready to admit the advantages of wheels of large diameter. Tire equipment in the first place will cost considerably more than would be the case with smaller wheels, and even though it be true that the wear on the tires will be correspondingly less, still at the same time this is not generally perceived by the purchaser of the car, who is not prone to consider the subsequent cost of upkeep when he first examines what he is getting for the amount of money he is laying out in purchasing his automobile.

There are numerous other details which enter into the problem of selecting an ideal car which, in my opinion, have been overlooked by those whose descriptions have been published in the pages of THE AUTOMOBILE, and among them there is the matter of body construction and appointments. It is all very well for the carping critic to say that the average automobile buyer will more often ask a question concerning the quality of the paint on the body than he will attempt to delve into the mysteries of the lubricating or ignition systems, but it must be admitted that there is a large amount of solid sense involved in the queries which are hurled at the head of the obliging automobile salesman. Fine feathers make fine birds in the automobile world as well as in the marts of the Parisian fashions, and the man who hands his last dollar over to the automobile concern whose wares have best satisfied his critical eye is justified to a large extent in clamoring for a beautiful appearance as well as a smooth-running motor.

Body finishing has advanced along with other departments of the game, and in my specifications of the ideal car I would include a few requirements regarding this part of the car and I think that my ideas do not clash with those of the majority of automobilists who go to make up that class known to the automobile trade as the average motorist.

J. P. HEWITT.

New York City.

Accessory Handling in Repair Shops

WHEN an automobile comes to the repair shop to be overhauled, thoroughly and well, from front to rear axle, the score of small accessories present on the car will have to be removed therefrom. This must be done to avoid such damage as will inevitably result from omitting this work. There is not a repairman or automobilist who would for a moment question the necessity of removing the accessories from the car. Clock, speedometer, odometer, lamps of all descriptions, and last but not least, tools, are too valuable to run the risk of breaking or losing them. If this should happen, it would of course mean double loss to the shop owner or manager; he would have to make reparation for the goods lost and a customer would be gone never to return.

In order to attain the end in the simplest way imaginable, the system used to insure owner and shop operator against the complication arising from disorder in this field will have to be as simple as it is efficacious. While the task of checking all small articles going off and on the car requires the attention of a conscientious and reliable worker, there is no need that he should be unusually bright or skilled. A boy will be able to attend to this end of the business, and there is nothing to bar him from a successful execution of his work. It is the practice in the large repair departments of New York City to have one boy do all the work of this kind, and superintendents are well satisfied with the success of the system.

When the car comes into the repair shop it is accompanied by a card bearing the name of the owner, the number of the car and a repair order number. The first two items are transferred to the head of the accessories card Fig. 1. Upon this card are entered all the accessories which have to be taken off the car, and the same is done with those parts which, for some reason or other, have to be removed, as was the case with the hub caps on Mr. Bigelow's car. The entries are made under the heading "In," and where it is not necessary to write numbers, a simple check will be made by the workman or boy. In most cases the articles printed on the sheet will cover the accessories which are thus handled, but when it comes to a speedometer, which does not originally appear on the form, the boy enters it on the sheet himself. There may be little objection to entering a speedometer under "Special Instrument," but a careful operator will always try to avoid any unclear statement on this card.

To each accessory, as it is taken off the car and entered on the card, a tag is attached, upon which the car owner's name, the car number and the number of the repair order are entered. Then all the accessories coming from one car are placed in a locker and its number is noted on the card, Fig. 1.

All the time the overhauling work is going on, the accessories remain in their own locker, undisturbed by the happenings in the repair shop. Only when the automobile is otherwise ready to leave the shop for its final test on the road the sundries are taken out of the locker and checked while this is being done. If, for some natural or supernatural reason, one or more of them has disappeared, the fact is noted on the card, as was the case with one of Mr. Bigelow's three oil-cans. (The card here shown has not been filled out in connection with an actual job, but only to illustrate its uses.) The operator who checks the accessories as they are taken out of the locker and replaced upon the automobile, signs his name on the card, which is

Shortage if Any

1 oil can

Locker #12.

Checked in by J. R. White Checked out by [illegible]

Fig. 1—All the small articles on an automobile are taken off and locked up while the car is being overhauled, and an exact record is kept of them

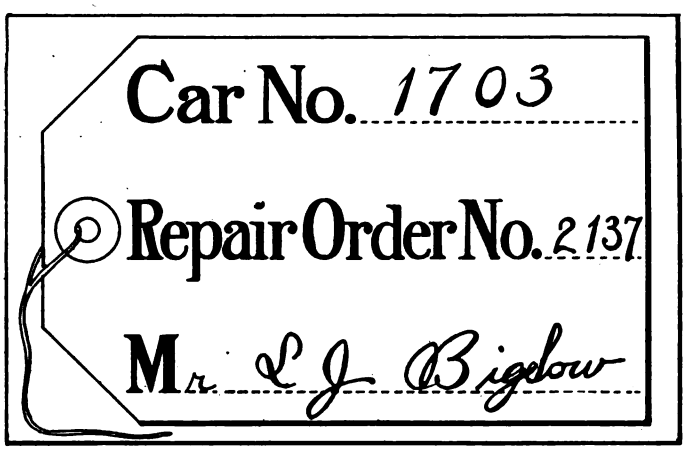

Fig. 2—To each article, be it a tire or a pair of goggles, is attached a tag giving all the necessary information relating to it

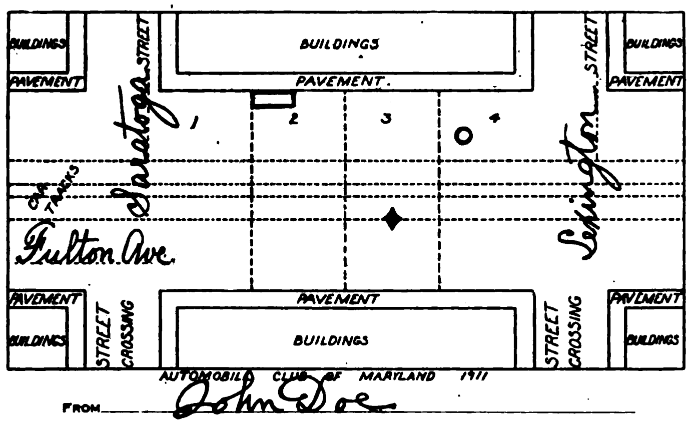
then transferred to the files of the repair department, where it is kept for any future reference that might become necessary. Whatever accessories are missing and cannot be found, are, of course, replaced.

The card illustrated is used in the repair department of the Peerless Motor Car Company, 1758 Broadway, New York City. Other concerns use somewhat different cards for the purpose of keeping track of accessories, but the variations are not fundamental. For instance, at the repair shops of the United Motor Company, Broadway and Sixty-first street, New York City, a very effective system has been introduced to help the concern to cope with the problems of the repair situation, but no special blanks are used for checking over accessories. The superintendent of the service department of this company is of the opinion that, with a reliable boy attending to the matter of checking accessories in and out, no special form is required. At the same time it is important that this work, consisting of a vast number of minor performances, should not be treated as a side issue by the worker, or chaos and consequent loss of efficiency and money will be the result. If the right sort of boy is used for the work, he will not be difficult to break in on it, and after a short time will be able to perform all his jobs with a minimum of control by the superintendent. After having introduced a system in handling the work in this department no repairman who means business has been known to discard the system. It is inexpensive to use, but too expensive to do without.

How the Maryland Club Watches Streets

BALTIMORE, MD., Nov. 20—At a recent meeting of the board of governors of the Automobile Club of Maryland the president appointed ten members to serve as a special committee on street repairs. This committee developed a plan for systematic notification of bad conditions in the streets of Baltimore which was heartily indorsed by the city engineer, Mr. H. K. McCay. A number of postal cards like that shown in the illustration, the reverse of which contain directions for indicating the location of holes, etc., in the paving, were sent to the club members to be filled out and mailed to the secretary. He turns them over to the city engineer as they come in, unless the trouble is within 2 feet of



Fac-simile of postal card issued to members by Automobile Club of Maryland.

Circle O indicates round, dangerous hole. Star ★ indicates sunken place in street, not necessarily dangerous. Oblong rectangle ▭ indicates trench or depression at right angles to the street. Paragraph ¶ indicates other conditions.

the car tracks, when he notifies the railway company. Sometimes, as in the example shown, the secretary finds conditions indicated for which both the city and the railway company are responsible. In this case he turns the card over to the city engineer and sends a notice to the railroad officials.

Another L. I. A. C. Contest

The contest for the Schimpf trophy proved so successful and the attendance was so encouraging that the contest committee of the Long Island Automobile Club has decided to hold a similar event on Saturday, November 25. It will be held under somewhat stricter rules than governed the competition for the Schimpf trophy and will be run over the 100-mile course.

The prize, which will be an automobile tire of any make and size desired by the winner, has been generously donated by Secretary Charles Hermann. The contest committee of the club consists of Edward Ashforth, William H. Kouwenhoven, Edward Melvin, William T. Wintringham and Frank G. Webb, chairman.

Calendar of Coming Events

Shows

Dec. 30-Jan. 6......Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (montaly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Metallurgy Made Easy

IN this issue THE AUTOMOBILE begins a series of articles on the subject Automobile Metallurgy Made Easy, which series will appear weekly covering a period of several months. The object of the series is explained in the title, namely, not only making easy the question of metallurgy but also imparting elementary knowledge of the different metals entering into the make-up of the modern automobile. A great deal of ignorance exists among the laity on the subject of metals. Many salesmen glibly use the terms nickel steel, vanadium steel, chrome nickel, tungsten, bessemer, open-hearth, etc., but how many know their meaning? How many know why they are used? How many can explain why the tensile strength factor is so important in the metal entering into one part of a car and yet not important in some other parts? In the textile world a man knows that cotton clothing does not constitute a good protection against cold. He knows that cotton is suitable for Summer wear, but that wool is best for cold weather. In the food field it is a well-understood fact that fats and oils are excellent for cold weather, but bad for use in Summer or for those who take little outdoor exercise. So it is in many of the other departments of life in which people are interested, but when it comes to the problem of the metals entering into an automobile and their why and wherefore, a new question suddenly arises. It is with the hope of imparting some practical information of this character that this series has been started. The series is for the car owner, the car dealer, the salesman and the laity in general. The series is not intended for the engineer, or the metallurgist. It is too elementary for them. The series is intended to serve as an alphabet of metals, a short series of brief stories on the qualities that metals must possess in order to be useful in the different parts of the automobile.

The series opens with five articles on the qualities specified for all steels, namely, tensile strength, elastic limit, elongation, torsion and the many vibrational strains. Following this the different kinds of steels will be treated, low-carbon steels, high-carbon steels, nickel steels and other grades such as chrome nickel, vanadium, titanium, bessemer, open hearth, crucible, electric, forged steel, rolled steel, pressed steel and steel castings, the last four referring to operations of manufacturing steels into parts intended for automobile uses. The series will continue along this line, including cast iron, cast brass, cast bronze, cast aluminum, steel castings and malleable iron castings. The bearing metals, such as phosphor bronze, white brass or bronze, babbitt and die-cast bushings, will receive attention. The entire scope of the series is such as to give the car owner who does not understand metallurgy a good general conception of the many metals; to give him a conception at least of why a certain metal is necessary in a certain part of a car so that he will be able to intelligently discuss metals and their uses when purchasing a machine.

To those whom these articles do not satisfy additional information will be furnished. All that is necessary is to write your wishes and mail them to the Editor. Sign your name and address legibly. They will both be used in conjunction with your communication. This series is for the layman and he is invited to open discussions, ask questions, etc. The series should be of special value to the dealer, the repairman and the salesman. Many of these have never been inside a factory, a foundry or a heat-treating room, so that the articles appearing will serve as an elementary course of information along a line which is daily growing in importance.

* * *

The Accessible Car

ATTENTION was drawn to accessibility in these pages some weeks ago, the chief reason advanced for it being that it reduces the cost of car operation and so administers to the general good of the cause. Since then the foreign makers have exhibited their 1912 wares to the public at the great Olympia show, and it is interesting to see how much advancement they are making along this matter of accessibility. One foreign engineer, in speaking on the subject of accessibility, mentioned the two broad phases of accessibility that should be kept in mind, namely: First, accessibility in the matter of those parts of the car that require more or less attention from the driver when on the road or in the garage at the end of a day's run; and second, that constructive accessibility which exhibits itself when a car is delivered to the repairman to have such parts as differential, clutch or gearbox overhauled or repaired.

The first class of accessibility has to do chiefly with the owner and driver. It incorporates such features as brake adjustments, which can be used without twisting the arm L-fashion around springs, shock absorbers, fenders and axle parts; it applies to the location of grease-cups, which can be reached without covering the coat sleeve with grease; it applies to the carrying of tools, which are so placed as to be obtained without getting anybody out of the car; it applies to that axle design which allows placing a jack under the front or rear axle and elevating either without having to spend a long time; it applies to the carbureter location in which the shutter-valve, for starting, the air valve or needle valve adjustments are reached without having to put on an elbow-glove; it applies to those lubricating features in which it is possible to drain the old oil out of the crankcase without getting under the car to open a petcock in the base of the crankcase; it applies to those oil-filling designs which permit of pouring in oil from an ordinary gallon can without spilling a goodly portion over the motor parts; it applies to those magneto fastenings which allow of removing the magneto in less than 5 minutes and of replacing it in an equally short time—there are some makes in which it takes over an hour to remove the magneto. In a word, it applies to all such parts of a car as require attention either for the purpose of lubrication or adjustment.

The second accessibility is that which saves money when the car is placed in the repair shop. If the differential unit has to be removed, it should be removable through the opening in the differential housing. In some cars the entire axle has to be detached from the car, the axle sleeves removed from the housing and other disassembly carried out. This is very expensive; it means hours of work by the repairman. If the clutch has to be removed it should be removable without having to take off the gear box or loosen the motor from its supports. Time saved means money saved in this field. So it is if the lower bearings of the connecting-rods have to be taken up; if the carbon has to be taken out of the cylinder-heads; if the piston-rings have to be replaced; if a cylinder casting has to be removed; or if a radiator has to be taken off. A buyer should look to this matter of accessibility in buying a car. With the approach of the show circuit he should study the big problem of accessibility; it will mean money saved to him after buying the car, providing the automobile which he purchases is of as good material and workmanship as the less accessible one.

Coffin Addresses British Engineers

LONDON, Nov. 15—Howard E. Coffin, past president of the Society of Automobile Engineers delivered one of the feature addresses presented to the joint session of the Institution of Automobile Engineers and the S. A. E. held here. The joint convention was attended by about sixty members of the American society and was marked by most cordial relations between the British hosts and their visitors.

Mr. Coffin's remarks were in part as follows:

A comparison of the engineering practice entering into the better class of American cars does not show any greater degree of uniformity than is to be found in the similar class of English cars. Various spring suspensions are to be found; single and double-jointed cardan shafts are in evidence; some rear constructions are fitted with a torque-absorbing member and some are not; the drive of the road wheels is transmitted to the main frame through the springs, through radius rods or through a tubular housing for the propeller or cardan shaft, etc., as may suit the whim, the pet theory or the necessities of the individual designer.

High-powered motors are a necessity, first, because of the excess of brute power required to negotiate the poorer class of roads at speed; and, second, because of the antipathy of the average American towards the use of the gear-shift lever.

As nearly as can be judged at the moment, the coming of the long stroke will mean no lessening of bores—merely an increase in powers. A six-cylinder car, for instance, formerly 5x5½ inches in bore and stroke, will for this year be 5x7. Four-inch engines are moving up from 4x4½ to 4x5, 4x5½ and even 4x6, with no very great changes otherwise in the chassis or weight of the finished car. The low price of fuel and the low rate of or total absence of horsepower taxation tend to encourage rather than discourage this advance in power. A broad statement may almost be made, that no American car above the smallest two-seater will carry a four-cylinder motor of less than 4-inch bore. One or two instances, such as the Hupmobile, may be said to be the exceptions which prove the rule.

Another peculiarity often remarked by those from this side of the water is the brake location. Double brakes upon the rear wheels have become an almost universal practice. Almost every argument in the category can be cited in favor of the cardan shaft service brake. European precedent is a unit for it.

The character of American roads and the conditions under which American cars are forced to perform have had necessarily a great influence upon the direction of detail development. Road clearances, spring lengths and spring clearances, the avoidance of extreme lengths in wheelbase, precautionary measures against squeaks and rattles through leather and rubber liners, bronze bushings, numerous grease cups, etc., the deep ribbing or beading of all sheet-metal surfaces for the prevention of vibration, the secure locking of every bolt and nut in its place, these and a hundred and one other of the things are being given a particular attention because of the nature of the service to be encountered at the hands of the American user.

American cars, and hence American standards of motor engineering, were for years regarded as somewhat of a joke upon this side of the water. But because American design differs from those principles which have been found to succeed in Europe, it must not be assumed that the American designer is ignorant as to the trend of practice upon this side of the water. The light, high-speed, small-bore motor of 12 to 15 horsepower would perform admirably upon the English-like roads of New England, but would fail miserably in the face of the hub-deep, sticky gumbo of some sections of the Middle West.

Ample road clearance is an absolute necessity upon any car which is built in quantity to meet a nation-wide market in the states. Hence larger wheels, greater axle and flywheel ground clearance, and a generally somewhat higher car appearance than is usual upon this side.

Few cars of any power or price will go into the next season without self-starting motors. Several are already fitting starters as regular equipment for this season, and many others are following suit.

Next the lighting problem. Six months ago it looked like a walkaway for the electric generating outfit. But the fears of electric competition have brought gas lamp improvements, whereby one may, with a single switch turning movement from the seat, turn on and light the acetylene gas lamps. The use of the acetylene self-starter also would seem to argue well for the retention of the gas light in combination.

As to en bloc castings and the protection of working parts, I do not believe that the newer American cars will be found to differ greatly from European practice.

I already have mentioned one or two chassis peculiarities. To these I might add the frequent positioning of the gear box upon the rear axle member. I presume that the arguments pro and con upon this subject are much the same with you as with us—weight and tire wear upon one side and gear quietness with manufacturing and repair advantages upon the other.

No engineering discussion would just now be complete without some mention of special motor valves. The Knight motor you know. It is now being adopted by four makers in the states, and apparently with success. There are several American valve mechanisms which seem to promise well. Every one is of the rotary disk or rotary valve type. It seems to be the American creed that if the poppet valve is dropped, it would be a mistake to replace it with another reciprocating mechanism—sleeve or otherwise.

It is not to be expected that the coming annual show in January in New York will bring out any marked change in clutch construction. The cone probably will show a percentage of increase, not because the disk and other types are being abandoned, but because a larger number of the newer and cheaper models will carry the cone as the cheapest form of the reasonably satisfactory clutch. There is one form of clutch coming into use in the states which is, I believe, entirely unknown upon this side of the water. I refer to the multiple-disk form using cork for the friction surface. I will make the broad statement that the properly constructed cork-surfaced clutch will distance all others in smoothness of action, length of service and freedom from trouble both in the factory and upon the road.

Power tire pumps are being fitted to many of the higher and medium-priced cars—the demountable rim may be said to be becoming almost the regular equipment of all but the very cheapest machines.

There is a marked tendency toward the use of roller bearings of which several makes are well known in the states.

Demountable wheels—wood—have been for several years fitted as regular equipment by one of our American makers. It does not seem probable that this practice will spread. Wire wheels have lost favor and in 1903 and 1904, when the good public made up its mind in favor of wooden spokes, American manufacturers were forced to scrap thousands of sets of wire equipment because the turn of the tide came so suddenly.

There can be no better school of design than the racing camp during the 2 weeks' practice period just before some big 200 or 300-mile road race. But here, as in every other line, a definite system must be followed if the best returns in an engineering as well as a publicity way are to be had.

A not unusual method of procedure is to place the chief engineer either directly in charge of the contest work or at least in close working contact with contest crew management. A crew is more than frequently made up of a business manager and from two to three cars with drivers and mechanics. If the engineer is wise he will have placed upon his desk an almost daily detailed report of the performance and troubles of these contest cars. I don't know of a more searching trial of steering connections, wheels, motors and, in short, of the entire driving mechanism than is the 300-mile road race or the 2,000-mile endurance run covering every possible road condition.

The encouragement of the stock car contest has been of unusual value to the engineer and hence to the progress of the industry in the states. Not only has the American engineer been constantly able to judge of the performance of standard cars under severe service conditions, but he has been no less the gainer in that he has had his whole attention riveted upon a bread and butter model, rather than upon some monster racing car.

Just now we are hearing much over here of the American invasion of the English market. There seems to be a good deal of worry, at least upon the part of the press. I don't quite see why England fears an invasion. The invasion is of the cheap car, I believe it is called. If the cheap car has a field in England, the probabilities are that it is a field to which you have not yourselves catered. It seems to me that you may meet the issue either by building low-priced cars yourselves for this demand or by keeping out of this field and sticking to the class of product to which your preferences and your methods incline you. We have been through the same thing in America exactly. The production of the $500 car by Ford was croaked to be the death knell of all high price getting. There have been several death knells since Ford, and Ford himself is still at it to the tune of 75,000 cars for 1912.

General Motors Reports Good Year

NET profits amounting to $4,066,251.31 were made by the General Motors Company during the 10 months preceding July 31, 1911, according to the first annual statement of that organization since the flotation of its $15,000,000 bond issue a year ago. The period covered by the report is not a full year because the fiscal year of the company now ends July 31 in place of October 1, as heretofore. After deducting $750,000 interest on the bond issue; $506,226 for the April dividend and making a proportional reservation for the October dividend, there remained $2,474,176.98 as undivided profits.

The bonded indebtedness has been reduced to $13,454,000 by the retirement of $1,546,000 of the bonds.

During the year it was decided to write off and reduce some of the inventories taken October 1, 1910, and this has been done to the extent of $2,000,000, thus leaving the surplus of the company at $1,240,175.26.

Under the financial plans of the company $1,500,000 will be retired in 1912 and $2,000,000 in 1913 and 1914 respectively. The remainder of the bonds will mature the following year.

The total net working capital of the corporation, according to the report is $23,065,353.20, or practically $10,000,000 over its bonds. During the period covered capital expenditures for permanent improvements, largely the purchase of land, building and equipment to extend the Cadillac plant, amounted to $1,803,030.68.

President Neal says that all the factories included in the properties of General Motors were working practically at full capacity at the time the report was submitted to the directors, there having been a gradual resumption of activity.

Among the plans projected for the company is the perfection of a general staff of mechanical engineers, gasoline engine engineers, designers, production experts and other experts to advise with and assist the staffs of the various factories. The new laboratory under charge of the director of production has been elaborately equipped for testing materials and preventing factory errors. The General Motors Export Company, to sell the corporation's products abroad proposes to make Bedford Motors Limited of London its distributing branch for continental Europe. The General Motors Truck Company has been organized to market the truck products of the company.

President Neal declares he is hopeful for the coming year and states that business is on a satisfactory basis.

The assets of General Motors amount to $54,388,072.58 according to the report of Comptroller Magee.

The liabilities include stock issues of $60,215,830; bonds $14,002,000; current liabilities, $2,785,615.01 and cash surplus, $4,443,251.31. In the above, the item of bonds was reduced to $13,454,000 as of October 1, 1911.

During the past year the company has taken up $46,000 of its bonded debt in excess of requirements. The action of the directors in writing off $2,000,000 from the inventories submitted at the time the bonds were sold tends to improve the position of the company by making allowance for depreciation and possible overvaluation of assets. Of the twenty-one companies embraced in General Motors, the corporation owns a total of $14,611,003 of their stock issues out of a total of $16,114,003.

The report was favorably received by the trade, over which the financial situation of the company hung like a cloud prior to the successful flotation of the big bond issue in the Fall of 1910.

The retirement of $1,546,000 of the bonds during the first year of operation under the new financial plan will decrease interest payments by $92,760. If the regular course is followed in 1912, the interest charge will be further reduced by $90,000 and during 1913 and 1914 respectively, $120,000 will be cut off. Thus the charge for interest would be reduced from $750,000 a year as it was after the bonds were sold to $327,240.

The company has the right to retire any or all of the bonds before they are due at 102 1-2 and accrued interest.

The officers of the corporation at the date of the report were as follows: Thomas Neal, president; W. C. Durant, W. J. Mead, Emory W. Clark, vice-presidents; Standish Backus, secretary; James T. Shaw, treasurer and C. A. Magee, comptroller. The finance committee includes: Emory W. Clark, W. C. Durant, Andrew H. Green, Jr., and Edwin D. Metcalf.

Trucks in Mail Delivery Service

WASHINGTON, D. C., Nov. 20—Three Franklin motor buses with specially built bodies were placed in the delivery service of the city post office this week. The service is being handled by David S. Hendrick, agent for Franklin cars, who was awarded the contract for furnishing the service for a four-year period at the lump price of $74,000. The buses will make eight trips a day, four during the day shift from 7 a. m. to 4 p. m. and four from that hour to midnight. Each trip will be for collection service, but on the first three trips each day the carriers will be taken to points where their routes begin.

The idea of using motor service in this particular manner originated with Postmaster-General Frank Hitchcock, and if the service is a success here it is likely it will be extended elsewhere.

One-thousand-pound Franklin chassis are used to which have been fitted bodies built by McReynolds & Son. Seats are built in the interior of the buses, entrance being through the rear. There is also a rack for mail bags. The driver and one carrier are carried on the front seat, while there is ample room for eight carriers inside each bus.

Akron Tire Industry Increasing

AKRON, OHIO, Nov. 20—"Things are picking up and business is becoming more and more stable during the Winter season," says C. B. Raymond, secretary of the B. F. Goodrich Company. "We expect that the coming national election will have some effect on the rubber business as on all other lines of business, and consequently no immense supplies of raw material are being stored locally, and the finished product will be kept down pretty well to actual orders. But the demand itself is increasing and I look forward to a very good year in 1912 in spite of the election."

Akron rubber factories, all of which are centered largely upon the manufacture of tires, employ 17,000 workers. Plans now indicate that this number will be increased at least 2,000 during the Winter.

Development along various market lines is credited with the steady increase of the tire demand. For one thing, local manufacturers say, automobiles are being used more generally in the rural districts. Another reason is the more general use of automobiles in Winter as well as Summer. The third reason for Akron tire activities is the development of the motor truck.

Over Fifty Cars in Georgia State Tour

ATLANTA, GA., Nov. 20—A striking example of the trend of popular favor toward non-technical, nearly non-competitive automobile runs will be given by the tour around Georgia, which will start from Atlanta November 22 with certainly well over 50 automobiles in line.

That such a number of entries can be secured in a State where automobiles are not as numerous as they are in the Eastern States at a time when vacations are all over for a jaunt which will include six days of touring and five days at Savannah shows something of the popularity of near-sociability runs.

In this event there will be no technical requirements, 18 miles an hour will be the fastest speed required, contestants may run during the noon hour without having it counted in their running time and any repairs can be made at any time. If repairs are made while the cars are in controls it will not be charged against the cars. Under conditions of this sort the Tour Around Georgia has been able to secure a highly creditable list of entries.

The night stops of the tour will be Americus, Valdosta, Baxley, Savannah, Dublin and Atlanta. The officials chosen already are Joe Brown Connaly, referee; R. C. Clarke, starter, and P. H. Hammond, checker. Prizes amounting to $2,600 have been offered to be divided among the winners in the various classes.

The tourists will spend from the night of November 25 until the morning of December 1 in Savannah, where they will witness the running of the Vanderbilt, Grand Prize and lesser events.

More road preparations are being made for this tour perhaps than were ever made before for a State event. Signboards have been placed at all cross roads and will serve to mark a permanent ideal tour aroung Georgia. In Bullock and Emanuel counties three bridges have just been completed over streams that have given trouble in previous tours. In these counties and in Laurens new strips of road are just being finished especially for this tour and hundreds of convicts are toiling long hours on the final touches.

The Adrian-Scott cut-off in Johnson county is also being completed and will be in fine condition. Unless there is rain the tourists will have excellent going all the way from Atlanta back to Atlanta. Of course, under the conditions of the tour not all the competing cars will start from the Georgia capital but can pick up the tour at any control. All that is required is that they complete the entire circuit. However, most ot the contestants will come to the Gate City for the big getaway.

The entries up to November 18 were:

1—Atlanta Ad-Men's Club, Atlanta, Overland.
2—Ohio Motor Car Company, Cincinnati, Ohio, Ohio.
3—Dr. J. C. Luke, Ocilla, Ga., Ohio Motor Company's sales agent, Ohio.
4—Ohio Motor Car Company, Ocilla, Ga., sales agency, Ohio.
5—Jake W. Paulk, Ocilla, Ga., Ohio.
6—W. E. Sawyer, Americus, Overland.
7—S. C. Dunlap, Gainesville, E-M-F.
8—A. M. Kitchen, Cornelia, Ga., E-M-F.
9—Balkcom & Ricketson, Boston, Ga., E-M-F.
10—W. V. Kriegshaber, Atlanta, Chalmers.
11—Atlanta Chamber of Commerce, Cole.
12—H. B. Odell, Atlanta, Thomas, pacemaker.
13—W. D. Alexander, Atlanta, Dorris.
14—Miss Regina Rambo, Marietta, Ga., Overland.
15—T. C. Lauren, Atlanta, Packard.
16—Dr. B. L. Bridges, Ellaville, Ga., Buick.
17—George H. Fauss, Atlanta, Dorris.
18—M. Luke, Jr., Ocilla, Ga., Everitt.
19—Velie Motor Vehicle Company, Atlanta, Velie.
20—Velie Motor Vehicle Company, Atlanta, Velie, press car.
21—Frank G. Corker, Dublin, Ga., White Gas.
22—Sam Bashinski, Dublin, Ga., Chalmers.
23—Dolph Walker, Atlanta, National.
24—Marathon Motor Car Company, Nashville, Marathon, press car.
25—D. Woodward, Atlanta, Knox.
26—J. Leon Bell, Swainsboro, Ga., Cadillac.
27—N. E. McLeod, Swainsboro, Ga., Westcott.
28—U. S. Fuller, Culloden, Ga., Cadillac.
29—D. D. Armstrong, V. P. of T. C. A., Atlanta, Thomas.
30—Holmes Bros., Culloden, Ga., Buick.
31—W. A. Thacher, Decatur, Ga., Buick.
32—W. A. Thacher, Decatur, Ga., Buick.
33—E-M-F Company, Atlanta, G. W. Hanson, manager, Flanders.
34—E-M-F Company, Atlanta, G. W. Hanson, manager, Flanders.
35—E-M-F Company, Atlanta, G. W. Hanson, manager, Flanders.
36—G. W. Varn, Valdosta, Ga., Cadillac.
37—Evelyn Harris, Southern Bell Telephone Company, Thomas.
38—W. G. Sutherlin, Atlanta, Overland.
39—Marvin R. McClatchey, Atlanta, White Gas.
40—F. G. Edwards, Albany, Ga., Chalmers.
41—Robinson Neckwear Company, Atlanta, Marmon.
42—Councilman Steve R. Johnson, Atlanta, Buick.
43—W. B. Cummings, Chief Atlanta Fire Department, Buick.
44—St. Elmo Massengale, advertising agency, Atlanta, Garford.
45—Boyd Perry, Atlanta, Ohio.
46—Gulf Refining Company, Atlanta, Mitchell.
47—Henry Meinert, Marietta, Maxwell.
48—Georgia Motor Car Company, Atlanta, Liberty Brush.
49—Georgia Motor Car Company, Atlanta, Everitt.
50—Swann & Campbell, Covington, Ga., Buick.
51—Herbert C. White, DeWitt, Ga., Maxwell.
52—William J. Davis, Atlanta, Pope-Hartford.
53—Muckalee Cigar Company, Americus, Cliff Clay, Marmon.

Contest Board Denies Wishart's Plea

Denying the appeal of Spencer Wishart, who drove a Mercedes car into second place at the late Fairmount Park road race, suffering disqualification by the referee for failure to carry his mechanic in the latter part of the run, the Contest Board of A. A. A. upheld the ruling of the race official and placed a Lozier car driven by Mulford second in the big race and first in its class.

The board disqualified and suspended Edson Card, Jr., for an indefinite period for conducting an unsanctioned meeting on election day, but absolves the registered drivers from blame as they were led to believe the affair had official sanction.

Frank P. Fox, registered driver, was suspended for a year for participating in an unsanctioned hill climb. H. D. Fisher, suspended for incompetence at Brighton Beach, July 3, moved for reconsideration of his case, which was denied.

George H. Clark, registered driver, who was suspended for two years for competing in an unsanctioned race meeting at Los Angeles under the name of E. Z. Martin, failed to have the ban raised by the board.

Good Roads Advocates in Session

RICHMOND, VA., Nov. 23—The first annual road congress held under the auspices of the American Association for Highway Improvement opened Monday for a meeting to cover four days. President Taft was unable to be present as expected, the reason being a severe cold. The attendance was large and representative and several of the debates were spirited. President Logan Waller Page presided at the sessions, which were held in the auditorium of the Jefferson hotel.

Monday was national day; Tuesday, states day and to-day is road users' day. To-morrow will be the most important session of the convention embracing many interesting phases of the preceding days.

Hoosiers Plan Southern Tour

ATLANTA, GA., Nov. 20—John Orman, secretary of the Indianapolis Auto Dealers' Association, has been prospecting about the South for several weeks of late primarily for the Premier Motor Vehicle Company, but incidentally with a view of finding out how this section would do as the scene of the next I. A. D. A. run, which is planned for next Summer.

"The South is just getting ready for the higher-priced cars and it is in this section especially that the Indiana dealers will have to look to dispose of their cars," he said. "I shall advocate a run through Louisville and Nashville to Atlanta, then over to Birmingham and back home again."

Spaces Allotted for N.A.A.M. Shows

FINAL allotments of show space for the exhibition of the National Association of Automobile Manufacturers in the Grand Central Palace have been made. There are still a few spaces that have not been definitely filled, but there are also several applications on file from which a selection will be made within a few days.

The following named companies have been added to the list or have had their original space allotments changed in one way or another: Regal Motor Car Company, main floor, space G; Columbus Buggy Company, main floor, space J-2; Gramm Motor Truck Company, main floor, space M-1; Kelly Motor Truck Company, main floor, space M-2. On the second floor are the following: Chase Motor Truck Company, space A-3; Universal Motor Truck Company, A-4; Westcott Motor Car Company, A-5; L. J. Bergdoll Motor Company, A-6; King Motor Car Company, A-7; Metz Company, A-8; L. E. Schlotterback Manufacturing Company, B-1; Newark Auto Manufacturing Company, B-2; Velie Motor Vehicle Company, C-1; Bowling Green Motor Car Company, C-2; Progress Development Company, C-3; Vandewater and Company, Ltd., D-2; Veerac Sales Company, D-3; Atterbury Motor Car Company, E-2; A. O. Smith Company, F-2; Stuyvesant Motor Car Company, H-2; Federal Motor Truck Company, H-5; Herreshoff Motor Company, H-6; G. H. Bushnell Press Company, J-4; Atlantic Motor Truck Company, J-5; Motor Wagon Company, K-3; Decatur Motor Car Company, K-4; Dayton Auto Truck Company, L-1; Lauth-Juergens Motor Car Company, L-2; Argo Electric Vehicle Company, L-3 Dart Manufacturing Company, M-1.

The list of car exhibitors, as revised to date, follows:

AUTOMOBILES—FIRST FLOOR

A-2 Clarke-Carter Auto Co., Jackson, Mich.
A-3 Imperial Auto Co., Jackson, Mich.
A-4 Ohio Electric Car Co., Toledo, Ohio.
A-5 Velie Motor Vehicle Co., Moline, Ill.
A-6 Velie Motor Vehicle Co., Moline, Ill.
A-7 W. A. Paterson Co., Flint, Mich.
B Hupp Corporation, Detroit, Mich.
C-2 Paige-Detroit Motor Car Co., Detroit, Mich.
D Fiat Auto Co., 1776 Broadway, New York.
E-1 Marion Motor Sales Co., Indianapolis, Ind.
E-2 Ideal Motor Car Co., Indianapolis, Ind.
E-3 Krit Motor Car Co., Detroit, Mich.
F-1 Cole Motor Car Co., Indianapolis, Ind.
F-2 Hupp Motor Car Co., Detroit, Mich.
F-3 Warren Motor Car Co., Detroit, Mich.
G Regal Motor Car Co., Detroit, Mich.

N-2 Pennsylvania Rubber Co., Jeannette, Pa.
N-3 Remy Electric Co., Anderson, Ind.
N-4 Gemmer Mfg. Co., Detroit, Mich.
N-5 Stromberg Motor Devices Co., Chicago, Ill.

New Palace to Seat 4,000 More than Garden

Official announcement of a preliminary character with regard to the building of a big show structure in New York city was made Tuesday, when Manager Spratt, of the Grand Central Palace, declared that the new structure which will be built south of the present building on Lexington avenue will approximate in shape and size the present Madison Square Garden. It will differ from that building, however, in one very important particular as it will be arranged to seat about 4,000 more than the present structure.

The plans have been prepared and at present they are being presented to the New York Central Railroad for approval.

It is intended that the new building shall be ready for occupancy by next Fall.

The three floors of Grand Central Palace, which will be used for the N. A. A. M. show have a floor space of 128,000 square feet. The new building, according to report, but not officially, will have an exhibition space of about 100,000 square feet. It is intended to connect the two structures by bridged passageways, so that they will be made available for one great show in two sections.

One of these will be available for the passenger automobiles and accessories and the other for trucks and accessories. Even under those conditions, space would appear to be at a premium. This may be accounted for by the increasing size of the trucks and the more numerous models in the passenger car lines. The Garden as it is now will barely accommodate all the lines of trucks that seek admission to the annual automobile shows held there, and while it might be possible to conduct a show equal to both weeks of the coming Board of Trade exhibition in one week, it would be found difficult to take care of all the standard cars of American motordom in any building in the world. Thus, the probabilities of the future point to the holding of two distinct shows, each continuing for one week. If this is done, New York will have buildings ample in size and facilities for holding such exhibitions.

The Final Line-Up at the Chicago Show

OFFICIAL and final allotments for the Chicago automobile show passenger vehicle section, of the National Association of Automobile Manufacturers, contain the following changes and additions: Warren Motor Car Company, First Regiment Armory, space G-1; Flanders Manufacturing Company, H-1. Coliseum basement: Westcott Motor Car Company, 2; Crow Motor Car Company, 3; L. J. Bergdoll Motor Company, 7; Colby Motor Company, 11; Lexington Motor Car Company, 12; Standard Electric Car Company, 14; King Motor Car Company, 16; George W. Davis Carriage Company, 17.

The complete list of exhibitors for the first week follows:

COLISEUM—AUTOMOBILES

A-1 Winton Motor Carriage Co., Cleveland, Ohio.
A-2 Thomas B. Jeffery Co., Kenosha, Wis.
A-3 H. H. Franklin Mfg. Co., Syracuse, N. Y.
A-4 Buick Motor Co., Flint, Mich.
A-5 Nordyke & Marmon Co., Indianapolis, Ind.
A-6 E-M-F Company, Detroit, Mich.
B-1 Woods Motor Vehicle Co., Chicago, Ill.
B-2 Locomobile Co. of America, Bridgeport, Conn.
B-3 Lozier Motor Co., Detroit, Mich.
B-4 Hudson Motor Car Co., Detroit, Mich.
B-5 Reo Motor Car Co., Lansing, Mich.
B-6 Olds Motor Works, Lansing, Mich.
C-1 Packard Motor Car Co., Detroit, Mich.
C-2 Pierce Arrow Motor Car Co., Buffalo, N. Y.
C-3 Stevens-Duryea Co., Chicopee Falls, Mass.
C-4 Chalmers Motor Co., Detroit, Mich.
C-5 National Motor Vehicle Co., Indianapolis, Ind.
C-6 Pope Mfg. Co., Hartford, Conn.
D-1 Maxwell-Briscoe Motor Co., New York.
D-2 Dayton Motor Car Co., Dayton, Ohio.
D-3 Premier Motor Mfg. Co., Indianapolis, Ind.
D-4 Cadillac Motor Car Co., Detroit, Mich.
D-5 Willys-Overland Co., Toledo, Ohio.
D-6 Peerless Motor Car Co., Cleveland, Ohio.
E-1 Brush Runabout Co., Detroit, Mich.
E-2 E. R. Thomas Motor Car Co., Buffalo, N. Y.
E-3 Pullman Motor Car Co., York, Pa.
E-4 Knox Automobile Co., Springfield, Mass.
F-1 Columbia Motor Car Co., Hartford, Conn.
F-2 White Company, Cleveland, Ohio.
F-3 Haynes Automobile Co., Kokomo, Ind.
F-4 Corbin Motor Vehicle Corp., New Britain, Conn.
G-1 Metzger Motor Car Co., Detroit, Mich.
G-2 Hupp Motor Car Co., Detroit, Mich.
H-1 Oakland Motor Car Co., Pontiac, Mich.
H-2 F. B. Stearns Co., Cleveland, Ohio.
J-1 Matheson Automobile Co., Wilkes-Barre, Pa.
K-1 Mitchell-Lewis Motor Car Co., Racine, Wis.
L-1 Abbott Motor Co., Detroit, Mich.

COLISEUM ANNEX—AUTOMOBILES

M-1 American Locomotive Co., 1886 Broadway, New York.
N-1 Cole Motor Car Co., Indianapolis, Ind.
O-1 Elmore Mfg. Co., Clyde, Ohio.
O-2 Baker Motor Vehicle Co., Cleveland, Ohio.
P-1 Ohio Electric Car Co., Toledo, Ohio.
Q-1 American Motors Co., Indianapolis, Ind.
Q-2 Selden Motor Vehicle Co., Rochester, N. Y.
Q-3 Bartholomew Co., Peoria, Ill.

FIRST REGIMENT ARMORY—AUTOMOBILES

A-1 Hupp Corporation, Detroit, Mich.
A-2 Waverly Co., Indianapolis, Ind.
A-3 Columbus Buggy Co., Columbus, Ohio.
A-4 Inter-State Automobile Co., Muncie, Ind.
B-1 Marquette Motor Co., Saginaw, Mich.
B-2 Moline Automobile Co., East Moline, Ill.
B-3 Rauch & Lang Carriage Co., Cleveland, Ohio.
B-4 Case Threshing Machine Co., Racine, Wis.
C-1 Garford Co., Elyria, Ohio.
C-2 Anderson Electric Car Co., Detroit, Mich.
C-3 Simplex Motor Car Co., Mishawaka, Ind.
C-4 Cartercar Co., Pontiac, Mich.
D-1 Jackson Auto Co., Jackson, Mich.
D-2 Regal Motor Car Co., Detroit, Mich.
D-3 Austin Auto Co., Grand Rapids, Mich.
D-4 DeTamble Motors Co., Anderson, Ind.
E-1 Kissel Motor Car Co., Hartford, Wis.
E-2 Staver Carriage Co., Chicago, Ill.
E-3 Krit Motor Car Co., Detroit, Mich.
E-4 James Cunningham Son & Co., Rochester, N. Y.
E-5 Great Western Auto Co., Peru, Ind.
E-6 Fiat Automobile Co., 1776 Broadway, New York.
F-1 Clarke-Carter Auto Co., Jackson, Mich.
F-2 Imperial Auto Co., Jackson, Mich.
G-1 Warren Motor Car Co., Detroit, Mich.
G-2 W. H. McIntyre Co., Auburn, Ind.
G-3 Auburn Automobile Co., Auburn, Ind.
G-4 W. A. Paterson Co., Flint, Mich
G-5 McFarlan Motor Car Co., Connersville, Ind.
G-6 Moon Motor Car Co., St. Louis, Mo.
H-1 Flanders Mfg. Co., Pontiac, Mich.

COLISEUM BASEMENT—AUTOMOBILES

1 Ideal Motor Car Co., Indianapolis, Ind.
2 Westcott Motor Car Co., Richmond, Ind.
3 Crow Motor Car Co., Elkhart, Ind.
4 Borland-Grannis Co., Chicago, Ill.
5 Broc Electric Vehicle Co., Cleveland, Ohio.
6 Streator Motor Car Co., Streator, Ill.
7 L. J. Bergdoll Motor Co., Philadelphia, Pa.
8 Zimmerman Mfg. Co., Auburn, Ind.
9 Michigan Buggy Co., Kalamazoo, Mich.
10 Lion Motor Car Co., Adrian, Mich.
11 Colby Motor Co., Mason City, Ia.
12 Lexington Motor Car Co., Connersville, Ind.
13 Ohio Motor Car Co., Cincinnati, Ohio.
14 Standard Electric Car Co., Jackson, Mich.
15 Republic Motor Car Co., Hamilton, Ohio.
16 King Motor Car Co., Detroit, Mich.
17 George W. Davis Carriage Co., Richmond, Ind.
18 Schacht Motor Car Co., Cincinnati, Ohio.

COLISEUM GALLERY—ACCESSORIES

1 Hayes Mfg. Co., Detroit, Mich.
2-3 Motz Clincher Tire & Rubber Co., Akron, Ohio.
4 C. T. Ham Mfg. Co., Rochester, N. Y.
5-5a Kinsey Mfg. Co., Toledo, Ohio.
5b Standard Roller Bearing Co., Philadelphia, Pa.
6 Atwater-Kent Mfg. Works, Philadelphia, Pa.
7 Imperial Brass Mfg. Co., Chicago, Ill.
8-9 Michelin Tire Co., Milltown, N. J.
10 Driggs-Seabury Ordnance Corp., Sharon, Pa.
11 Warner Gear Co., Muncie, Ind.
12-13 Pennsylvania Rubber Co., Jeannette, Pa.
14 Remy Electric Co., Anderson, Ind.
15 Swinehart Tire & Rubber Co., Akron, Ohio.
16 Connecticut Telephone & Elec. Co., Meriden, Conn.
17 Wheeler & Schebler, Indianapolis, Ind.
18-19 Diamond Rubber Co., Akron, Ohio.
20 N. Y. & N. J. Lubricant Co., 165 Broadway, New York.
21 Jones Speedometer Co., Seventy-sixth and Broadway, New York.
22 Weed Chain Tire Grip Co., 28 Moore street, New York.
23 Whitney Mfg. Co., Hartford, Conn.
24 Briscoe Mfg. Co., Detroit, Mich.
25 R. E. Hardy Co., Chicago, Ill.
26-27 Ajax-Grieb Rubber Co., Fifty-seventh and Broadway, New York.
28 Standard Welding Co., Cleveland, Ohio.
29 American Ball Bearing Co., Cleveland, Ohio.
30-31 Republic Rubber Co., Youngstown, Ohio.
32 Timken-Detroit Axle Co., Detroit, Mich.
33 Timken Roller Bearing Co., Canton, Ohio.
34-35 Consolidated Rubber Tire Co., 20 Vesey street, New York.
36 McCord Mfg. Co., Detroit, Mich.
37 A. R. Mosler & Co., 103 West Twenty-ninth street, New York.
38-39 Fisk Rubber Co., Chicopee Falls, Mass.
40 National Carbon Co., Cleveland, Ohio.
41 Badger Brass Mfg. Co., Kenosha, Wis.
42 Veeder Mfg. Co., Hartford, Conn.
43 Hartford Rubber Works Co., Hartford, Conn.
44 Continental Caoutchouc Co., 1790 Broadway, New York.
45 G. & J. Tire Co., 1790 Broadway, N. Y.
Morgan & Wright, 1790 Broadway, New York.
46 Gray & Davis, Amesbury, Mass.
47-48 B. F. Goodrich Co., Akron, Ohio.
49 C. F. Splitdorf, 265 Walton avenue, New York.
50 National Tube Co., Pittsburgh, Pa.

51-52 Goodyear Tire & Rubber Co., Akron, Ohio.
53 Herz & Co., 187 Elm street, New York.
54 Diamond Chain & Mfg. Co., Indianapolis, Ind.
55 Wm. Cramp & Sons Ship & Engine Bldg. Co., Philadelphia, Pa.
56 Vesta Accumulator Co., Chicago, Ill.
57 J. H. Williams Co., Brooklyn, N. Y.
58 A. W. Harris Oil Co., Providence, R. I.
59-60 Hartford Suspension Co., Jersey City, N. J.
61 Baldwin Chain & Mfg. Co., Worcester, Mass.
62 Continental Motor Mfg. Co., Muskegon, Mich.
63 Spicer Mfg. Co., Plainfield, N. J.
64 Pittsfield Spark Coil Co., Dalton, Mass.
65 Brown-Lipe Gear Co., Syracuse, N. Y.
66 Weston-Mott Co., Flint, Mich.
67-68 Firestone Tire & Rubber Co., Akron, Ohio.
69a Royal Equipment Co., Bridgeport, Conn.
69b Electric Storage Battery Co., Philadelphia, Pa.
70 Oliver Mfg. Co., Chicago, Ill.
71-72 S. F. Bowser & Co., Fort Wayne, Ind.
73 Edmunds & Jones Mfg. Co., Detroit, Mich.
74 Kokomo Electric Co., Kokomo, Ind.
75 Byrne, Kingston & Co., Kokomo, Ind.
76a U. S. Light & Heating Co., 30 Church street, New York City.
76 Stromberg Motor Devices Co., Chicago, Ill.

COLISEUM ANNEX, SECOND FLOOR—ACCESSORIES

77 Isaac G. Johnson & Co., Spuyten Duyvil, New York City.
78 Dean Electric Co., Elyria, Ohio.
79 Gabriel Horn Mfg. Co., Cleveland, Ohio.
80 A. O. Smith Co., Milwaukee, Wis.
81 Voorhees Rubber Co., Jersey City, N. J.
82 Auto Parts Mfg. Co., Muncie, Ind.
83 Eisemann Magneto Co., New York City.
84 W. H. Leland & Co., Worcester, Mass.
85 Muncie Gear Works, Muncie, Ind.
86 Leather Tire Goods Co., Niagara Falls, N. Y.
87 American Circular Loom Co., Boston, Mass.
88 Covert Motor Vehicle Co., Lockport, N. Y.
89 Link-Belt Co., Indianapolis, Ind.
90 Gemmer Mfg. Co., Detroit, Mich.
91 Havoline Oil Co., New York City.
92 Champion Ignition Co., Flint, Mich.
93 Detroit Electric Appliance Co., Detroit, Mich.
94 Auburn Auto Pump Co., Boston, Mass.
95 Heinze Electric Co., Lowell, Mass.
96 Booth Demountable Rim Co., Cleveland, Ohio.
97 Lovell-McConnell Mfg. Co., Newark, N. J.
98 Apple Electric Co., Dayton, O.
99 Bosch Magneto Co., New York City.
100 Sparks-Withington Co., Jackson, Mich.
101 Lee Tire & Rubber Co., Conshohocken, Pa.
102 Warner Mfg. Co., Toledo, Ohio.
103 Turner Brass Works, Sycamore, Ill.
104 National Coil Co., Lansing, Mich.
105 Ross Gear & Took Co., Lafayette, Ind.
106 Edison Storage Battery Co., West Orange, N. J.
107 Federal Rubber Co., Cudahy, Wis.
108 Stewart & Clark Mfg. Co., Chicago, Ill.
109 Empire Tire Co., Trenton, N. J.
110 Buda Co., Harvey, Ill.
111 Stutz Auto Parts Co., Indianapolis, Ind.
112 United Rim Co., Akron, Ohio.
113 Briggs & Stratton Co., Milwaukee, Wis.
114 George A. Haws, New York City.
115 General Electric Co., Schenectady, N. Y.
116 Jacobson & Brandlow, Pittsfield, Mass.
117 Dorian Remountable Rim Co., New York City.
118 Waukesha Motor Co., Waukesha, Wis.
119 International Acheson Graphite Co., Niagara Falls, N. Y.
120 Esterline Co., Lafayette, Ind.
121 Falls Machine Co., Sheboygan Falls, Wis.
122 Simms Magneto, New York City.
123 Western Motor Co., Marion, Ind.
124 Warner Instrument Co., Beloit, Wis.
125 Valentine & Co., New York City.
126 Batavia Rubber Co., Batavia, N. Y.
127 Gray-Hawley Mfg. Co., Detroit, Mich.
128 Avery Portable Lighting Co., Milwaukee, Wis.
129 J. H. Sager Co., Rochester, N. Y.
130 Jos. Dixon Crucible Co., Jersey City, N. J.
131 Globe Machine & Stamping Co., Cleveland, Ohio.
132 Adam Cook's Sons, New York City.
133 Hoffecker Co., Boston, Mass.
134 C. Cowles & Co., New Haven, Conn.
135 Columbia Lubricants Co., New York City.
136 C. A. Shaler Co., Waupun, Wis.
137 Pantasote Co., New York City.
138 Sprague Umbrella Co., Norwalk, Conn.
139 Continental Rubber Works, Erie, Pa.
140 Start-Lite Co., Chicago, Ill.
141 Universal Tire Protector Co., Angola, Ind.
142 Auto Supply Mfg. Co., Brooklyn, N. Y.
143 Double Fabric Tire Co., Auburn, Ind.
144 Hess Spring & Axle Co., Carthage, Ohio.
145 Doehler Die Casting, Brooklyn, N. Y.
146 G. Piel Co., Long Island City, N. Y.
147 Universal Wind Shield Co., Chicago, Ill.
148 Wolverine Lubricating Co., New York City.
149 Allen Auto Specialty Co., New York City.
150 Willard Storage Battery Co., Cleveland, Ohio.
151 Kellogg Mfg. Co., Rochester, N. Y.
152 Western Tool & Forge Co., Brackenridge, Pa.
153 Dover Stamping & Mfg. Co., Cambridge, Mass.
154 Stein Double Cushion Tire Co., Akron, Ohio.

FIRST REGIMENT ARMORY GALLERY—ACCESSORIES

1 The Horseless Age, 250 West Fifty-fourth street, New York.
2 Atlas Chain Co., Brooklyn, N. Y.
3 C. O. Tingley & Co., Rahway, N. J.
4 Barco Brass & Joint Co., Chicago, Ill.
5 Detroit Lubricator Co., Detroit, Mich.
6 Perfection Spring Co., Cleveland, Ohio.
7 U. S. Ball Bearing Mfg. Co., Oak Park, Ill.
8 The Lefever Arms Co., Syracuse, N. Y.
9 The Eagle Co., Newark, N. J.
10 The Mayo Mfg. Co., Chicago, Ill.
11 C. M. B. Wrench Co., Syracuse, N. Y.
12 Motor Vehicle Publishing Co., New York City.
13 Rhineland Machine Works Co., New York City.
14 Automatic Motor & Engineering Co., Chicago, Ill.
15 International Metal Polish Co., Indianapolis, Ind.
16 National Motor Supply Co., Cleveland, Ohio.
17 Wisconsin Motor Mfg. Co., Milwaukee, Wis.
18 S. Hoffnung & Co., New York City.
19 Findeisen & Kropf Mfg. Co., Chicago, Ill.
20 The Brown Co., Syracuse, N. Y.
21a Selbach Rubber Co., Boston, Mass.
21b Martel Blow-Out Protector Co., Chicago, Ill.
22 Sheldon Axle Co., Wilkes-Barre, Pa.
23 Peck Wheel Co., Chicago, Ill.
24 S. Breakstone, Chicago, Ill.
25 K-W Ignition Co., Cleveland, Ohio.
26 Perfect Window Regulator Co., New York City.
27 E. Edelmann & Co., Chicago, Ill.
28 Standard Varnish Works, Chicago, Ill.
29 Keystone Lubricating Co., Chicago, Ill.
30 *Motor*, New York City.
31 Frank Mossberg Co., Attleboro, Mass.
32 Norton Grinding Co., Worcester, Mass.
33 Morrison-Ricker Mfg. Co., Grinnell, Ia.
34 Chilton Co., Philadelphia, Pa.
35 The Class Journal Co., New York City (for *Motor Age*).
36 Longdin & Brugger Co., Fond du Lac, Wis.
37 The Troy Carriage Sun Shade Co., Troy, Ohio.
38 The Model Gas Engine Co., Peru, Ind.
39 Shawmut Tire Co., Boston, Mass.
40 Class Journal Co., New York City (for AUTOMOBILE).

Commercial Week at Chicago

The commercial section of the Chicago show has also undergone some changes and additions which are as follows: White Company, main floor Coliseum, space A-3; Avery Company, C-2; Morgan Motor Truck Company, M-1; Clark Delivery Car Company, M-2; Harder Fireproof Storage and Van Company, N-1. Coliseum Annex: Atterbury Motor Car Company, P-2. First Regiment Armory, main floor: Wyckoff, Church and Partridge, Inc., A-1 and A-3; Four-Wheel Drive Auto Company, B-1; Sanford-Herbert Company, B-2; Chicago Commercial Car Company, B3; A. O. Smith Company, B-6; Motor Wagon Company, C-3; Buick Motor Company, C-4; Harwood-Barley Manufacturing Company, D-3; Mercury Manufacturing Company, D-4; H. E. Wilcox Motor Car Company, D-5; Speedwell Motor Car Company, E-1; Velie Motor Vehicle Company, E-2; Poss Motor Company, E-3; Commerce Motor Car Company, F-2; Service Motor Car Company, G-2; Monitor Auto Works, G-3.

The revised list of exhibitors follows:

COLISEUM—MAIN FLOOR—AUTOMOBILES

A-1 Thomas B. Jeffery Co., Kenosha, Wis.
A-2 Baker Motor Vehicle Co., Cleveland, Ohio
A-3 White Co., Cleveland, Ohio.
A-4 Mack Bros. Motor Car Co., Allentown, Pa.
B-1 Rapid Motor Vehicle Co., Pontiac, Mich.
B-2 Reo Motor Car Co., Lansing, Mich.
B-3 Kelly Motor Truck Co., Springfield, Ohio.
B-4 Grabowsky Power Wagon Co., Detroit, Mich.
B-5 Pope Mfg. Co., Hartford, Conn.
C-1 Packard Motor Car Co., Detroit, Mich.
C-2 Avery Co., Peoria, Ill.
C-3 F. B. Stearns Co., Cleveland, Ohio.
C-4 Locomobile Co. of America, Bridgeport, Conn.
C-5 Cartercar Co., Pontiac, Mich.
C-6 Waverly Co., Indianapolis, Ind.
D-1 Garford Co., Elyria, Ohio.
D-2 Peerless Motor Car Co., Cleveland, Ohio.
D-3 Metzger Motor Car Co., Detroit, Mich.
D-4 Brush Runabout Co., Detroit, Mich.
D-5 Knox Automobile Co., Springfield, Mass.
D-6 Gramm Motor Car Co., Lima, Ohio.
E-1 American Locomotive Co., 1886 Broadway, New York.
E-2 Anderson Electric Car Co., Detroit, Mich.
E-3 Schmidt Bros. Co., Chicago, Ill.
F-1 Kissel Motor Car Co., Hartford, Wis.
F-2 Pierce-Arrow Motor Car Co., Buffalo, N. Y.
G Reliance Motor Truck Co., Owosso, Mich.
H General Motors Co., Detroit, Mich.
J Staver Carriage Co., Chicago, Ill.
K Lozier Motor Co., Detroit, Mich.
L W. H. McIntyre Co., Auburn, Ind.
M-1 Morgan Motor Truck Co., Worcester, Mass.
M-2 Clark Delivery Car Co., Grand Crossing, Chicago.
N-1 Harder Fireproof Storage & Van Co., Chicago.
N-2 Federal Motor Truck Co., Detroit, Mich.
N-3 Adams Bros. Co., Findlay, Ohio.

COLISEUM ANNEX—MAIN FLOOR—AUTOMOBILES

O Eclipse Truck Co., Franklin, Pa.
P-1 Alden-Sampson Mfg. Co., Detroit, Mich.
P-2 Atterbury Motor Car Co., Buffalo, N. Y.
Q-1 Durant-Dort Carriage Co., Flint, Mich.
Q-2 U. S. Motor Truck Co., Cincinnati, Ohio.
Q-3 Dayton Auto Truck Co., Dayton, Ohio.
Q-4 Dorris Motor Car Co., St. Louis, Mo.
R Mais Motor Truck Co., Indianapolis, Ind.
S General Vehicle Co., Long Island City, N. Y.

FIRST REGIMENT ARMORY—MAIN FLOOR—AUTOMOBILES

A-1 Wyckoff, Church & Partridge, Inc., New York.
A-2 Walker Vehicle Co., Chicago, Ill.

A-3 Wyckoff, Church & Partridge, Inc., New York.
A-4 Stegeman Motor Car Co., Milwaukee, Wis.
B-1 Four-Wheel Drive Auto Co., Clintonville, Wis.
B-2 Sanford-Herbert Co., Syracuse, N. Y.
B-3 Chicago Commercial Car Co., Chicago, Ill.
B-4 Lauth-Juergens Motor Car Co., Fremont, Ohio.

Cleveland Show Gets Club Sanction

CLEVELAND, OHIO, Nov. 20.—A meeting of directors of the Cleveland Automobile Show Company was held recently and a committee to manage the 1912 show was chosen consisting of the following: Frank W. Phillips, H. M. Adams, C. N. Brockway, Ray M. Colwell and Fred C. Wood.

This show committee will manage the coming season's show with the sanction and assistance of the Cleveland Automobile Club.

Fred H. Caley, secretary of the Cleveland Automobile Club, will act as assistant secretary and the offices will be in the Hollenden Hotel.

Big Exhibition Planned at Baltimore

BALTIMORE, MD., Nov. 20.—The Automobile Club of Maryland and the Baltimore Automobile Dealers' Association have decided upon February 20 to 28 for the next motor car show to be held in this city. The only thing holding back the rushing of the plans is the answer to the application of the two organizations forwarded to Major Washington Bowie, Jr., of the board of trustees of the Fifth Regiment Armory for use of the armory. Both bodies have announced that the coming show will be run on larger plans than ever before and for this reason they are beginning arrangements earlier than usual.

Garden Truck Show to Have 231 Exhibitors

Plans and preparations already made for the second annual display of motor trucks and delivery wagons to be held in Madison Square Garden, New York, during the second week of the Twelfth National Automobile Show, January 15 to 20 inclusive, indicate plainly that the commercial week will be a close second to passenger car week in magnitude and interest. Every square foot of space utilized the first week has been sold for the following week to thirty-one manufacturers of trucks and delivery wagons, and two hundred motor car accessories makers.

Business machines of all types and sizes will be displayed, ranging from package delivery cars of about 600 pounds capacity to 10-ton trucks. There will be twenty-seven makes of gasoline machines and eleven makes of electric wagons. Besides the ordinary styles of trucks and delivery wagons, there will be many machines for special purposes, such as motor fire engines, patrol wagons, ambulances, trucks with tipping bodies and trucks with power winches for hoisting purposes.

Fall Show at Indianapolis

INDIANAPOLIS, IND., Nov. 20—Members of the Indianapolis Automobile Trade Association are holding their first Fall show this week. Each member is exhibiting in his own place of business and the different salesrooms are beautifully decorated for the week. A special feature is a free 'bus service for taking visitors from one salesroom to another. There are forty-three cars in this service for the week, loaned by members of the association.

Thursday afternoon has been selected as "Ladies' Day" and during the afternoon special attention will be given to the display of electrics, coupés, limousines and other closed body cars.

Show at Canadian Capital

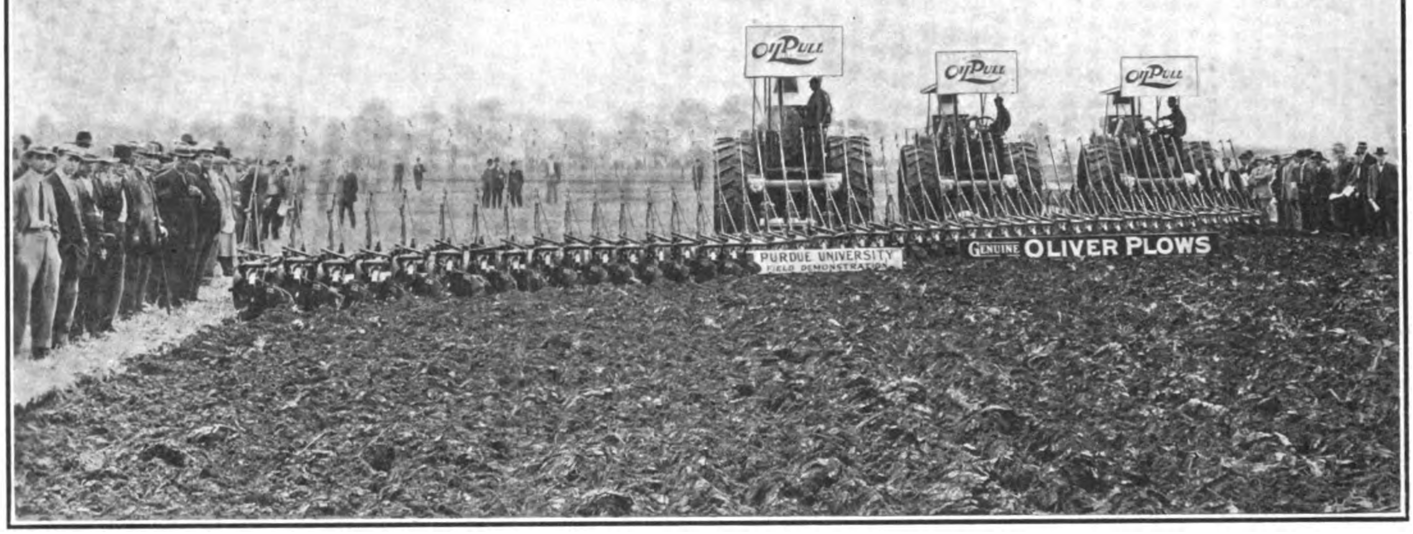
OTTAWA, CAN., Nov. 20—Ottawa's first annual automobile show will be held April 6 to 13, 1912 in Howich Hall, under the auspices of Ottawa Valley Motor Car Association. Howich Hall is the largest building in the city comprises about 40,000 square feet, half of which has already been sold. The Governor-General Foot Guard's Band has been engaged to furnish music during the show. The show committee has made plans to have the decorative feature of the show the best ever seen in Canada. Louis Blumenstein has been engaged as manager, with offices at 49 Metcalf street, Ottawa, Canada.

Akron Is Actually Building Roads

AKRON, OHIO, Nov. 20—The result of the past two years' good road building activity in this vicinity shows that within a short time there will be three brick roads connecting Akron and Cleveland, a distance of 35 miles, and Akron and Canton on the south, making an improved straightaway road more than 50 miles in length through beautiful touring territory. In Cuyahoga county, of which Cleveland is the county seat, there are already brick roads in all directions from the city to the county line, including two in the general direction of Akron.

Pavement from Akron north to connect with one of the Cleveland roads is already nearly done, and plans are for another big road building year in 1912. Summit county has completed 31 1-2 miles of country road paving this year. Twenty-five miles more are covered by the petitions filed with the county commissioners for next year.

NEWS of the WEEK CONDENSED



Plowing demonstration recently given at Purdue University with three oil-pull tractors and fifty plows

SOUTH BEND, IND.—Three Rumely oil-pull tractors and fifty Oliver plows broke the world's record for plowing recently in a demonstration at Purdue University, Lafayette, Ind. The demonstration was arranged by Joseph D. Oliver, president of the Oliver Chilled Plow Works and also a trustee of Purdue, and President Stone of the university. Sections of the mammoth Oliver plow were hauled into place, and W. L. Paul, designer of the big fifty-bottom sectional plow, dropped the plows across the end of the field in an exact line. They turned the stubble field at the rate of 1 acre every 4 minutes and 15 seconds. The strip plowed was 58 feet 4 inches wide. The engines were operated on a low grade of kerosene distillate costing 4 cents a gallon. The three engines consumed 22 gallons an hour, reducing the fuel cost to less than 6½ cents an acre.

BEAVER CITY, NEB.—A new garage is being erected here by Birsell & Son.

ST. PAUL, NEB.—Charles Guggenman has taken the agency for the Hudson in this territory.

OCALA, FLA.—Work has begun on the erection of a $10,000 garage for R. L. Anderson.

BATTLE CREEK, NEB.—Fuerst and Huerman will erect a new garage here in the near future.

WYMORE, NEB.—The Lyons Automobile Company has bought out the automobile business of E. W. Severance & Son.

ABERDEEN, WASH.—J. B. Knight is handling the Mitchell car in the Gray's Harbor country, with headquarters in this city.

CORNING, N. Y.—The Corning Automobile Company has leased the Hillman Garage at Wall street and Tioga avenue. Max Wolcott is manager of the company.

BOSTON, MASS.—F. L. Sanford has joined the sales force of the Henley-Kimball Company, and is in charge of the wholesale department for outside territory on Hudson cars.

NEW YORK CITY—The Hexter Motor Truck Company of New York, metropolitan distributor for the Gramm, is erecting a service maintenance building at 155-159 Perry street.

BUFFALO, N. Y.—William J. Clements, formerly manager of the Detroit branch of the Krit Motor Car Company, has been promoted to the position of manager of the company's branch in this city.

CHICOPEE FALLS, MASS.—A. M. Welch, formerly with the Studebaker Company, and for the past year manager of the Commercial Car Department of the Franklin works at Syracuse, N. Y., has taken up territorial work with the Stevens-Duryea Company, of this city.

PITTSBURGH, PA.—H. L. Mason, Jr., was recently elected president of the Automobile Club of Pittsburgh, to succeed Edward Kneeland, who resigned on account of the pressure of other business. Mr. Mason will remain in office until the annual election on February 1.

NEW YORK CITY—Fred W. Wright, of No. 250 West Fifty-fourth street, who recently took the local agency for the Lion car, has placed agencies with the Watson Automobile Company, of Fishkill, N. Y.: John S. Carpenter, of Goshen, N. Y., and the McFarlan-Brooklyn Company, of Brooklyn, N. Y.

NEW YORK CITY—The city fire department is soon to be augmented by a monster self-propelling pumping engine which will make up to 40 miles an hour and throw 700 gallons of water a minute. The engine is about 18 feet long, with a wheel-base of 146 inches. It weighs, complete, nearly 7 tons and runs on 42-inch wheels with solid tires.

YORK, NEB.—The York Automobile Club is taking an active part in pushing the Canada-to-Gulf route, known here as the Meridian road. It is proposed that the road run through York, and the members of the club have all been assessed $5 to support the project. It was voted to use the club money to purchase markers for the road through the county.

PORTLAND, ORE.—Several new Mitchell agencies have been placed in the Northwest during the past month. Among them are: the Ellensburg Auto Company, of Ellensburg, Wash., the Milton Garage of Milton, Ore., and the Simonton Motor Company, of Salem, Ore. The Mitchell will be represented in this city by the firm of Dulmage & Smith, who have recently erected a large garage and salesroom.

INDIANAPOLIS, IND.—The Ocean-to-Ocean booklet, containing 108 illustrations and telling in detail the story of the transcontinental tour of 12 Premier cars, has found a place in the public schools of this city. John G. Monihan, secretary of the 40 tourists who crossed the continent last summer, has received thousands of requests for these booklets, many of which have come from teachers and librarians.

WASHINGTON, D. C.—E. T. Howard has joined the sales force of the Marion Motor Car Company.

CHARLESTON, W. VA.—A company has been organized to manufacture automobile trucks in this city.

SHEBOYGAN, WIS.—Dr. H. A. Wagner and M. G. Dohme are building a garage at 1519 North Sixth street.

LOS ANGELES, CAL.—The Michigan car has been introduced into Southern California by C. L. Perrin, who has opened an agency.

DALLAS, TEX.—W. G. Langley, the local agent for the Franklin, recently opened a new garage at 1713 Commerce street in this city.

TORONTO, ONT.—The Gem City Garage Company is enlarging its present building by the addition of a well-equipped machine and repair shop.

UTICA, N. Y.—The Oneida Garage Company, George A. McCracken general manager, will erect a two-story concrete garage at 215 Park avenue.

WILMINGTON, DEL.—W. D. Haddock & Co. have secured the contract for the construction of a garage to be built for the Wilmington Steamboat Company.

JANESVILLE, WIS.—Edward Kemmerer has commenced work on the construction of a brick and steel garage building to contain 15,000 square feet of floor space.

MINNEAPOLIS, MINN.—L. H. Fawkes is to erect a three-story brick and reinforced concrete automobile warehouse at 1629 Hennepin avenue. It will cost $35,000.

ST. LOUIS, MO.—A. H. Collins, sales manager of the Herreshoff Motor Company, of Detroit, has closed with George E. Maguire for St. Louis and surrounding territory.

WASHINGTON, D. C.—Additional territory has been assigned to W. P. Barnhart, local representative of the Everitt car. The new field covers the states of Virginia and North Carolina.

AKRON, O.—E. I. Whorley, formerly branch manager of the Dallas, Tex., branch of the B. F. Goodrich Company, has accepted a position with the Motz Tire & Rubber Company, of this city.

SEATTLE, WASH.—J. M. Stehman, formerly with J. E. Leavitt & Company, is now connected with the Mitchell Motor Car Company of this city. He will represent the company in all the Northwest territory outside of Seattle.

NEW YORK CITY.—The Eastern and Central district branch managers and salesmen of the United States Tire Company held a meeting here recently. An all-day business session was followed by a dinner at the Hotel Astor.

SALEM, O.—T. A. Vernon has sold half interest in his garage on Ellsworth avenue to E. A. Saren, of Alliance, O. Mr. Saren has taken active management of the garage though Mr. Vernon retains his district agency for the Everitt car.

MOLINE, ILL.—John E. Miller, chief engineer of the Midland Motor Company, of this city, and designer of the Moline car, was killed recently while crossing a railroad track just outside of the Midland factory yards at East Moline, Ill.

SCRANTON, PA.—John H. Felming, proprietor of the city hall garage, 330-336 Dix court, has acquired the distributing rights in Luzerne county and northeastern Pennsylvania for the American cars built by the American Motors Company, of Indianapolis, Ind.

PROVIDENCE, R. I.—According to the table of automobile trucks just compiled by the American Locomotive Company, 62 per cent. of all the trucks have been purchased on repeat orders and 78 per cent. of those in the service of department stores are re-orders.

SEATTLE, WASH.—William O. McKay, a University of Washington man, and J. D. Thomas, will open a Locomobile agency in this city. The Thomas-McKay Company, Inc., will have temporary quarters at 211 Broadway north. Mr. Thomas intends to erect a large garage in the near future.

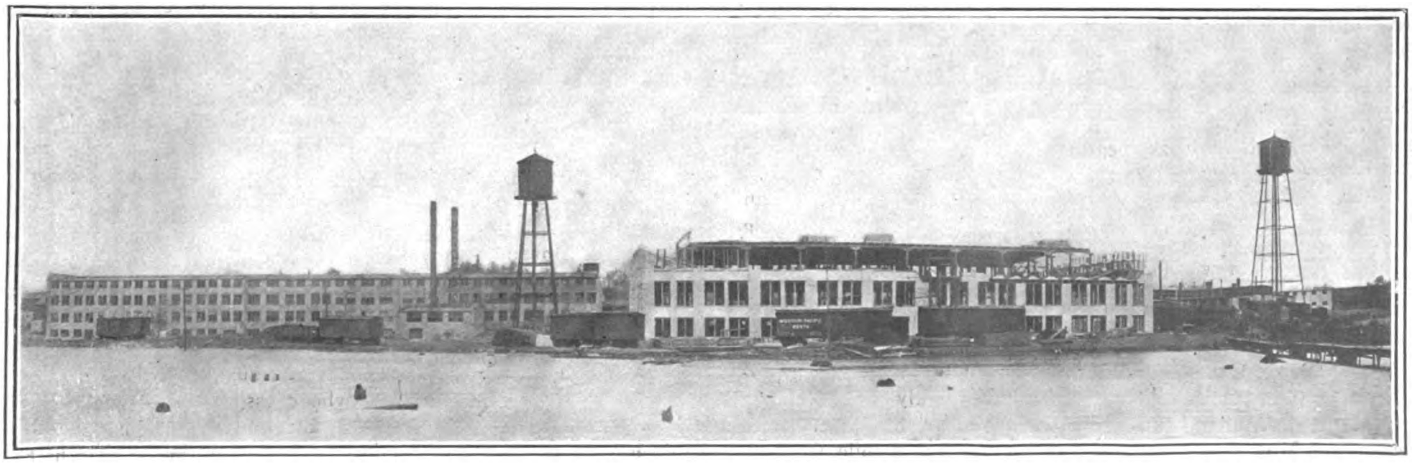
LOS ANGELES, CAL.—Joe Ollier, manager of the southern California branch of the Studebaker Bros. corporation, has announced the formal moving of the local branch to the new building at 1620-22-24 East Seventh street. The R. C. H. Sales Agency will occupy the quarters recently vacated by the Studebaker Company.

LOS ANGELES, CAL.—Tiring of the monotony of railroad travel, A. N. King and wife, an aged couple of Anderson, Ind., purchased a Maxwell runabout and drove from Anderson to their Winter home near here, covering more than 3,000 miles. Part of the time was spent in camping on the road and the balance as guests of ranchers.

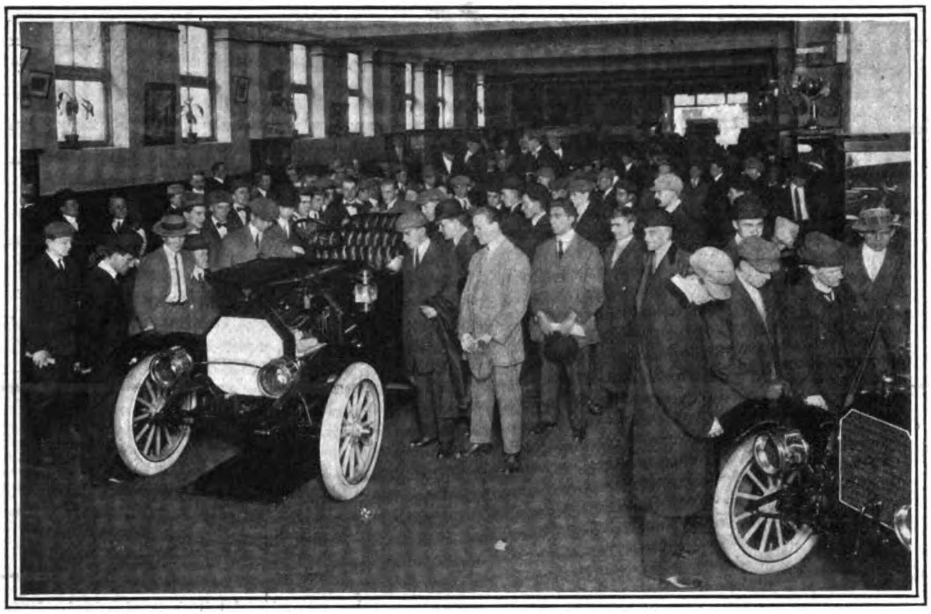
BOSTON, MASS.—The latest acquisition of Sampson automobile trucks by the New England Telephone & Telegraph Company gives that organization a total of twenty machines—17 of 3,000 pounds capacity, 2 of 1,500 pounds and 1, the first purchased, of 4 tons. The fleet operates between a central station in this city and various stations throughout the State.

HARTFORD, WIS.—The construction work on the new addition to the KisselKar plant is rapidly progressing. The new structures, which will be under cover within thirty days, consist of a three-story concrete building, 107 by 407 feet, and a one-story building, 50 by 407 feet. Additional machinery and equipment are being rapidly installed and the factory will be equipped with an electric trolley system for economically transporting all machinery and parts from one department to another.

RACINE, WIS.—Papers have been filed in the suit of the Knox Automobile Company, of Springfield, Mass., against William A. Crane, of this city, to recover on a $10,000 bond given by Mr. Crane in behalf of his son, George R. Crane, of Milwaukee, in 1904, upon acceptance of the Knox agency in a large territory contiguous to Milwaukee and Chicago. In October, 1906, the younger Crane went into voluntary bankruptcy, among the liabilities being $13,666.34 due the Knox company. He was discharged from bankruptcy in February, 1907. The complaint of the Knox company states that Crane handled $139,000 worth of cars while he represented it in Milwaukee.



The new addition to the KisselKar plant at Hartford, Wis., will be under cover in thirty days



Group of Y. M. C. A. students inspecting Maxwell cars at the New York branch

LOUISVILLE, NEB.—The garage of William Vlok has been purchased by Haney Brothers.

SAN DIEGO, CAL.—The Bowler Motor Car Company is now the local agent for the Cole car.

SHEBOYGAN, WIS.—Arthur F. Raab, 809 North Eighth street, is a new agent for the Sampson 35.

SAN DIEGO, CAL.—The Hunt Automobile Company of this city has secured the agency for the Overland car.

DAVID CITY, NEB.—The David City Auto Company's new garage has been completed recently and is now in operation.

SAN DIEGO, CAL.—The Bay City Garage of Fifth and Ash streets, has recently taken the agency for the Everitt car in this vicinity.

PORTLAND, ORE.—L. A. Harding, president of the Nob Hill Garage & Auto Company, has taken the local agency for the American.

DES MOINES, IA.—The Brown-Corley-Ellis Company this week secured the Iowa agency for the Lozier car. The company will move into new quarters within a few weeks.

SAN DIEGO, CAL.—W. A. Chamberlain, formerly with the Firestone Tire & Rubber Company, of Akron, O., is now associated with the Tibbals-Gavin Company of this city.

DES MOINES, IA.—Secretary of State W. C. Hayward is now receiving registrations for 1912 auto licenses at the rate of 150 a day. The new numbers must be assigned by January 1.

SAN DIEGO, CAL.—W. Pitt Fessenden, formerly of Los Angeles, has recently taken charge of the William R. Ruess Automobile Company in this city, and will handle the Pope-Hartford car.

PORTLAND, ORE.—C. A. Eastman has resigned as manager of the White Motor Car Company, of Portland. His place will be taken by S. G. Houston, a member of the company's force.

MILWAUKEE, WIS.—Percy C. Avery, a well known inventor and manufacturer of motor car appliances in this city, has been elected treasurer of the Milwaukee Automobile Club to succeed Clarke S. Drake.

SAN DIEGO, CAL.—The Western Motor Car Company has leased a new home and will shortly move to Front and C streets. The Bateman-Buoy Company has secured the local agency for the Flanders and E-M-F cars.

PRAIRIE DU CHIEN, WIS.—Brunton & Foss, operating the Prairie City Garage, have dissolved partnership and the business will be continued by Mr. Foss. Mr. Brunton goes to Beloit, Wis., to engage in the garage business.

DES MOINES, IA.—A branch of the Interstate Auto and Supply Company, of Sioux City, will be opened here this week. George Jamieson will be manager. H. B. Groves, the proprietor, will take charge of the Sioux City business.

SAN DIEGO, CAL.—Charles W. Stream, general sales manager of the automobile department of the International Harvester Company, will make his home here this Winter, assisting P. M. Price in the sale of International auto wagons.

SEATTLE, WASH.—C. W. Dansie, for some time past with the Olympic Motor Car Company of this city, has been promoted to the managership of the firm. The Olympic Motor Car Company, handles the Everitt, Chalmers, Herreshoff and Pope-Hartford cars.

DES MOINES, IA.—The Colby Motor Car Company of Mason City will open a branch in this city within a very short time. Quarters have been secured at 1017 Walnut street. W. H. Shadbourne, sales manager for the Colby company, will be in charge of the local branch.

COLUMBUS, O.—State Registrar of Automobiles, J. A. Shearer, has made his report for the quarter ending November 15, as follows: Number of owners registering cars, 2,907; number of chauffeurs securing licenses, 589; manufacturers and dealers registering, 51; duplicate tags furnished, 153. The total receipts for the quarter was $16,-976.40. Up to November 15 the department had issued 45,711 sets of number plates.

INDIANAPOLIS, IND.—After trying one line less than one month, the Rapid Motor Transit Company of this city is seriously considering the question of installing additional motor-bus lines. The present line is on North Meridian street. The new lines contemplated are in Broadway, from Massachusetts avenue to Fall Creek, and a cross town line about 7 miles long, running across the north side of the city from Brightwood to Riverside Park.

INDIANAPOLIS, IND.—Will H. Brown, president of the Mais Motor Truck Company, has been made chairman of a committee of the Indianapolis Trade Association to arrange a trade extension trip through southern States for the month of February. A special train, carrying Indianapolis and Indiana manufacturers, jobbers and wholesalers, will visit Louisville, Nashville, Atlanta, Macon, Birmingham, Jacksonville, Albany, Savannah, Montgomery, Mobile, Meridian, Jackson and Memphis.

COLUMBUS, O.—Asserting that Frank Meville, of Bellefontaine, O., doing business as the Standard Automobile Company, had filed in the probate court of Logan county, O., a petition of assignment and had previously given mortgages to prefer two creditors, the King Top Manufacturing Company, of Dayton, the E. L. Essly Machinery Company, of Chicago, and the Hamilton Bros. Company, of Bellefontaine, have filed a petition in the United States court under the bankruptcy act asking that an investigation and a fair distribution of the assets be made.

NEW YORK CITY—One hundred and twenty-five members of the West Side Y. M. C. A. automobile class visited the Maxwell and Columbia salesrooms in Sixty-first street near Broadway recently to inspect the 1912 models, the Maxwell cars that won the Glidden Tour and the latest Columbia cars equipped with the Knight sliding-sleeve motor. After inspecting these, the party entered automobiles at the door and rode to the factories of the Maxwell-Briscoe Motor Company at Tarrytown and Kingsland Point, where they saw the process of building automobiles from the entry of raw material to the shipping of the finished product.

COLUMBUS, O.—D. W. Short, 14 East Swan street, has taken the central Ohio agency for the 1912 Metz.

COLUMBUS, O.—J. B. Hoover, 621 North Fourth street, has taken the 1912 agency for the Nyborg 35. His territory covers central Ohio.

BOSTON, MASS.—The Haynes car is now represented in Boston by the W. L. Russell Company. This company also has the Regal agency.

FREMONT, O.—E. E. Pease has been placed in charge of a new concern which will open a factory for the manufacture of automobile tops. It will be located on North Arch street.

INDIANAPOLIS, IND.—The Merchants Auto Company, recently organized here, has located in North Delaware street. The company has taken the Indiana agency for the Woods electric.

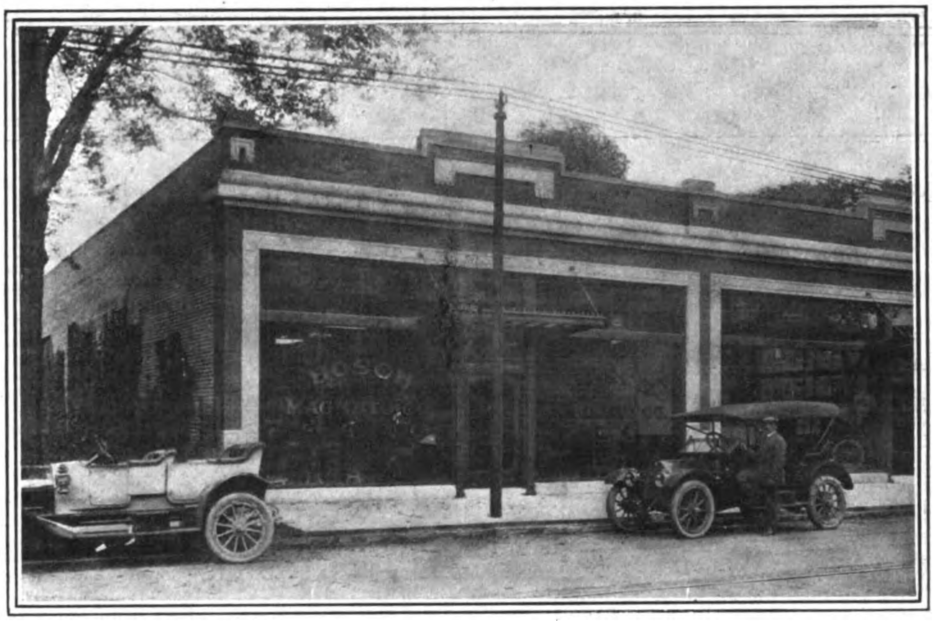
INDIANAPOLIS, IND.—At a recent meeting the local board of public safety decided to ask for an appropriation of $4,500, which will be used to buy a new emergency seven-passenger touring car for the police department.

SANDUSKY, O.—The capital stock of the Sandusky Auto Parts & Motor Truck Company of this city, has been increased from $15,000 to $500,000. A. F. Knotts is president and R. D. Mitchell secretary of the corporation.

COLUMBUS, O.—The United States Carriage Company, of Columbus O., which makes a specialty of automobile hearses and funeral cars, has evolved a motor hearse which is entirely different from any thing now in use.

COLUMBUS, O.—A shipment of 10,000 sets of number plates for 1912, for the Ohio State Automobile Department, has been made by the Scioto Sign Company, of Kenton, O., which firm supplies the tags for the coming year. The 1912 tags will be on a white background with letters in green. The usual style of the number in large figures and the name "Ohio" and the year "1912" at the end of the tag will be followed.

DETROIT, MICH.—The local branch of the Bosch Magneto Company, of New York, is now located in its new quarters at 1250-1252 Woodward avenue close to the corner of Henry street. The building has recently been completed, and is so arranged that the business of the company can be easily handled. Not only has the space been greatly increased over that occupied in the old building, but the staff of mechanics and ignition experts is now doubled, thus the branch is in a position to make repairs or installations on cars at a moment's notice. The offices are located at the front of the building, and back of the salesrooms is a large laboratory and repair shop. Still farther to the rear is a spacious garage.



New quarters of the Detroit branch of the Bosch Magneto Company

Automobile Incorporations

AUTOMOBILES AND PARTS

ASHEBORO, N. C.—Asheboro Motor Car Co.; capital, $5,000; to sell motor cars. Incorporators: M. L. Davis, C. Rush, I. N. Cox.

NEW YORK CITY—Trautman Air Rubber Tube Co.; capital, $100,000; to manufacture automobile tires. Incorporators: Ira Trautman, August V. Denis, Wm. G. Newhall.

NORFOLK, VA.—Virginia Automobile Garage & Repair Corporation; capital, $10,000; to conduct a garage business. Incorporators: H. L. Page, A. M. Bopp, P. A. Page.

PHILADELPHIA, PA.—Motor Spring Co.; capital, $1,000,000; to manufacture and deal in self-starting devices. Incorporators: Leonard E. Wales, L. E. Replogle, Lew W. Cooper.

RICHMOND, VA.—Broad Street Garage; capital, $5,000; to conduct a garage. Incorporators: A. Zachary, O. B. White, C. Stokes.

ST. LOUIS, MO.—Curtis Jack & Truck Co.; capital, $75,000; to make a combination jack and hand truck for automobiles. Incorporators: J. R. Curtis, H. C. Flunker, A. W. Smith, Otto Stifel, George E. Booth.

ST. LOUIS, MO.—Schelph-Budke Tire & Rubber Co.; capital, $10,000; to manufacture automobile tires. Incorporators: Geo. H. Schelph, C. Milton Schelph, Conrad Badke, Jr.

OF INTEREST to the INDUSTRY

New storage battery department of the Apple Electric Company at Dayton, O.

DAYTON, OHIO—The Apple Electric Company, of this city, has added a new battery department to its plant. The new department is fully equipped for the work of turning out storage batteries in large quantities. The company makes a specialty of electric lighting systems for automobiles, motor boats and country homes.

NASHVILLE, TENN.—The Tennessee Auto Company is erecting a $4,500 building.

ALEXANDRIA, VA.—The B. F. Board Motor Truck Company is planning to erect an additional building.

BUTLER, PA.—New machinery is being purchased to add to the equipment of the Butler Vulcanizing Company.

RICHMOND, VA.—Ground has been broken for an automobile factory which the Kline Motor Car Company is to erect in this city at a cost of $300,000.

BUFFALO, N. Y.—The Niagara Gasoline Motor Company of this city is building a one-story brick addition to its plant at Breckenbridge and Barton streets.

WILKES-BARRE, PA.—G. S. Delaney has entered the employ of the Matheson Automobile Company as factory manager and has assumed his duties at the local plant.

LANSING, MICH.—The Hildreth Manufacturing Company has increased its capital stock from $75,000 to $112,500. The company makes gasoline motors and pumps.

ELMIRA, N. Y.—The Morrow Manufacturing Company, of this city, manufacturer of automobile parts, is adding a large amount of new machinery to the equipment of its plant.

LOUISVILLE, KY.—The Continental Car and Equipment Company, of this city, has developed a 3 1-2-ton truck which it will manufacture either here or in New York. McKinley Boyle is president of the company.

MONROE, WIS.—Fred Herrmann, formerly assistant foreman of the testing laboratories of the Thomas B. Jeffery Company, in this city, is now associated with Richard Patterson in the management of the Monroe Automobile Company.

PONTIAC, MICH.—Don McCord, formerly sales manager of the Marion plant, has been appointed general manager of the Flanders Electric factory in this city. Mr. McCord has been sales manager of this firm for several weeks.

DETROIT, MICH.—The Timken Roller Bearing Company and the Timken-Detroit Axle Company have established an advertising department. Edwin A. Walton, formerly assistant advertising manager of the Burroughs Adding Machine Company, is manager.

DETROIT, MICH.—Architects Albert Kahn and Ernest Wilby have awarded the A. J. Smith Construction Company the general contract for the new testing shed of the Hudson Motor Car Company at 2901 Jefferson avenue. The shed is to be a two-story brick building, 50 by 500 feet.

NASHVILLE, TENN.—The Marathon Motor Works of this city has increased its capital stock to $1,000,000 and has purchased the plant of the Carbon & Oil Company adjoining its present plant. New equipment, to cost about $225,000, will be installed and the product of the works will be increased to 3,500 cars a year.

DETROIT, MICH.—Through the merging of the sales organizations of the Rapid and the Reliance divisions of the General Motors Truck Company, L. J. Fasquelle is now general sales manager of the company. T. P. Myers is in charge of the company's service department.

BUDAPEST, HUNGARY—American automobile manufacturers are neglecting a fertile European field in this country. The American automobile is practically unknown here in spite of the general prosperity of the 20,000,000 inhabitants and most of the machines in use are of French make.

NEW YORK CITY—American automobile manufacturers appear to be finding a better market in other parts of the world than in Europe, for during the first eight months of this year, the exports of American cars to South America exceeded in value those to France, Germany or Italy, and the exports to British Oceania were not far behind those to the United Kingdom.

NEW YORK CITY—Henry C. McComb, chief engineer for the E. R. Thomas Motor Company before its reorganization, recently resigned as assistant general manager of the Louis J. Bergdoll Motor Company. He has joined the forces of Wyckoff, Church & Partridge, Inc., of Fifty-sixth street and Broadway, this city, as manager of the commercial engineering department.

LOS ANGELES, CAL.—The Moro is the name given to the new car produced by J. B. Morrow, of Morrow, Loomis & Co., a local automobile firm, and James R. Fouche. A large building has been leased and it is expected that by January 1 all necessary equipment will be in place and the manufacture of a number of cars begun.

LOUISVILLE, KY.—The Kentucky Wagon Manufacturing Company has succeeded to the business of the Electric Vehicle Company, by the purchase of the designs, drawings, patterns and equipment of the latter company, and will build all sizes of electric commercial vehicles. H. Hewitt, who was in charge of the Electric Vehicle Company, has been made general manager of this department.

NEW YORK CITY.—Mr. W. Walter, who has been manufacturing commercial cars at 49-51 West Sixty-sixth street in this city, has incorporated the Walter Truck Company to take over the business. The new company will manufacture the same models on a larger scale. A factory and garage will be erected in the neighborhood of Broome street. Mr. Walter is president of the company and will give his attention to the making of trucks. Mr. Fletcher, the secretary and treasurer, will look after the selling end of the business.

PATENTS GONE TO ISSUE

CLUTCH.—Friction device of the expanding band type.

3. This clutch (Fig. 1) consists of a driving and a driven member, one of the members being in form of a shaft and the other in that of a pulley. To the shaft a clutch disc is fixed, and an expansion ring is adapted to engage the inner surface of the pulley. An expansion ring is provided which may be made to engage the inner surface of the pulley, while an expansion lever pivoted to the disc engages one end of the ring. Means are provided to actuate this lever, and a movable device carried by the disc and acted on by the other end of the ring may be operated to apply positive outward pressure to the ring.

No. 1,008,945—to John C. Brewin, Philadelphia, Pa. Granted November 14, 1911; filed December 14, 1910.

AUTOMOBILE SLEIGH—A vehicle for Winter travel in cold countries.

4. This patent relates to a construction (Fig. 2) of a vehicle having a front axle structure carrying vehicle-supporting members, and a vehicle body supporting bearing frames at its rear end. Outer shaft sections are journaled in the bearing frames, and to these sections wheels are fixed. A vertical arch frame is mounted on the bearing frames and has journal boxes vertically reciprocable in opposite sides of it.

In the journal boxes an intermediate shaft section is journaled, and coupling mechanisms intervene between the ends of the intermediate shaft and the adjacent ends of the outer shaft sections, whereby the latter may be connected or disconnected. On the intermediate shaft section a spur propulsion wheel is mounted, which drives the mechanism of the vehicle.

No. 1,008,409—to Alexander Finkelstein, Chicago, Ill. Granted November 14, 1911; filed March 27, 1911.

STEERING AND DRIVING MECHANISM.—A combination of these two functions in one device.

1. This patent refers to a combination (Fig. 3) with a cross member of brackets depending at each end of that cross member, oil casings supported by the brackets between themselves and the cross member, and shafts which are journaled in the casings mentioned. To the shafts wheels are secured, and they also carry, within the casings, bevel gears, which in turn mesh with bevel gears. On the cross member oil casings are mounted, in which a driving gear is located, which serves to drive the second-mentioned bevel gears. Means are provided to operate the driving mechanism. Lugs on the first-mentioned rotatable oil casings extend in opposite directions therefrom, and parallel steering rods connect the lugs so that the first-mentioned oil casings may be rotated to steer the wheels mentioned.

No. 1,008,376—to Samuel E. Siders, Delphos, Kan., and George A. Siders, Novinger, Mo. Granted November 14, 1911; filed October 26, 1909.

MACHINE FOR MAKING RUBBER SHEETS.—Apparatus designed for converting latex into crude rubber.

This machine contains a rotatable metallic drum with enclosed ends and means for uniformly applying heat to the drum periphery, from the interior thereof. A vat containing latex delivers it intermittently to the drum periphery, and means are provided to remove the vat from the drum after every application of latex, and to elevate it again to apply another coat of the material after the preceding coat has been dried by the hot drum.

No. 1,008,607—to Frank E. Mellinger and Henry H. Markley, Lumija, Mexico. Granted November 14, 1911; filed January 19, 1911.

SPARK PLUG.—In which a special design of support for the insulation is used.

3. The plug (Fig. 4) has an insulation mass with an enlarged portion surrounded by gaskets enclosed by a soft metal band. This band has an enlarged middle portion lying between the gaskets to stiffen the band and space the gaskets.

No. 1,008,485—to Charles A. Mezger, New York, N. Y. Granted November 14, 1911; filed November 23, 1908.

BRAKE CONNECTIONS.—Means for applying the brakes to a vehicle wheel.

2. The device is of the friction class and combines an axle with a friction member on it and rotates with it, and an opposed friction member which has an annular groove. A frictional surface is composed of an annular series of radial independent sections, which are interposed between the friction members and loosely confined when the brakes are released.

No. 1,008,792—to John H. Davis, Brooklyn, N. Y., assignor to Momentum Automatic Brake Company, New York, N. Y. Granted Nov. 14, 1911; filed July 24, 1909.

FRICTION DEVICE—Shock absorber in which two inversely positioned series of wedges take up thrust transmitted to device.

2. The patent refers to a device composed of a wall against which a series of wedge members have their bases resting, and on which they are laterally movable, the wedges being partially intermeshed with a series of inverse wedge members which are endwise movable. The base end of the latter wedges project beyond the apices of the first-mentioned series, and a cam having a waved surface acting upon the projecting bases of the second-mentioned series of wedges moves in a path substantially parallel to the wall.

No. 1,008,635—to Phelps M. Freer, Barberton, Ohio. Granted November 24, 1911; filed February 5, 1910.

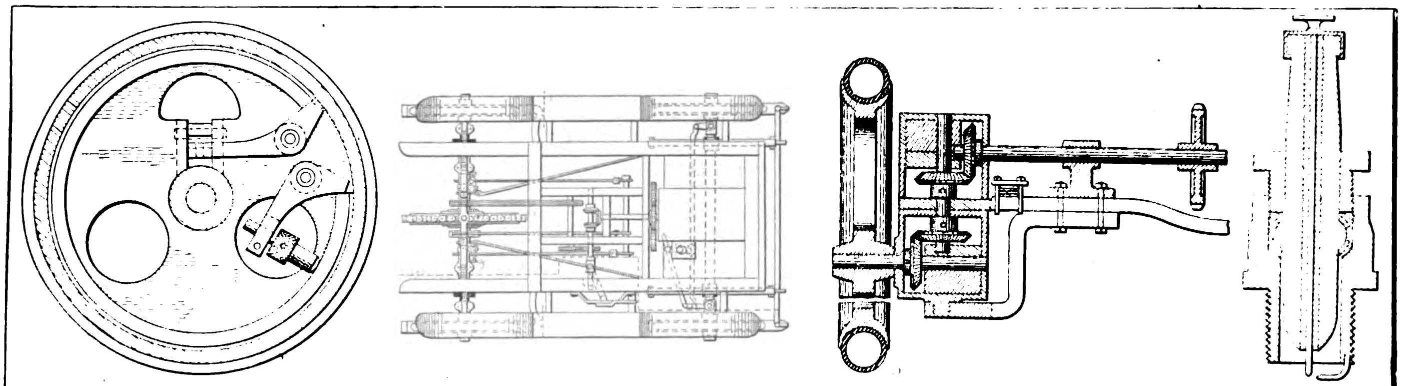

Fig. 1—Brewin friction clutch. Fig. 2—Finkelstein sleigh. Fig. 3—Siders steering and driving mechanism. Fig. 4—Mezger spark plug

Newest Ideas Among the Accessories

Automatic Lock Switch

THE Automatic Lock Switch, which is illustrated in Fig. 1, is made the idea of preventing the starting of an automobile by an outsider who has no business to do this. It consists of a Yale lock, which is placed over the face of the coil box on the dashboard in place of the ordinary switch. Turning the key to the right or left, as the case may be, brings the switchbar into contact with the battery or magneto points, depending on whether the former or latter kind of circuit is used. It is impossible to withdraw the key, except when the current is broken or on neutral; nor can a short-circuit be caused through the use of the key, since the current must go through the coil in order to be effective. But it cannot pass through the coil unles the switchbar is brought into the right position by the key. The lock is so constructed that the switch-case cannot be removed even after the four screws holding it to the coil box are taken out, except if the key is inserted and in a releasing position. As the lock is of the Yale type and only one key is delivered with each lock there is no chance of a thief starting the car as long as the driver holds on to his key. Of course this type of lock is applicable to any type of ignition system, with only a different arrangement in the installation of the lock. The Automatic Lock Switch is manufactured by the Blackburn Specialty Company, Cleveland, Ohio.

Haco Machine Stand

The Haco motor and machine stand, product of the Hathorn Auto Company, of Mason City, Ia., is made with the object of insuring accessibility in repair work done on automobile engines or transmissions. The stand consists of two upright pressed-steel members, as may be seen from Figs. 2 to 4. A shaft which carries a large wheel at one end is laid across the stand

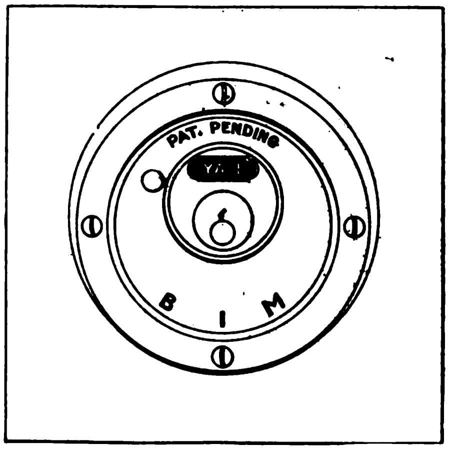

Fig. 1—Automatic lock switch

proper being rigidly fixed at the points of contact with same. A horizontal frame, or rather a working table consisting of several bars, is so connected with the cross-shaft that, if the latter is turned, the working table is moved to an upwardly inclined position, while normally it rests on the two vertical stand members. The cross-shaft may be turned by means of the worm engaging the wormwheel, the worm being forged integrally with a shaft provided with a handle. As Fig. 2 shows, the working table may be brought to any position within 180 degrees, and provision is made for holding it there by locking the wheel. In Fig. 4 the extreme opposite from the position of Fig. 3 is seen so that if the upper half of the engine is up in Fig. 3, access may be had to the lower side of the crankchamber if the working table is titlted to the position shown in Fig. 4. Naturally, the field of this stand is not limited to the work done on engines or transmissions, but may be used as well on most other machine shop jobs.

Slikup Rubber Compound

Slikup, which comes in tins of varying size, is a compound prepared to protect and beautify rubber, especially the running treads of the tires. It is made white and gray, and is applied to the tires by means of a brush, like paint, from which it differs, however, in its composition. When applied to the rubber surface it fills any air holes existing therein and is very effective in preventing sand blisters; at the same time it protects the rubber from the effects of sunlight. Each time the tire is washed a little of the coat is removed, and after some time a new coat must be applied.

Before applying Slikup to the tread, it is thoroughly washed with water to clean all dust, dirt and oil from it. The contents of the can before being brushed on the tread is stirred until it reaches the consistency of a thick cream. Then a flat varnish brush is dipped into it and the stuff is applied to the tire surface. It takes about 45 minutes to dry. The can should always be kept closed so as to keep foreign matter out of it and to keep the solution at the proper concentration, and nothing should be added to the Slikup under any circumstances. If stirring does not bring about the desired change in Winter time it may become necessary to place the tin into a hot-water bath; then the can should of course be closed. Slikup is manufactured by N. B. Arnold, 98 Montague street, Brooklyn, N. Y.

VOL. XXV NEW YORK—THURSDAY, NOVEMBER 30, 1911—CHICAGO No. 22

THE AUTOMOBILE

Lozier Smashes Vanderbilt Record

Mercer and E-M-F Win Light Car Races

1—Ralph Mulford, Who Drove the Lozier to Victory in the Vanderbilt. 2—Hughie Hughes, Who Won the Savannah Trophy in the Mercer. 3—Ralph De Palma, Second in the Vanderbilt. 4—Mulford Winning the Vanderbilt Race

SAVANNAH, GA., Nov. 27—Mulford, in a Lozier to-day won the eighth Vanderbilt cup race, over the famous Savannah course. He covered the 291.38 miles at an average pace of 74.07 miles an hour, a pace which makes all former Vanderbilt cup marks look small.

It is 9 miles an hour faster than any previous race for this American classic and is not much below the famous record recently made by the National on the Santa Monica course, namely 202 miles at a speed of 74.628 miles an hour.

When Mulford had covered twelve laps or 205 miles to-day, his average speed was 74.9 miles an hour, or faster than the Santa Monica pace for the same distance. His performance cannot be classed as an intermediate record as he did not announce his intention before the start of the race to go after the record as required by the rules governing official records.

Ralph De Palma, in a Mercedes, was second, being but 2 minutes 11.32 seconds behind the leader, with Wishart in another Mercedes third, and Grant in the second Lozier fourth. Fifth place went to Parker in a Fiat, the only one of three Fiats to finish.

THE WINNERS

VANDERBILT CUP
Lozier—Mulford
291.38 mi......236:00.67

SAVANNAH TROPHY
Mercer—Hughes
222.82 mi......195:37.22

TIEDEMAN CUP
E-M-F—Witt
171.4 mi.......176:23.34

Much credit was given to Disbrow, in his Pope-Hummer, that ended in sixth place, although losing much time through the breaking of the exhaust valve and from manifold troubles. Two Abbott-Detroit cars of medium horsepower, were running at the finish. No. 9, driven by Mitchell, having finished sixteen of the seventeen laps, when the race was declared off; and No. 17 having completed fourteen laps. Of the fourteen cars that entered, six finished the race, two others were running at the finish and six dropped out.

A Spectacular Race

THE race was most spectacular from start to finish. It came as the big act of the day's program which consisted of three races, two of which, the Savannah and Tiedeman cup races for smaller cars at shorter distances, were staged early in the day, starting at 8 o'clock. The Vanderbilt was not started until these were completed and it was exactly 11:45 when the starter got the first car away. In spite of this late start Mulford had covered the 291.38 miles at 3:45 o'clock.

The setting was perfect in every respect. The weather was clear, a cloudless sky with a fresh breeze making conditions ideal. The big grandstand, seating over 8,000, was well filled, and there were a couple of thousand more in the bleacher stand across the course. The road surface was prepared to the minute. The entire 17.14 miles of the course had been resurfaced and over $15,000 spent in oiling it. The surface in some places was a little soft but the pace to-day was 4 miles an hour faster than that of the Grand Prize race over the same course last year. The course has several turns but they are all banked and on some of these the cars travelled at as high as 65 miles an hour. On the long stretches the capabilities of the cars constituted the only limit to the speed. The crowds were not all confined to the grandstands, scores of picnicking parties lining the home-stretch and other parts of the course that afforded a good view of the racers.

The speed made was higher than anticipated. It was freely stated that the pace would be somewhere between 73 and 74 miles an hour, but few expected it to go over 74. It is much faster than any previous Vanderbilt, the times for which as well as the distances are given herewith:

Year	Distance	Speed
1904	284.3	52.2
1905	283	61.4
1906	297.1	60.8
1907	not held	
1908	258.6	64.3
1909	278.08	62.8
1910	278.08	65.18

The speed of to-day shows what are the possibilities of medium sized cars on a level course with banked turns. It is generally rumored to-day that the Grand Prize cars of unlimited cylinder capacity will not make much better time over this course on Thanksgiving day.

Perhaps the biggest lesson in to-day's race has been the victory of what might be designated stock cars, as compared with specially designed racing machines. Mulford's car was not strictly stock in that the cylinders were bored out 1-8 inch, making them 5 3-8 by 6 inches bore and stroke. The Rayfield carbureter used was fitted with an adjustment of the needle valve onto the steering column and two extra air inlets mounted on the intake and two exhaust valves. The Lozier pair are chain driven machines and have a pronounced racing appearance due to shrouding the radiator by continuing the hood forward beyond it and curving it in. The three Fiat cars were all racing types having intake

and exhaust valves mounted in the cylinder heads. An overhead camshaft is used and the valves and all actuating parts are entirely enclosed by a metal cover, thus allowing all of the parts to operate in oil. They are chain driven machines and are of the same type as competed in the Grand Prize last year but with reduced bore to bring them under the 600-cubic inch classification.

Savannah lived up to its previous reputations in the manner of conducting the event and patrolling the course. The soldiers were out early and not a person was on the course from start to finish. Military passes were granted to officials and photographers, but otherwise not a person crossed the blackened oiled surface. The scoring was done on two large boards, one serving for each end of the grand stand.

Vanderbilt Lap by Lap

Vanderbilt Cup

Lap 1—It was a whirlwind start, six of the fourteen starters setting out to do the distance under the 14-minute mark and they did it. Ralph De Palma, the favorite before the start, set the pace with a lap in 13:33 or 76.5 miles an hour and Patschke in a Marmon was close by in 13:41, with Wishart in another Mercedes, Mulford, Lozier, and Matson, Fiat, close behind.

It was a magnificent opening spectacle. Everybody wondered what the time would be, and when the opening lap was so favorable, everyone looked to the establishing of some new road race marks.

Starter Wagner got them away at 30-second intervals and it was a long 7-minute wait from the time Matson left the tape until the megaphone announced car coming. Down the stretch a white meteor flashed toward the big grandstand turn and Grant in No. 1 Lozier, first away, was first to cross the tape. Behind him came Burman in his yellow Marmon, a literal streak, as it flew down the black polished roadway.

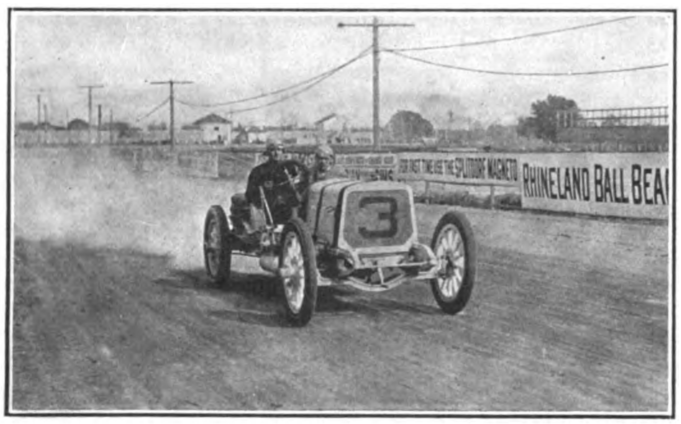
Scarcely had Burman passed the judges' stand than the sombre gray Mercedes No. 4, Wishart, took the curve in arrow-like fashion and was gone. Disbrow, in the Pope-Hummer, was not 200 yards back of him. Then came a wait, seconds seemed minutes and minutes, hours. Eyes were strained into the bushes on the stretch where the black ribbon of road emerged from the foliage. A wait and then a yellow flash, Patschke in his Marmon, came and went. Another glance saw Mulford in his white Lozier, and with white uniform, chase Disbrow.

These five were ahead of the rest of the field. Then followed a wait. Everyone was anxious. Presently, the gray Mercedes, No. 10, of De Palma shot into the curve and was gone. Behind him came No. 9, Jackson, the only time the grandstand was to get a sight of it. It withdrew in the second lap.

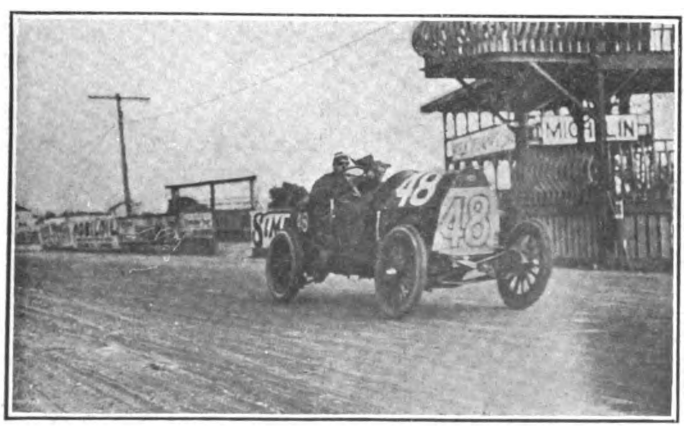
Everybody looked for some of the red Fiats, they all started late, their numbers being 11, 14 and 15. Parker in 11 came first. A blue Abbott was next, No. 9, driven by Mitchell, and then came 15 and 14, Matson, driving 15, having passed his team mate on the opening lap. With all past the grandstand the crowd settled down to watch the scoreboards and see how the struggle progressed.

Lap 2—This was a Mercedes lap with De Palma first, Wishart third and Patschke's Marmon sandwiched between. Mulford

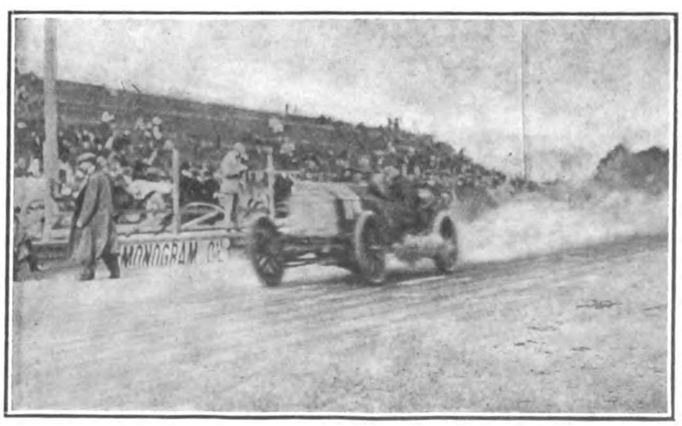
Vanderbilt Contenders in Practice



Harry Grant, the two-time Vandeibilt winner, in his Lozier



Bruce-Brown in the Fiat doing 75 miles an hour in practice



Parker in his Fiat did exceptionally fast work in practice

Grant's Lozier climbing into fourth place and pushing the Disbrow Pope into fifth place. This was the end of a duel between these two cars that had continued practically from the fourth lap. At this point Grant was gradually pulling away, his lead being 11 seconds. At this part of the race Mulford was leading the two Mercedes by 4 and 5 minutes and Grant was 5 minutes back of them. Parker's Fiat was 2 minutes behind Grant.

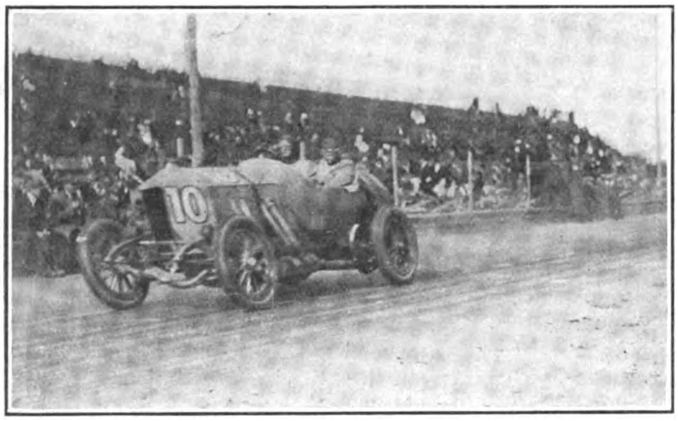
Lap 11—This lap saw Wishart's Mercedes drop from second to sixth place, putting De Palma in second, Grant third, Disbrow fourth and Parker fifth. Disbrow had his trouble in the back stretch and he was 22.45 on the circuit, one of the slowest any of the leaders finished. De Palma made the lap in 13:42 and Mulford in 13:45, both running very closely together. No. 9 Abbott was maintaining its pace by going the circuit in 15:08, a pace of 68 miles an hour.

Laps 12 and 13—Not a change in the position of the contestants occurred in these laps. In lap 12 Mulford stopped 1 minute 6 seconds to change a left rear shoe and took on gasoline and oil. Disbrow stopped to change a left rear, losing 1 minute 35 seconds.

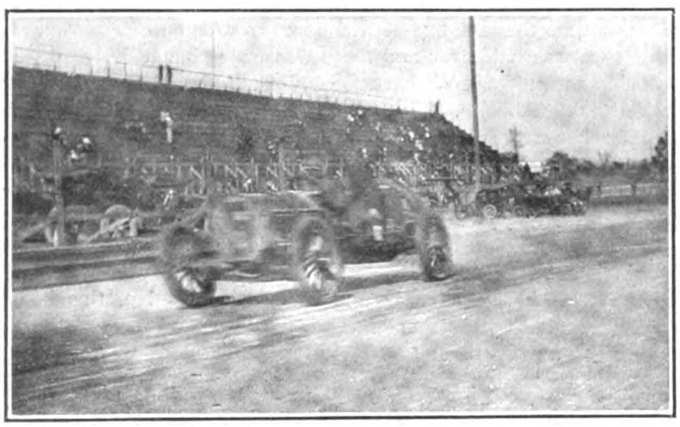
Wishart was traveling fast in these laps and was rapidly cutting down the lead that Grant, in third place, had on him. De Palma was also traveling very fast and, due to Mulford having to stop, had cut his 5-minute lead to about 2 minutes. This marked part of the grand struggle on the part of both De Palma and Wishart to dislodge the leading Lozier. Before stopping at its pit the Lozier had 5 minutes on De Palma, 13 minutes on Wishart, 14 minutes on Parker's Fiat and 13 on Disbrow.

The finish laps, 14, 15, 16 and 17, can properly be considered together because in lap 14 Wishart nosed Grant out of third place and from that to the end there was not a change in the positions of the eight cars that were running. This order was Mulford, De Palma, Wishart, Grant, Parker, Disbrow and Mitchell and Limberg in Abbotts. As told in another place, the fight for first place was between De Palma and Mulford in the four laps.

But with only a couple of laps to go the handicap was too much for the Mercedes. Wishart was firm in third and Grant safe in fourth, having 4 minutes' lead on Parker, who was fifth. Six cars finished the entire seventeen laps and the two Abbotts were running at the finish. No. 9 finished sixteen laps and No. 7 finished fourteen. Six cars dropped out of the race.



Ralph DePalma in the Mercedes finished second in the Vanderbilt



Billy Knipper in a Mercer was a great favorite with the crowds

Story the Pits Told

THE elimination story is never a pleasant one in connection with a road race and in this respect, to-day's race exacted a heavy toll in six cars being eliminated. The causes of all of the eliminations have not been learned to date. The majority of the troubles were due to vibration. Burman, in his Marmon, had magneto trouble; Matson's Fiat broke a radiator trunnion. Brown's Fiat bent the rear axle and then lost a rear wheel; the Mercer suffered magneto troubles. No report was had on the Jackson. Patschke's Marmon had reported motor trouble without specifying any details.

Thirteen stops were made at the grandstand pits for repair,

TABLE SHOWING POSITION OF EACH CAR IN THE

Lozier-Mercedes Duel

THE duel from start to finish between Ralph Mulford and Ralph DePalma was one that will long live in the minds of those who watched the changing conditions. In a word, De Palma took the lead in the race for the first four laps and then Mulford took it for the remaining thirteen.

De Palma led Mulford by 1:10 at the end of the fourth lap which was changed to a Lozier lead of 53 seconds at the end of lap five, De Palma having to change tires on the course and stop at grandstand pits for 2 minutes while tires were put in the rack and oil and water taken on, the result being that Mulford had a lead of 2:06 at the end of lap six. He increased it to 2:14 in lap seven and at the end of lap eight, with the race practically half over, Lozier had a lead of 5:19 and lap nine saw the Lozier's lead increased to 5:29; this was the greatest margin that separated the two cars at any point in the contest. De Palma cut 4 seconds in lap ten and lap eleven saw 2 more seconds cut off. It was a gallant chase that De Palma was putting up and an equally gallant race that Mulford was giving him. Three more seconds were cut off in lap twelve so that at the end of this circuit Mulford had a lead of 5:20. It was at the end of this lap that Mulford slowed down to change a left rear tire and take on gasoline and oil, losing, all told, 1:06. He lost more because the Savannah people were anxious to have him cross the tape so that his time for the distance might be taken. At

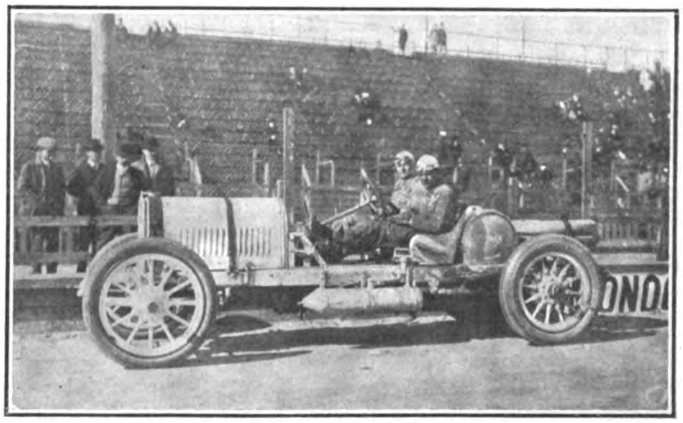
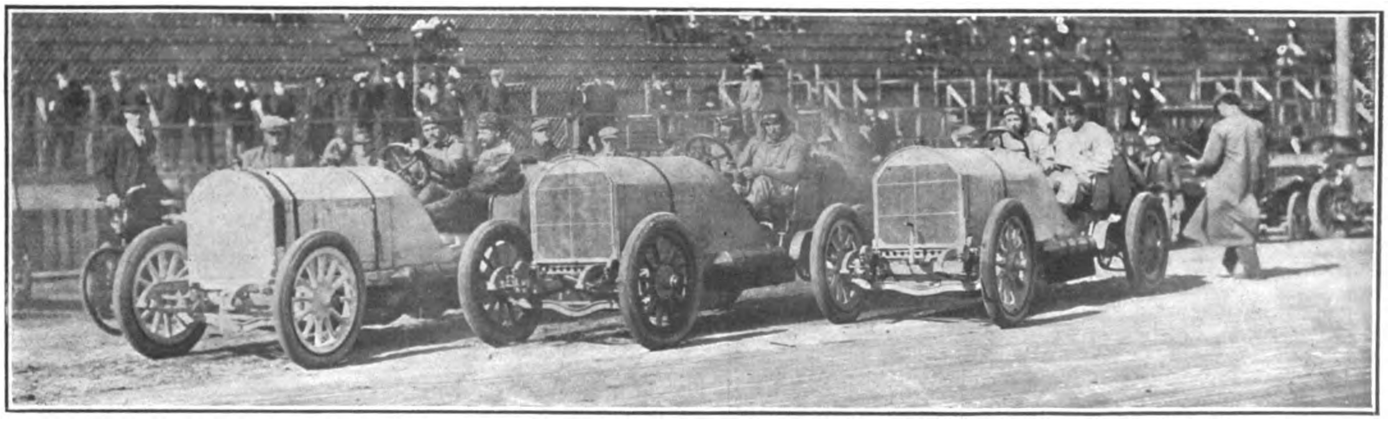
Louis Disbrow giving the word for a time trial of his Case car



Harry Grant poses for the staff photographer before a tryout



The Grand Prize Benz team, composed of Hemery, Bergdoll and Hearne, made a great impression this point he had covered 205 miles and the crowds wanted to know if he had beaten the speed at the recent Santa Monica race which was at a distance of 202 miles.

At the end of lap thirteen Mulford had a lead of but 3:47 on the Mercedes, which was being pushed hard, De Palma doing the lap in 13:27, which proved to be his third fastest in the race.

At the end of lap fourteen the lead of 3:47 was cut to 3:38. Excitement was intense at the end of lap fifteen when Mulford had to stop to put a tire on the rack, which cost him 10 seconds. Taking on a tire meant that he had made a change on the course and he had a lead of but 2:33 with two laps to go.

In spite of changing a tire on the course and stopping at the pit he made the lap in 14:43. Lap sixteen and seventeen were anguishing processions. Everybody wondered, if the Lozier would have to change another tire and, if so, the Mercedes would almost overtake it. At the end of lap sixteen there was 2:07 between the speed monsters, at which time both were given the green flag by the starter, meaning one more lap to go.

The Lozier had a margin of 2.11:28, it having gained 4 seconds on the Mercedes in the last circuit.

Analyzing the Figures

The Mercedes made fourteen of the seventeen circuits under the 14-minute mark, which means over 73.5 miles per hour. The record of 13:14 is 78 miles an hour.

The following are De Palma's laps: 13:14, 13:16, 13:27, 13:32; 13:33, 13.33, 13:36, 13:38, 13:38, 13:42, 13:43, 13:45, 13:46 and 13.50. He had three slow laps, namely; 5, 6 and 7 in 15:39, **15:12 and 17:07 seconds.**

As compared with this **the winning Lozier made thirteen laps** under the 14-minute mark, **the fastest being the seventh in 13:25.** Mulford showed remarkable regularity by doing four laps in 13:41 each and three in 13:45 each and two in 13:38 each. This goes to recall the steady pace held by Mulford during last year's Vanderbilt Cup race.

Mercer Wins Savannah

Savannah Trophy

THE race for the Savannah trophy was started this morning at 8 o'clock and was for a distance of 222.82 miles, or thirteen laps of the circuit. Seven cars started, three Mercers, two Marmons and two Case specials. Hugh Hughes, driving 22 Mercer, won, going the 222.82 miles in 195 minutes and 37 seconds, or 68.04 miles per hour. Heineman, driving a Marmon, was second, being 4 minutes behind the Mercer, and third place was won by Nikrent in another Marmon.

This race was a Mercer-Marmon duel from the fifth lap to the end. Up to the fifth lap, Disbrow driving a Case Special led with Mercer second and Marmon third. Disbrow withdrew in the fifth lap owing to motor trouble and this put the Hughes Mercer into the lead which position it maintained until the end.

The Mercer-Marmon duel was interesting from start to finish. It was not a case of one Marmon contesting against one Mercer, but the three Mercers were waging was against the two Marmons with varying success, although Hughes was never headed off.

E-M-F Wins Tiedeman

Tiedeman Trophy

This race was started at 8 o'clock this morning with the ground white with frost which made it cold during the first few laps. Disbrow started out to burn up the course and would have without doubt been an easy winner had his car held up. He made his first lap 22 seconds faster than his nearest competitor; at the end of lap two he had a 49-second lead over Barnes, in a Mercer; in the third lap his lead was 51 seconds and in the fourth it was 54 seconds ahead of Hughes. Once the Case was out, the race was taken in hand by Hughes, who led to the finish.

While the Case was leading, the Mercers were running second and third with Marmon fourth, and in lap five it was Mercer one, two and three, the drivers being Hughes, Barnes and Knipper. Lap six saw Knipper move to second place and Heineman in No. 21, Marmon, annex third position. Lap seven saw more Marmon gains in that Nikrent driving Marmon 25, passed Barnes. In lap eight it was Mercer, Marmon, Mercer, Marmon, Mercer. Lap nine saw the same order of running continue and Knipper's Mercer was taken out, the trouble not being known. In lap ten the order remained unchanged. Lap eleven saw the Barnes Mercer take second place away from Heineman's Marmon, holding the place in lap twelve, but losing it in lap thirteen, the last of the race, so that when it was over the order was Mercer, Marmon, Marmon, the Barnes Mercer not showing up at the end of the race.

The fastest lap in the race was made by the Barnes Mercer in the eighth circuit in 14:11 or over 70 miles per hour. The winning Mercer made one stop, in lap nine, to take on gasoline and oil and repair a hinge in the bonnet. Heineman stopped for 10 seconds in lap twenty-one to take on a tire to replace one changed on the backstretch.

E-M-F One-Two-Three in Tiedeman

To-day's race for the Tiedeman trophy, ten laps, 171.40 miles, was won by E-M-F machines that finished one, two and three, the only other car running at the finish being the Ford (Kulick). Two Abbott-Detroits were entered, but No. 32 went out in the second lap with a cracked cylinder and No. 31 in the seventh with a broken valve rocker arm. There were six starters and the race was started immediately after the Savannah cup, the first car in the Tiedeman starting 30 seconds after the last of the Savannah.

The three E-M-F cars made a remarkable showing, all finishing within a 3-minute zone. The winner, No. 35, driven by Frank Witt, made the 171.40 miles in 176 minutes and 19 seconds. No 34, driven by Robert Evans, was second in 180 minutes 12 seconds and No. 33 third, in 181 minutes 33 seconds. Kulick, in the Ford, covered the distance in 201 minutes 7 seconds. The fastest lap in the race was made by Mortimer Roberts, in No. 31 Abbott, being 16.23 or 63 miles per hour. When Roberts dropped out in the seventh lap he was 7 minutes in the lead, with the three E-M-F's in second, third and fourth place.

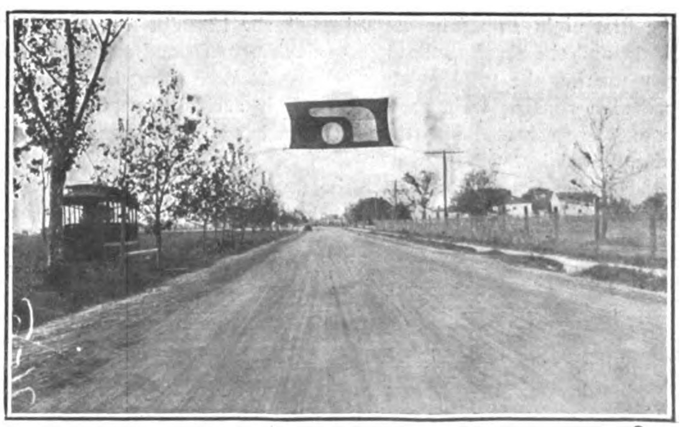
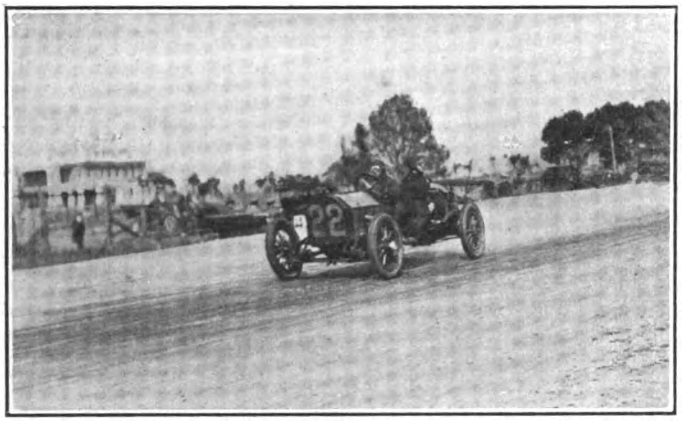
Banked turn into Ferguson Road from Montgomery Road

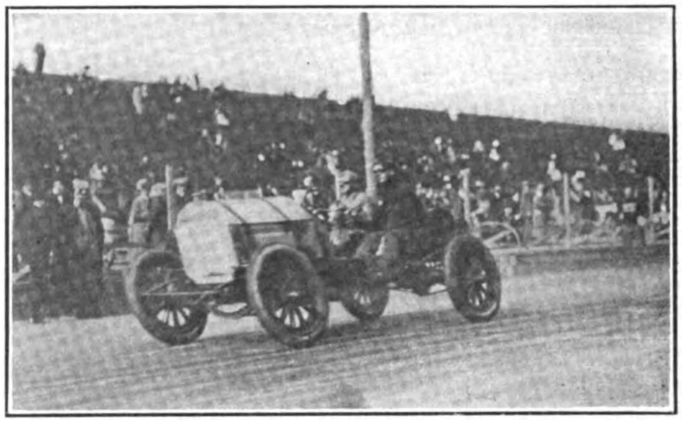
The repair gangs were kept busy right up to the hour of starting



Nearing the end of the beautiful stretch on Waters Road



Nikrent in the Marmon doing a fast lap over the course



Harry Cobe giving his Vanderbilt Jackson a fast tryout

When it came to a race among the three E-M-F machines No. 35 took the lead and maintained it, the other two not changing their places. They all ran consistently, as an analysis of their lap times will show.

The small car races proved most interesting, more interesting perhaps than had generally been expected. The Mercer-Marmon duel in the Savannah was almost as fascinating as the fight between the winner and the foreign contenders in the Vanderbilt race. The fact that in the Savannah race two American teams battled for the trophy, and that Hughes' Mercer that did so much excellent work during the past season, finally finished as the victor did much toward arousing the enthusiasm of the spectators. The victory of the E-M-F in the Tiedeman Trophy event, however commendable, did not come quite unexpected, the car having shown its great strength and speed earlier this year, especially on the Brighton Beach track.

Georgia Tour a Success

Savannah, Ga., Nov. 25—With only two penalizations, both of 1,000 points for withdrawal, the Tour Around Georgia reached here this afternoon, the contestants covered with the white dust of the shell roads of Southern Georgia. The penalized cars are: the Buick, No. 50, which was side-swiped and overturned by a passing car near Americus on the first day's run, and the Dorris, No. 17, which broke a wheel just outside Baxley on the third day's run.

The tourists left Atlanta, Nov. 22 and checked in at Americus, the first night stop. The second day's run brought them to Valdosta and the third to Baxley, to-day's trip from Baxley to this city making the total mileage 502.4. At each stop the cars received a rousing welcome and on their arrival here this afternoon were escorted into the city by a band and a large number of automobiles.

After the Grand Prize race the tourists will make the return trip to Atlanta a two-days' run, checking out here December 1.

Annual Banquet of L. I. A. C.

The Long Island Automobile Club, Prospect Park Plaza, Brooklyn, will hold its annual dinner at the clubhouse on Wednesday evening, December 6. It will be served by a well-known caterer, and arrangements are now being made to have a good vaudeville follow.

Free Entry for Foreign Racing Cars

Washington, D. C., Nov. 27—The secretary of the treasury has informed collectors of customs that the following articles of the customs regulations of 1908 have been amended to read as follows:

"Article 595. Motor cars, motorcycles, etc., and accessories, of foreign origin imported into this country by the owners personally for bona-fide touring purposes only, provided such owners are non-residents of the United States, are entitled to free entry under bond for a stay of six months; provided, however, that such owner shall present at the time of making entry a certificate from the United States consul at the port of exportation, based upon the sworn statement of the owner, to the effect that the said article is brought to this country for touring purposes only and that the same is not to be used for any commercial purposes or business pursuits whatsoever while in the United States. The articles enumerated may accompany the owner or arrive within 30 days before or after his arrival.

"Article 596. Motor cars, motorcycles, motor boats, etc., brought into this country by non-residents of the United States, for the purpose of racing or taking part in other specific contests are entitled to free entry under bond for a stay of not exceeding six months, but cannot be admitted hereunder for display in shows or exhibitions of any kind, nor for any commercial or trade purposes whatsoever. Such purposes shall be evidenced by the oath of the owner or his agent made before the United States consul at the port of exportation and by him certified, and presented at the time of entry."

Self-Starting Commercial Car

Philadelphia, Pa., Nov. 27—The Philadelphia Truck, the latest addition to the commercial vehicle line, was placed on exhibition to-day at A. G. Spalding's on Broad street, above Race.

The Philadelphia truck is equipped with an electric self-starting device, and is the product of the Philadelphia Truck Co.

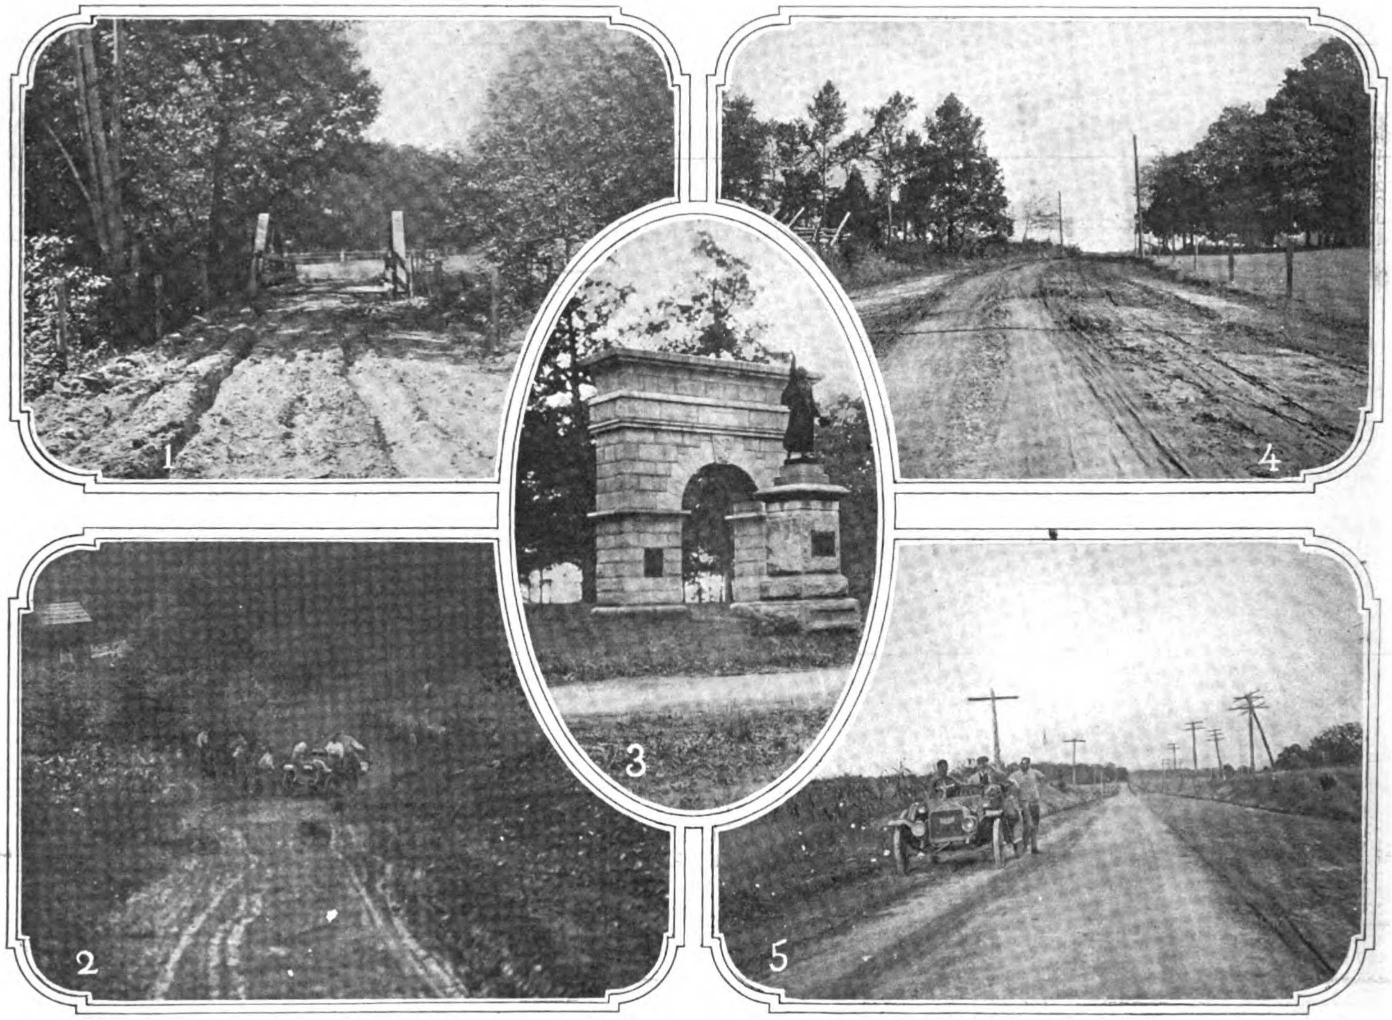
Civic Pride in Davidson County, and



1—One of Davidson County's contributions to Glidden tour misery
2—The State is level, but in the north some heavy grades are found
3—Revolutionary War memorial arch erected on the battlefield of Guilford Court House
4—Red clay road near Oak Ridge, an excellent example of the State roads
5—For 10 miles into Charlotte the macadam roadway is almost perfect

PRECONCEIVED impressions of North Carolina, held by the average Northerner, are far from the mark. Those who have not had the privilege of a recent visit to the Old North State, as it is affectionately called by its residents and neighbors, possess only the most shadowy ideas as to actual conditions that obtain there. In many ways North Carolina is the most advanced of the Southern States. Instead of being poverty-stricken, ignorant and narrow, it is doubtful if better general conditions of living obtain anywhere in the country.

Tobacco, cotton and corn grow abundantly and in high quality almost everywhere in North Carolina; the manufacturing of cloth and yarns and furniture and tobacco is voluminous; retail and wholesale merchandising is large in volume and prosperous and in every way the State is full of life. Needless to say, the roads of North Carolina are good.

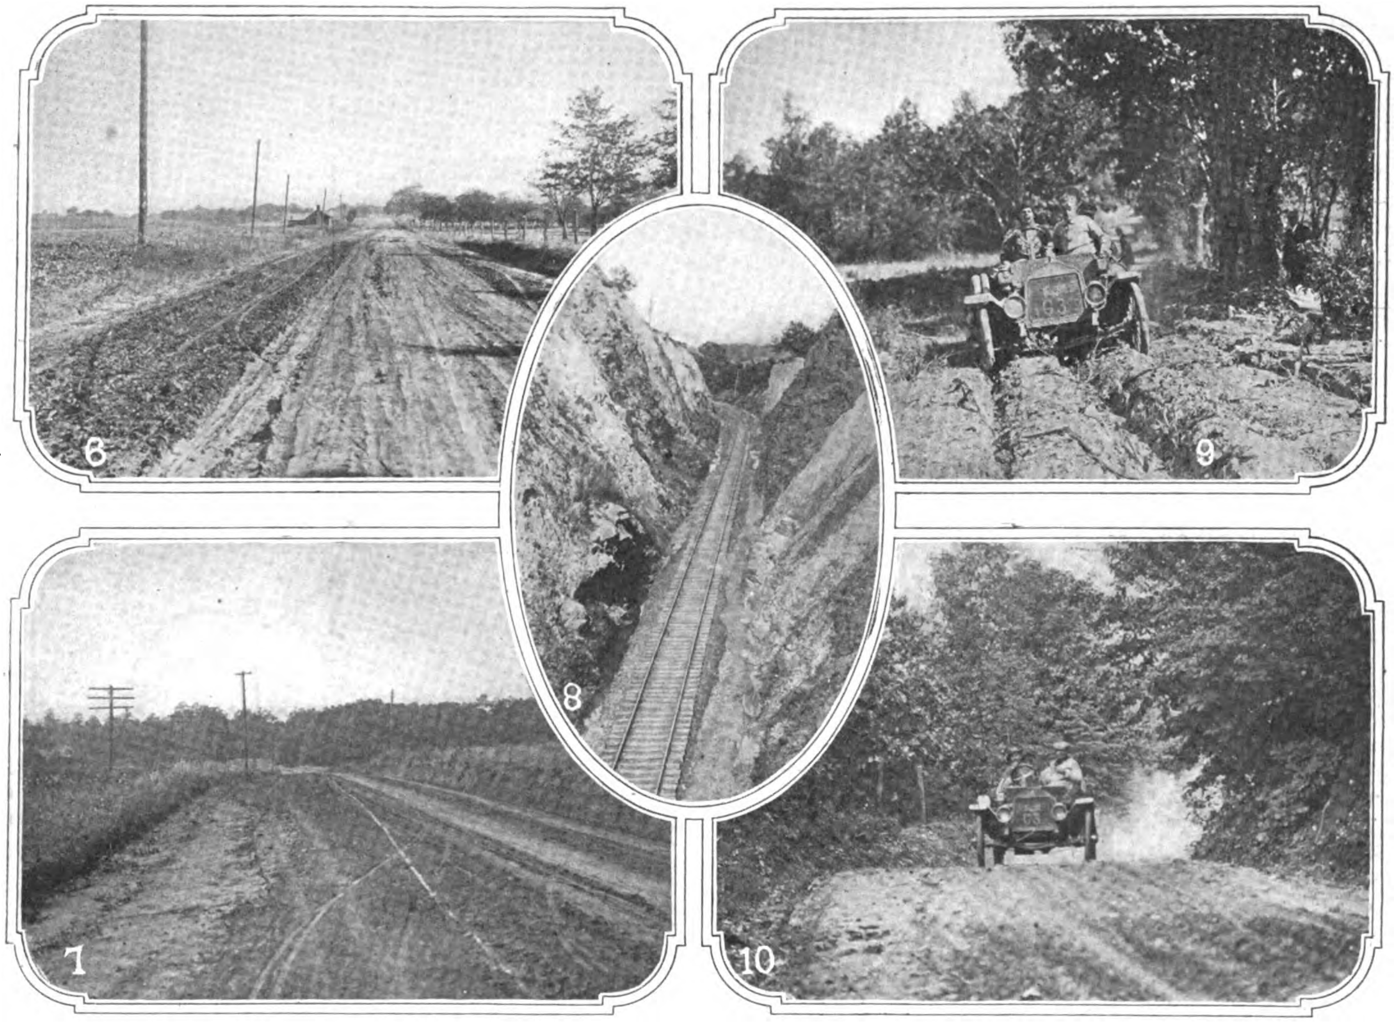
The tobacco mills at Winston-Salem are among the greatest in the world; the furniture factories at High Point turn out a product that rivals Grand Rapids and the cotton mills of Charlotte are stupendous in size and turn-out.

It is said that child labor in the mills is a menace and it probably is, but that is an economic problem and like all other economic problems it can be worked out only through evolution and the general advancement of education. Curious as it may seem the automobile is not in common use. In the big centers of population there are quite a number of cars, but many of the medium-priced lines are not handled at all or are handled in a desultory sort of way not likely to increase their popularity.

In Winston-Salem for instance, where there is abundant prosperity and plenty of money that could be used in the purchase and operation of automobiles, the industry is not what it should be. There is a big field in North Carolina for the agent of any of the moderate-priced lines who will devote as much time and energy to his business as he would have to in any other locality to achieve success.

He has the best argument in the world for making sales—good roads. He has to deal with a real potential buying power, for the money is there. The people understand the value of transportation, because the theorem has been demonstrated to them so often and so conclusively. To the farmer who used to be able to haul a single bale of cotton to market over roadless wastes, no further argument is necessary after pointing out that he can now haul five bales with the same horsepower at much higher speed, using the roads that were born when the automobile came into vogue.

Hotels, Are North Carolina's Needs



6—Example of recently constructed highway south of Summerfield

9—The trip into Lexington is not exactly the best in the world corresponding to the highway improvement

8—Railroad cut through King's Mountain,

7—Here is a typical road scene—this picture was taken near Gastonia

10—Grades and rough spots are to be found in entering Stonesville

The Old North State is at one disadvantage, however, in its road making. Stone is scarce, and as a consequence a mixture of clay and sand represents the commonest and most available surfacing material. This makes an excellent road and with proper grading and scraping at intervals, answers present purposes very well indeed.

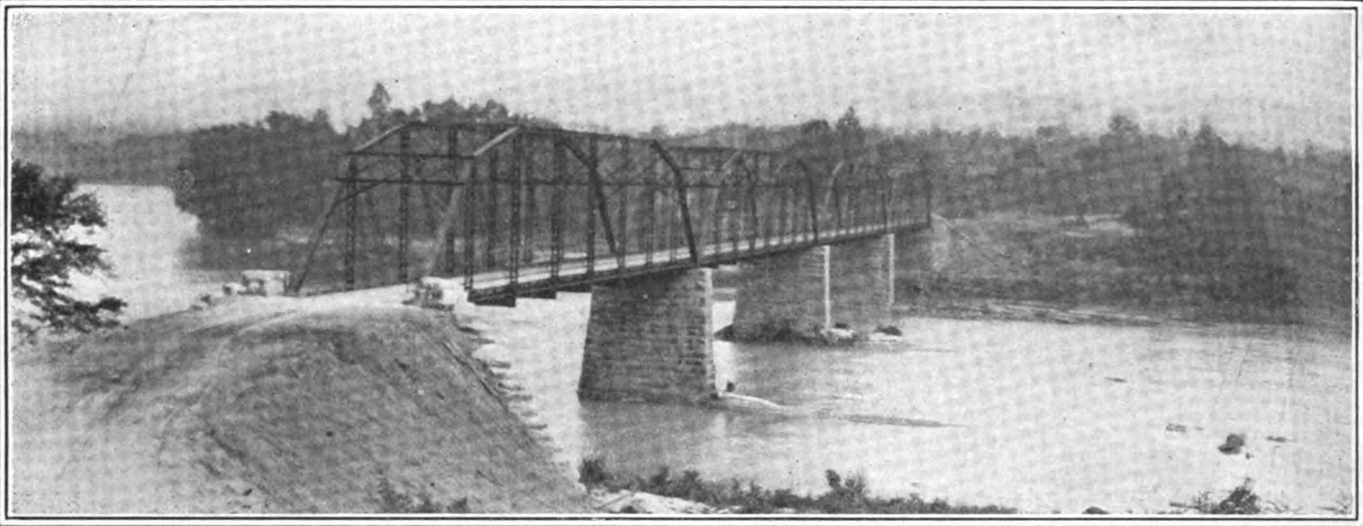
There is only one real bad spot in the State, and it is a disgrace. Davidson County, N. C., will long be remembered by the participants in the recent Glidden Tour for its frightful highways. The city of Lexington, situated in the center of the celebrated Piedmont region, is the county seat of Davidson County. On both sides of Lexington the roads are rough and neglected. No effort has been made for years to improve conditions. There is one place north of the city where the road crosses a savage mud-hole that could be bridged for a few thousand dollars, where traffic is almost impossible. It has been estimated by some of the progressive people of Lexington that this one mud-hole costs the local industries something in excess of $100,000 a year by diverting produce from its natural center.

A bridge costing not more than $4,000 and work on the roads calling for not more than $200 per mile per year, or a total initial expenditure of $6,000 and an annual expense of not more than $2,000 a year thereafter, would mean at least $100,000 more to the city of Lexington. If in addition, $10,000 a year could be used in permanent and current road improvements from side to side of Davidson County to better the main north and south highway traveled by the Glidden Tour, it is as certain as mathematics, that the profits of Lexington would run close to $1,000,000 a year more than they do under present conditions.

Commencing at the Virginia State line, the mileage of the main road across North Carolina to Grover, just north of the South Carolina line, is 237.5, traveling by the way of Winston-Salem, Greensboro, High Point, Thomasville, Lexington, Salisbury, Concord and Charlotte.

All but about 25 miles in Davidson County consists of good roads. Of these probably 80 miles is of domestic macadam of high quality and the remainder is of graded sand-clay roads that are excellent, any way one looks at, or uses them. Generally speaking these roads are 14 or 16 feet wide and smooth as a floor. In wet weather there is just enough traction to make going easy owing to the sand mixed with the clay, and not enough to destroy tires like the average sand road.

The highway enters North Carolina just before reaching Price Station, 48 miles north of Winston-Salem. When the Glidden



Iron bridge crossing the Catawba River after leaving Spurriers

Tour passed that way it was black night and the first few miles into the Old North State were quite a trial. The road is rough for 5 miles. Just plain, rough, but upon coming to Stoneville a gradual improvement is felt. The road broadens and is straighter and all around more agreeable for touring. From Stoneville to Madison, about 7 miles, the improvement continues and after passing the Dan River the highway sweeps to the South practically straight through the pine forests. swerving only occasionally to round some swelling hillock. There is some little sand to be traversed before reaching Stokesdale, 12 miles to the South, but from that point to Kernersville the way is smooth and fine over graded clay roads of the type that makes up most of the way across the State. Kernersville is about 11 miles from Winston-Salem and the road between consists of excellent macadam.

The Gliddenites made a spectacular run from Kernersville to Winston-Salem. The road is generally 20 feet wide and is in excellent condition. Most of the cars were from 10 minutes to 30 minutes late when they passed Kernersville and the wild sprint to control was the big feature of the tour. Lighted only by their headlamps, the caravan picked out the white macadam with ease and as much as 60 miles an hour was made by some of the more powerful contestants in an effort to avoid penalization. The road lent itself to just such a sprint and the sight from the checking station down the long, gentle incline that approached it, was wonderful.

Winston-Salem is the big, virile combination of two cities, Winston and Salem and is one of the liveliest cities of its class touched on the route to the South. Its tobacco factories are gigantic in size and product and it has a sufficiently diversified industry to insure permanent prosperity. As an educational center the place is noted and one of the features of the reception tendered the Gliddenites was the presence of a throng of beautiful girls, students and graduates of the seminaries located there. Winston-Salem has an excellent hotel, something exceedingly rare south of Mason and Dixon's line. It is far in advance of anything encountered by the tourists in Virginia or in fact anywhere between Philadelphia and Atlanta.

Leaving this agreeable place, the route follows the same splendid stretch of macadam to Kernersville that was traversed in approaching the city, but 2 miles further along the road forks and the right fork leads into the main road to Charlotte. Next Spring it is expected that a macadam highway to Lexington via Midway will be completed, which will cut off 50 miles. This road is passable now, but was not used during the Glidden tour.

The macadam, which was left at Kernersville, commences again at Oak Ridge, 7 miles beyond that place, and continues to Greensboro by the circuitous route pursued. This part of the way passes through Summerfield and Guilford Court House, noted as a bloody battlefield of the Revolutionary war. Memorial arches stand upon the battlefield, and in the quaint cemeteries near the little town there are numerous headstones bearing the names

Long, shaky trestle, leading up to a creek in the woods south of Salisbury

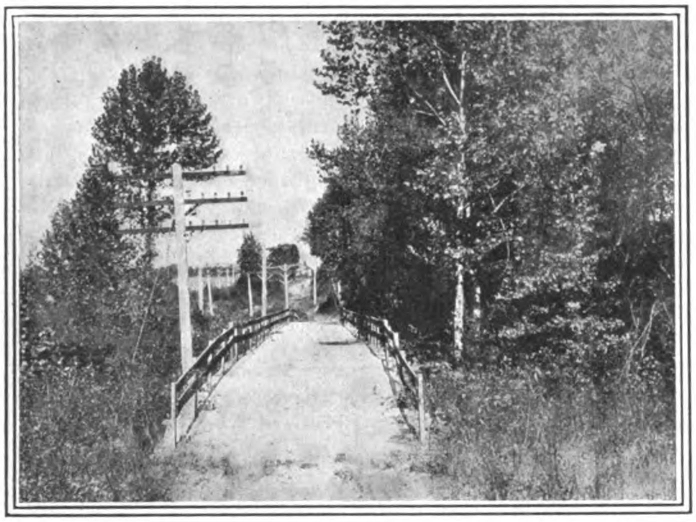
of heroes whose memories are cared for in the rolls of our national history. Here and there among them are memorials to British officers who fell in the big battle and during the campaign that was waged to hold North Carolina to her allegiance to England.

Greensboro is a thriving place which has much manufacturing of various sorts and a rich agriculture. It is one of the best centers in the state for automobiles, as may be surmised from the fact that the roads thereabouts have been awarded first prizes for excellence and a few miles below the city there is a fine, strong bridge that was built by the enterprising citizenship with the prize money that was awarded for their good roads.

High Point, the next considerable town on the route, is 52.2 miles from Winston-Salem by the winding road. This place contains sixty-nine furniture factories and is bubbling full of life and energy. As an instance of its willingness to receive publicity it may be cited that the Glidden Tour was halted for 30 minutes while delicious coffee and sandwiches were distributed through the train of automobiles. Needless to say, the impression created was pleasant. But there are other things about High Point to be commended beside its hospitality. The roads are models of construction and maintenance, the place looks well-groomed and the people seem comfortable. It is said that solid train loads of furniture are shipped from High Point to the wholesale distributing centers of the United States and that the place will prove more and more of a competitor of Grand Rapids in the markets of the world as the years pass.

But after leaving High Point there is a different story to tell. About 3 1-2 miles to the south the macadam ends with a jerk that nearly threw overboard some of the non-cautious passengers on the tour. On the general average the road into Thomasville may be reckoned fair, but after leaving that place, 61 miles from Winston-Salem, the road grows rapidly no better. There is a rather steep climb that commences 6 miles south of Thomasville and continues up and down all the way to Lexington. In the hills the roads are not so bad, but at the bottoms of the inclines the roads were never intended for automobiles, and much less for any other kind of traffic, especially in wet weather.

There is one particularly vicious spot that is encountered 1-2 mile after beginning the climb. The road makes a half circle, following the hillside, and then shoots south across the flat. In the middle of the short stretch that lies between the bottom and the next up-grade, there is a mud-hole about 100 feet across. No bottom was found for this in spots and many of the cars tried to discover it. Broken wheels, steering gear and sprung axles will be the lot of the motorist who tries to negotiate this



Old wooden bridge a few miles out of Winston-Salem on the way to Kernersville

example of Davidson County, N. C., intelligence, without using the utmost care and skill.

This spot absolutely prohibits wagon traffic in wet weather, and the general impression seems to prevail that the reason for its disrepair lies in the fear that a few bales of cotton might be hauled into High Point or Greensboro from points to the south of Lexington, rather than to market in that city. At any rate such cotton will continue to be marketed at Lexington until the mud-hole is bridged adequately, although it is quite likely that thousands of wagon-loads of produce raised to the north of the obstruction will not make any desperate efforts to come to market at Lexington as long as the mud-hole exists in its present condition.

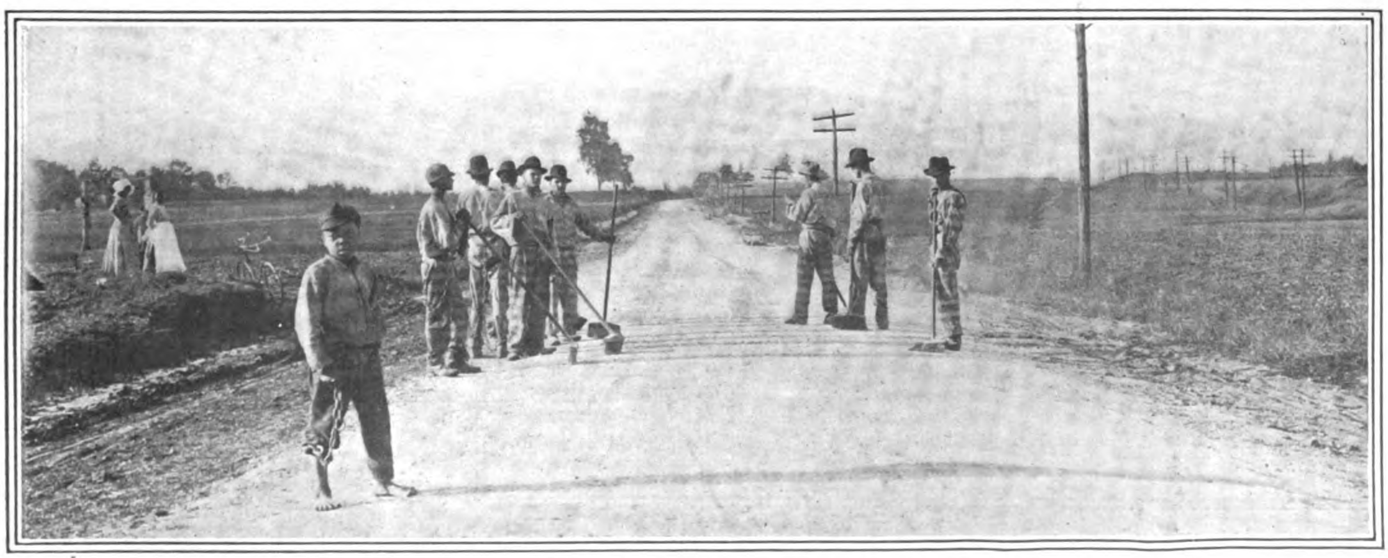
The roads through Davidson County were built by the soldiers of General Greene's army during the Revolution and most of them look as if they had never been touched since that lamented officer passed away. As might be expected, there are numerous fords in Davidson County and a toll gate or two, where the roads are worst.

Salisbury, N. C., is quite a different kind of a place, situated in quite a different sort of a county. As soon as Davidson County is left behind, the roads show a startling improvement. From Salisbury to Concord, a distance of 22 1-2 miles, the route is over graded clay and fine macadam, the latter being found for a mile on either side of all the settlements of any size and continuously for miles on entering and leaving the larger places. Salisbury gave the tour a warm welcome and did its best to make up in hospitality what it lacked in accommodations.

The final 27 miles of the run into Charlotte is notable for the remarkably good macadam roads all the way. For a week prior to the tour a band of convicts was set to work on this stretch of road and when the cars passed it was generally remarked that the road compared favorably with the best in New Jersey as far as smoothness was concerned.

Charlotte is a manufacturing city, developed from an agricultural city. It has good water power and facilities for turning it into electric current. As a result the cotton mills of Charlotte are gigantic affairs turning out immense amounts of cloth and yarns. It is the undoubted cotton manufacturing center of the South. But Charlotte needs hotels. The experience of the Glidden Tour may have been unusual and extraordinary while stopping over night at Charlotte, but it can be said with conviction that nobody connected with the tour enjoyed the stay.

From Charlotte to the South Carolina line is 53.3 miles on the road used for the Glidden Tour, but after next Spring it will be shortened by 10 miles when the detour to cross the Catawba River, using the old iron bridge north of Charlotte, will be eliminated and the river will be crossed just east of Belmont, via a magnificent new concrete bridge that is now being constructed at the scene of Sloan's old ferry, a stumbling block of former years. The roads are fine clear to Bessemer City, being composed of good macadam and nicely improved sand-clay. This is 40 miles from Charlotte and all the way the cotton fields extend as far as the eye will reach.



The macadam road into Concord is as good as any to be found in New Jersey

Franklin Omits Auxiliary Exhaust

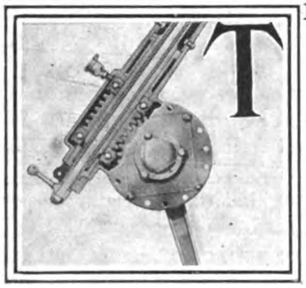


Fig. 1.—Steering detail

THE Franklin Automobile Company, of Syracuse, N. Y., which has just come forward with its latest developments, has not designated the new models by the year in which they are making their appearance, but has departed from this practice and has changed the nomenclature of the different models to a letter system. But few changes mark the introduction of the new cars, the chief of these being the omission of the auxiliary exhaust valve which was located at the bottom of the stroke and through which about 70 per cent. of the exhaust products passed.

The five models which are embraced in the Franklin line include motors of 18, 25, 30 and 38 horsepower, having bores of 3 3-8, 4, 3 5-8 and 4 inches respectively. The stroke of all models is 4 inches and the number of cylinders is four in the case of the first two models mentioned and six in the other two. The details of construction for all four types of motors are similar and a general description of the Franklin motors will fit any of the types manufactured. Where any departure is made from the standard methods it will be mentioned in the following description.

The cylinders are cast separately to provide room for the vertical air flanges, to pass entirely around the cylinders. These ribs by means of which the motors are cooled, are integral parts of the cylinder castings and extend down to the bottom of the combustion space of the cylinder. The valve cages are also parts of the cylinder castings, as may be seen at C, Fig. 2. The cylinders are fastened to the crankcase by means of holding-down bolts B which pass through the flanges at the bottom of the casting and into the upper part of the crankcase. The bottom of these bolts may also be seen at B in Fig. 3. The material from which the cylinders are made is of selected gray iron. The vertical flanges, which are integral parts of the cylinders, are 8 inches in length, 1 inch in depth and 1-16 inch thick, they are set into the cylinder to a depth of 1-8 inch to secure a rigid connection, and are placed at intervals of 3-16 inch entirely around the circumference of the cylinder. An outer covering of sheet metal is placed about the flanges as shown at O, Fig. 2, for the purpose of confining the cooling air to the flanges which form the heat radiating surface.

The cooling air is circulated through the air jacket in a very ingenious manner. A sheet-metal partition is constructed and so placed that it touches the dash, the sides of the hood and the air jackets at about the center of their length, thus dividing the space into two air chambers, one above this partition, which is covered by the motor hood, while the other is below the partition and is covered by the bottom pan of the motor. Between the two air chambers the only possible passage for the air is down through the vertical flanges of the cylinders. A suction fan is located in the flywheel, being formed by the vanes of the wheel. When the motor is in operation the revolving flywheel fan tends to form a vacuum in the lower air chamber, thus bringing currents of the air down from the upper air division which must pass through the cooling flanges to pass into the bottom chamber.

The supply of fresh air in the upper air chamber is unlimited, as it is drawn through a grilled opening in the front end of the engine hood, and since the partial vacuum which is produced in the lower compartment must be equal throughout the compartment, a like amount of air will pass through each cylinder air jacket and the cooling effect on each cylinder will be exactly the same.

Lubrication Receives Special Attention

Owing to the fact that the Franklin motors are required to work at a higher temperature than water-cooled motors the oiling system has been given particular attention. The system used is known as the recirculating force-feed type. The oil is contained in an aluminum sub-base which is bolted to the crankcase and separated therefrom by means of a wire gauze screen partition. In the four-cylinder models the oil reservoir runs the entire length of the crankcase, while in the six-cylinder models the sub-base is beneath cylinders three, four, five and six. The lowest part is beneath the last cylinder, at which point are located an oil gauge, pump and a screw plug for draining purposes. The pump which takes the oil from the reservoir sends it through an individual lead to each main bearing. These leads are exposed as may be seen at L, Fig. 2, in order that they may be readily inspected in case there is any difficulty with this part of the oil system. The oil which is forced through each of these individual leads passes into a groove in the upper half of the main bearing bushings. Another and smaller oil groove intersects the first groove and extends almost the full length of the bushings. A drill hole in the crankshaft communicates with the grooves in the main bearing bushings during out-half of each revolution, and the oil, which is under pressure from the pump, passes through this groove and is carried along into the crank cheeks. The centrifugal force due to the rapidly revolving crankshaft throws the oil into the leads in the connecting rod bushings, the lower halves of which are identical with the main bearings.

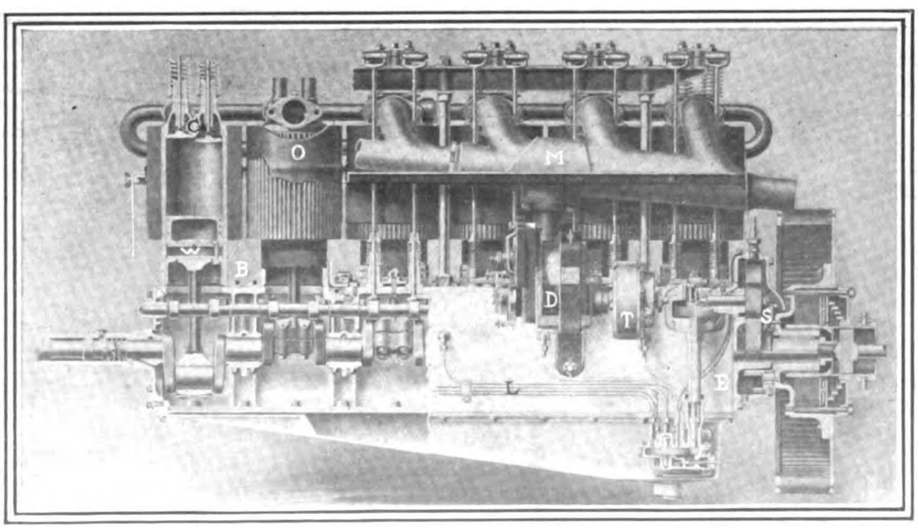

Fig. 2.—Longitudinal view and part section of Franklin air-cooled motor

The oil which is thus carried to the connecting rod bearings is forced out of them

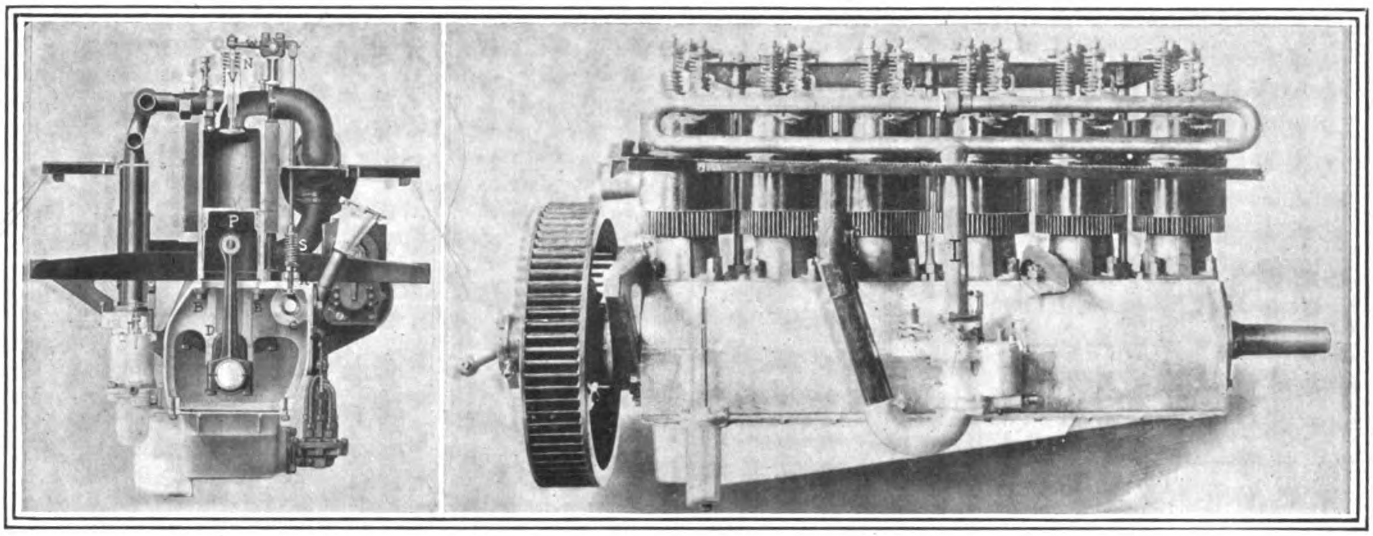

Fig. 3.—Showing transverse section through motor and a longitudinal view of the intake side.

and thrown off the end of the rod in a fine spray which pervades the engine base and lubricates all the moving parts of the motor, including crankshaft bearings, cylinders, pistons and the valve mechanism. The surplus oil drains from the cylinder walls and other interior parts of the motor, and falls down upon the base, where it passes through the mesh gauze and into the reservoir. The gauze strains out any sediment and metallic particles and keeps the oil which passes into the reservoir clean. There is an independent lead E which passes from the pump to a sight feed on the dash. The oil which passes through this sight feed drains back into the rear of the crankcase casting and down over the camshaft, spiral magneto gears and thence back through the wire gauze into the reservoir.

Some Details of Motor Construction

A departure from the lubricating system just described is employed on the Model G runabouts. They are equipped with a multiple force-feed system. Oil is pumped by means of a Hancock oiler to the main bearing.

The reservoir on the Model H and D motors has a capacity of 3 gallons, that on the M 2 1-2 gallons and the G 2 gallons. The Hancock oiler will hold about 7 pints.

The pistons, P, Fig. 3, on all the Franklin motors are fitted with three rings, all of them being above the wristpin. The rings are ground to size and balanced in connection with the pistons. As may be seen in the illustration, the pistons are of the flat-head type and taper in thickness to a point near their lower extremity, where a boss may be seen. A very thin aperture is seen between the wall of the piston and the cylinder in the sectional view. This is for the purpose of catching up the oil from the cylinder wall and distributing it over the upper part of the piston. The wristpin W, Fig. 2, is driven through the aperture in the interior of the piston, and is fixed in position by means of a set screw which passes through it. As the wristpin is hollow and open at either end, a quantity of oil will pass into it which will eventually work its way by means of a duct to the wristpin bearing bushing.

Owing to the method of casting the cylinders singly a main bearing is inserted between each, so that in the four-cylinder models there are five main bearings, and in the six-cylinder models there are seven. These bearings are supported upon bridges which are formed by webs in the crankcase casting. The construction of these bridges may be seen in Fig. 3 at D. The web also forms the basis of the camshaft bearings C and serves generally to stiffen the entire structure.

The valve action is operated by means of a single camshaft located upon the left side of the motor. The valves are separate in the head of the cylinder. The composition of the valves is silico-manganese steel, treated in the electric furnace. Both the intake and exhaust valves are the same size on the D and M models; upon the G, however, the exhaust valve is 1 3-4 inches in diameter, while the intake valve is but 1 1-2 inches. On the model D motor the largest diameter of the exhaust valve head is 1 15-16 inches, with an overall length of 5 15-16 inches. The length of all the valves is 1-4 inch. They are all operated, as may be seen in Fig. 3, by camshaft, the cams of which operate directly upon the pushrod R through the spring S and thence through a walking beam W to the valve stem V. This arrangement is similar to the methods used in former Franklin practice, except that the camshaft is of one-piece construction, being turned down from bar stock, and the cams are integral parts of the shaft.

Valve timing and adjustment is made possible by means of a lock nut which is placed against the walking beam adjusting screw and which is so set that the relative positions of the valve may be changed with the different settings of the flywheel. The fulcrum of the rocker arms is formed by an I-beam support which runs along the top of the cylinders from one end of the motor to the other. The rocker arms touch upon the ends of the valve stems and are held in contact with them by a spiral lifter spring N, Fig. 3, at the base of the valve lifter rod. The rocker arm supports are attached by perpendicular rods to the engine base, so that any variation in valve action, due to the expansion of the cylinders when hot, is rendered impossible.

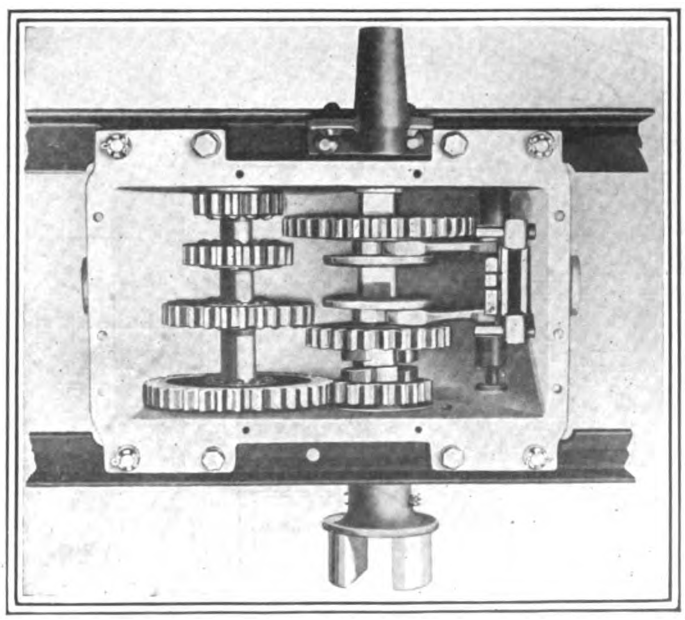

Fig. 4.—Looking down into the Franklin gearset housing with the cover removed

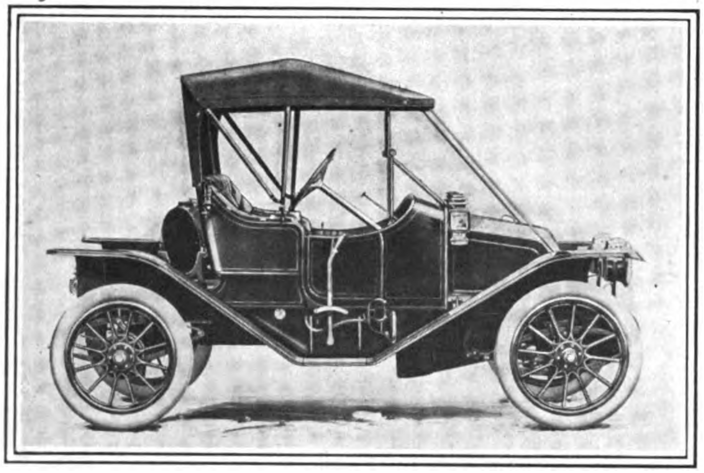

Fig. 5.—The Franklin fore-door roadster showing exterior position of speed-change lever

The carbureter is located on the right side of the motor. It is of the Franklin automatic float-feed type. In the six-cylinder models an auxiliary air intake valve is fitted, which is operated by the suction of the motor. A coil spring keeps the valve seated until the motor pulls more strongly when speeding up, at which time, the suction becoming greater than the strength of the springs, the valve opens and additional air is admitted to the intake manifold. The temperature of the vapor on its way to the combustion chamber may be regulated by a hot-air pipe which draws its supply from a sleeve fitted about the exhaust pipe. In cold weather all of the air taken into the carbureter may be drawn through this hot-air intake; similarly in hot weather the air from the mixture may be governed so that it will not be greater than atmospheric temperature. The carbureter needle valve which controls the supply of gasoline is regulated from the dash. As may be seen at I, Fig. 3, the mixture passes from the carbureter through a vertical pipe which leads into an endless elliptical intake manifold. The vertical pipe enters this manifold on one side while on the other the various leads to the cylinders are fixed. In passing into the cylinders the mixture must go at least half-way around the manifold, so that an equal quantity and quality of mixture is assured to each cylinder. The exhaust manifold M, Fig. 2, is fitted upon the opposite side

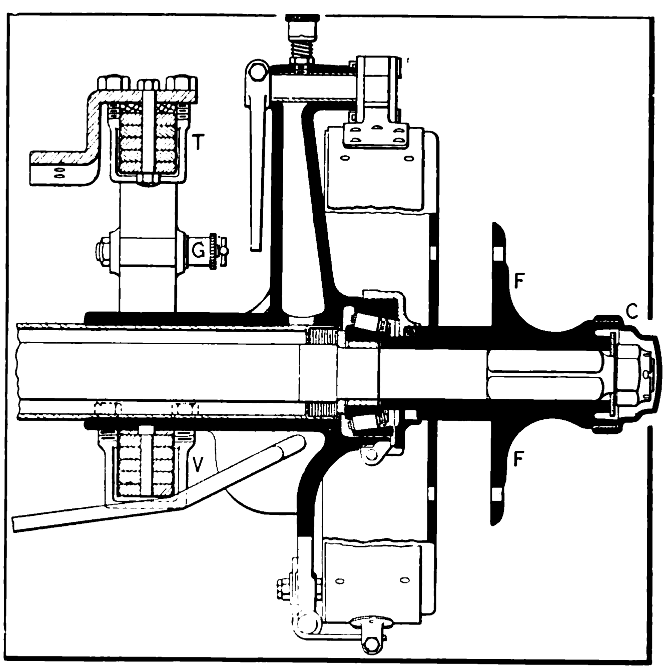

Fig. 6—Section through wheel hub and axle showing brake and spring supports

of the cylinders from the intake, and is of large dimensioned injector type, sloping downward toward the rear of the motor.

Ignition is furnished by the Bosch dual system, a high-tension magneto providing the spark, while a storage battery, which is located in a battery box on the running board, supplies the battery ignition. In order to promote accessibility as far as possible, all the wiring is exposed where this can be done without danger. The magneto is shown at D, Fig. 2, and is driven by the train of spiral timing gears S through the camshaft which runs along this side of the crankcase. The speed of the magneto is regulated by a centrifugal governor operated by means of weights and springs within the drum T. The governor shaft has upon its end, within the drum, a gear meshing with two segments which are a part of two pivoted weights located on opposite sides of the drum. As the governor shaft revolves the two weights tend to be thrown by centrifugal force toward the perimeter of the drum. This tendency is resisted by the spiral springs, which are strong enough to hold the weights in their original position until a speed of about 300 revolutions per minute is reached. At that point, however, the automatic brakes by which the spiral springs are assisted give way and allow the weights to start and move outward toward the circumference of the drum. This motion of the weights will move the drum along the magneto shaft to which it is keyed. This advances the armature and sets the spark ahead, thus providing the proper spark for any engine speed. On the left side of the dash is placed a kick switch, which has in its center a button that may be used for starting on the batteries. On the larger models the ignition timing is controlled by the governor, while on the G runabout it is constant.

The clutch is of the Franklin multiple-disc type and is incased in the flywheel. It is operated by a pedal which works through a small round hole in the footboard. The clutch housing is an oil-tight casing and the clutch runs continually in oil. The facing of the clutch is bronze on the driven members and steel on the driving members.

The gearset is of the Franklin selective sliding type, having three forward speeds and one reverse. It is enclosed in an oil-tight casing which may be seen with the cover removed in Fig. 4. The gear wheels are of specially hardened steel designed for durability. A feature of interest in connection with the Franklin gearset is that the shift lever shaft runs across the top of the gearset casing instead of passing through it. This construction allows of a shifting of gears with a shorter movement of the hand. The gear ratio on the H and D models is 3.75 to 1; on models M and G, 3.71 to 1, and on the G runabout, 3.78 to 1. A threaded plug is fitted in the bottom of the aluminum casing, through which the oil may be drawn off when it becomes necessary to renew the supply. The shafting of the gearset runs upon ball bearings.

Transmitting Power to Road Wheels

The drive is taken up by the propeller shaft through a universal joint which is fitted just aft of the gearset casing. This shaft is of special heat-treated steel and is also fitted with a universal joint at the rear end. Power is transmitted by the shaft into the differential by means of a star pinion fitted to the end of the short differential shaft which runs upon ball bearings in forward end of the differential casing. In passing from the universal joint at the rear end of the propeller shaft into the differential casing this short shaft goes through a packing box which precludes the leakage of any oil from the differential through this joint. The packing box casing is held in position by the bolts D, shown in Fig. 7. The star pinion P engages with the bevel wheel D, which is fastened to the annular wheel W, which in turn drives the two spur wheels S. The latter wheels transmit the drive to the live rear axle A. The differential wheels and shafts throughout run upon ball bearings, indicated by T in the illustration. The ends of the axle shafts are squared so that they may easily be withdrawn by simply removing the hub cap C.

The live axles deliver their power to the wheels by means of a flange F, Fig. 6, which is bolted to them by six bolts. The service brakes are of the contracting type, faced with Raybestos. They operate upon the change-gear shaft. The emergency brakes are also of the contracting type and operate upon bands located at the rear wheel hubs. The emergency brake bands are also faced with Raybestos. The service brakes are controlled by means of a pedal from the driver's seat, while the emergency brakes are controlled by a lever located on the right side of the driver's seat.

The wheels are of the wood artillery type, having twelve spokes both front and rear in all models. The hubs are castings, while the wood used in the construction of the wheels is of second-growth elm or hickory. All the wheels are of standard universal quick detachable type, designed to fit any make of tires. On the Model G touring car the tires to be used are 32 x 4 inches both front and rear. On all other models the rear tire equipment is larger than on the front. On the Models H and D the tire sizes are 36 x 4 1-2 inches and 37 x 5 inches; the Model M, 34 x 4 inches and 34 x 4 1-2 inches; on the G runabout they are 32 x 3 1-2 inches and 32 x 4 inches. The wheelbases are as follows: On the H, 126 inches; D, 123 inches; M, 116 inches, G, 103 inches, and the G runabout, 100 inches.

Laminated Wood Chassis Still Retained

The Franklin company still maintains the wooden chassis which has characterized its line in the past. Laminated wooden sills are the direct support of all styles of body. The front axle is of the built-up type with the knuckle yokes and spring chairs hot riveted to a nickel-steel tube. The knuckle connecting rod is fitted in the rear of the axle tube. The axle is of drop construction. The side members of the frame are of wood built up in laminations, giving a rectangular section. There is no drop in the side frame. Maximum depth of the side members in the Model G runabout is 5 3-4 inches; in all other models a maximum depth of 6 1-2 inches. In all cases the width of the members is 1 3-4 inches.

Elliptic springs are also continued as a feature of this year's cars. On the Model G runabout the width of the spring plates is 1 1-2 inches and the span 36 inches in both front and rear. In the Model G touring cars the width of the plates is 1 3-4 inches, while the span of the springs is 36 inches. In the Models M, D and H the width of the plates both front and rear is 1 3-4 inches, while the span of the spring is in all cases 40 inches. In Fig. 6 the manner of attaching the springs to the chassis by means of U-clips is shown at T and V. Lubrication is provided by means of specially fitted grease cups G which are also shown in the illustration.

The steering gear is of worm-and-gear type actuated by a large steering wheel built up on an aluminum spider. The worm which turns the gear runs upon ball bearings which are adjustable for wear. A section through the steering gearcase is shown at Fig. 1. The throttle control lever is located upon a quadrant situated on the steering wheel spider. This lever actuates a shaft which passes down through the center of the steering column and terminates in a small bell crank lever to which the throttle governing rod is attached. Spark control is entirely automatic and therefore there is no ignition lever upon the steering wheel.

A special accessory fitted to all the new Franklin cars is a gas lock located on the right sill beneath the driver's seat, for the purpose of preventing the theft of the car. In connection with the gas lock valve there is a device for the purification of the gasoline on its way to the carbureter. It consists of a metallic cylindrical chamber located just within the sill and connecting the four-way gasoline valve of the gas lock. Within this cylinder there is a removable screen of fine wire gauze. The gasoline which enters the chamber comes up through the bottom by means of a small standpipe which projects into the chamber more than half-way to the top. The exit of the gasoline is near the top of the chamber and gasoline cannot flow out, therefore, until the compartment is nearly full. Hence, sediment or water will settle to the bottom of this trap and may be drawn out through a cock in the bottom. If it is desired to clean the screen the cover of this chamber may

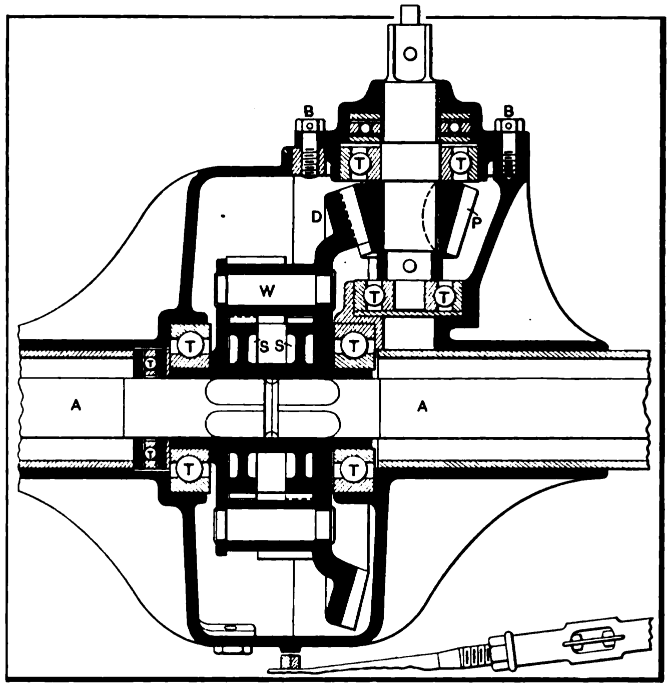

Fig. 7—Showing the differential in sectional view. Note positions of ball bearing

be unscrewed and the screen removed. Among other refinements is a priming rod which projects through the mud apron at the front end of the car. By pulling out this rod the flow chamber of the carbureter is flooded with gasoline so that a rich mixture is procured in case it be necessary to assist in starting the car. Priming cocks are also fitted at the top of each cylinder above the intake valve, through which gasoline may be dropped into the cylinders should it be necessary. A foot accelerator and a muffler cut-out are also a part of the regular equipment, which includes a top, windshield, headlights, tools, storage battery and side and tail lights, the latter on the models H, D and M, being combination oil and electric. On the Model G touring and runabout side and tail lights are adapted for oil only.

Royal blue is the standard color for all touring models, with striping a tint of the same color. Trimmings are black, and black hand-buffed leather upholstery is used. Metal work is finished in black enamel and nickel. The D torpedo model is painted dark tan with tan trimmings, and is upholstered in dark russet, while the M torpedo phaeton is bronze green, with bronze leather seats and cushions. The sloping hood is continued and the fore-door is also a feature of Franklin 1912 construction.

Tesla's New Mechanical Principle

Wide Field for Efficiency Increase in Motor Practice

AN engine which uses gasoline as a fuel and is capable of delivering 60 per cent. of the inherent energy of this fuel at the crankshaft instead of the customary 18 to 22 per cent. has been invented and constructed by Nikola Tesla.

"It is well known," states the inventor, "that a fluid possesses, among others, two salient properties: adhesion and viscosity. Owing to these a body propelled through such a medium encounters a peculiar impediment known as lateral or skin resistance, which is two-fold, one arising from the shock of the fluid against the asperities of the solid substance, the other from internal forces opposing molecular separation. As an inevitable consequence a certain amount of the fluid is dragged along by the moving body; conversely, if the body be placed in a fluid in motion, for the same reasons, it is impelled in the direction of movement."

Based on these observations, Nikola Tesla, the discoverer of the polyphase alternating current, has developed a new mechanical principle broadly applicable for the generation, transformation and transmission of mechanical energy. The machines constructed by Mr. Tesla are illustrated herewith, partly by photographic reproductions and partly by sectional drawings which accompanied Mr. Tesla's original treatise in the *Electrical Review and Western Electrician,* September 9.

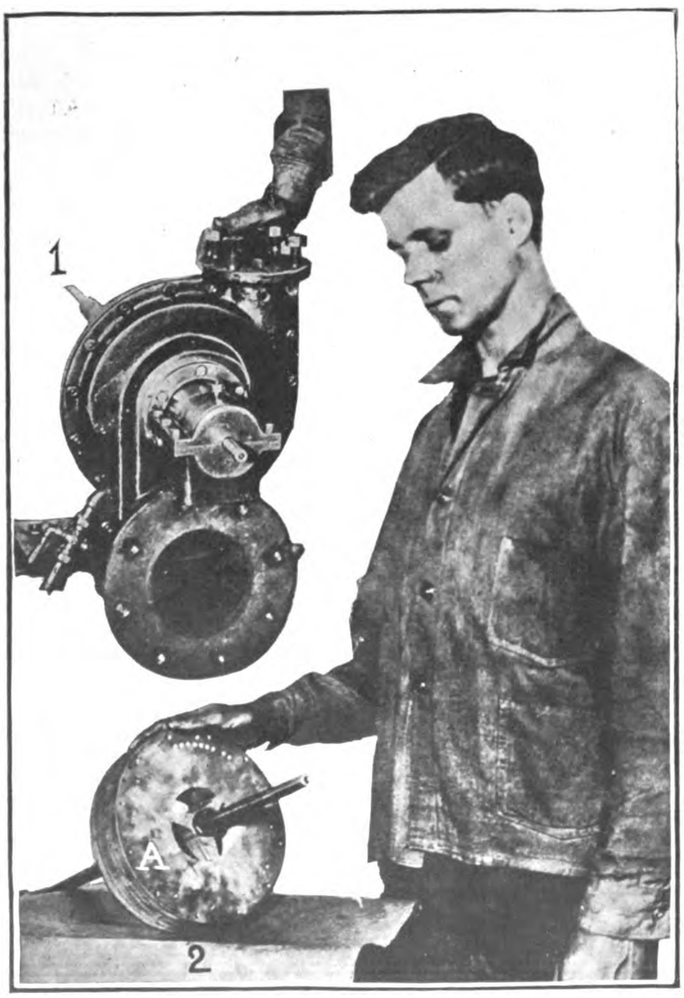

Fig. 1—110-horsepower steam-gasolene engine, weighing 20 pounds. Fig. 2—Shaft and runner of engine

In the development of his machines it has been the aim of the inventor to let the energated fluid *flow along its natural paths;* that is, those of least resistance, with as small a friction loss as possible. It is important to keep in mind the fact that in his, like in all other mechanical devices, *friction is inevitably equivalent to a loss in efficiency.* With these points in view Mr. Tesla uses in his construction but a few simple and economic elements creating as little resistance as possible for the fluids moving his machine or moved by them.

The machine, Fig. 1, is of simple construction and may be used as a motor or as a pump. In a steel housing, very much like to that of a centrifugal pump, is contained a runner consisting of a number of steel or bronze plates arranged in series upon a shaft, Fig. 2. Each plate or disc has three central openings A extending from the shaft to about one-third of the radius and separated by spokes. These openings are cut or stamped out of the discs and the surfaces of the latter are kept as smooth as possible.

If the device, Fig. 2, is mounted on bearings and rotated at considerable speed the following phenomenon takes place. The air, in direct touch with the metal discs, is held to them by molecular adhesion, clinging to the metal surfaces as water does to that of a solid it is brought in contact with, and therefore the air particles next to the discs are imparted motion in the direction of the rotation of the discs. Thus, some air is dragged along and its particles begin revolving about the shaft of the device. Since the movement of the air is rotary, centrifugal force causes it to move away from the central portions of the discs, the resultant between the rotary and centrifugal force being along a spiral line. This flow of air toward the periphery of the discs causes a fall of atmospheric pressure at the central regions, and these being occupied by the openings, air rushes in through the openings, and thus a continuous flow of air is maintained.

If the discs are enclosed in the casing seen in Fig. 1, and the shaft is rotated, the unit will work as a pump. In order to explain the office of the inlet and outlet pipes seen in the illustration, Fig. 3, is offered to illustrate the Tesla pump in partial end view and vertical cross-section. The air adjacent to the discs is dragged along in the direction of the arrows, approaching at the same time the periphery of the discs. In addition to this the particles not in direct touch with the discs, but with the moving air, are dragged along and imparted motion through viscosity, that is, the attraction of the particles of a fluid. The viscosity of air is about 100 times that of water. Thus, the entire body of air between the two discs—unless they are spaced too far—is transported to the peripheral portions of the interdiscular space and, after having reached the periphery, streams along the wall of the casing, which widens from the point 1 to 2, 3 and 4, until the air reaches the outlet where it is discharged. The quantity of the fluid propelled through this pump, according to tests made by its inventor, is approximately proportionate to the active surface of the runner—the total active surfaces of all the discs on the shaft—and to the effective speed of the machines; therefore, the performance of the pump is bettered with increasing size and number of revolutions per minute.

The machine, Figs. 1 to 3, has twenty-five plates 9 3-4 inches in diameter, the entire runner being 2 inches thick and the full weight including the casing of the machine being 20 pounds.

If a fluid under pressure is permitted to enter the casing through what is marked outlet, Fig. 3, it will flow along the wall of the casing, passing the points 4, 3, 2 and 1 in the order named until, when it reaches the narrowing near the outlet, which now is the inlet, it is forced to enter the interdiscular space. In doing this the adhesion of the discs to the fluid causes the former to have motion imparted to them, so that they begin to rotate, while the fluid, which is continually giving off energy, loses in velocity. Since bodies having rotary speed imparted to them are subject to a centrifugal effect, and bodies expending energy in creating rotary motion, to a centripetal one, the fluid with decreasing speed approaches the center of rotation, and is discharged dead, without pressure, through the central openings of the discs. It is exhausted by gravity through the opening marked inlet, Fig. 3.

The engine so described, when driven by a mixture of steam and the products of a gaseous fuel burned in an auxiliary chamber showed 110 horsepower on the brake, and more load could have been sustained by it except for the small dimensioned shaft. While this instance shows that the same machine may be used as a prime mover and as a pump, it is obvious that a machine of this type specially constructed for the purpose of driving machinery may be improved upon by adapting some details to the specific needs of the situation. Thus Fig. 4 shows a Tesla rotary engine, applicable for steam or hot-air drive, having a nozzle through which the pressure of the driving steam is increased. A reversing nozzle is also provided.

As in the other engine the runner is composed of discs D, having central openings O and spokes S. The discs are held in position, being keyed to shaft S_1 which is mounted on suitable bearings. Washers W, conforming in shape to the spokes and riveted thereto, separate the discs. For simplicity's sake, only a small number of discs is shown, with proportionally larger intervening spaces than are used in practice. The runner is mounted in a casing having two end castings S with outlets E, stuffing boxes B and a central ring R_1 bored out to a circle of diameter slightly in increase of that of the discs. The ring has flanged extensions with inlets into which nozzles N are inserted. Circular grooves G and labyrinth packings P are provided on the sides of the runner.

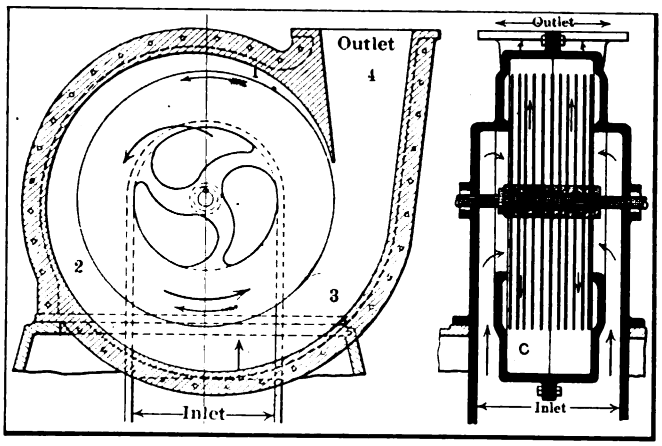

Fig. 3—Cross-section of Tesla rotary engine and pump

A steam engine of this type has been installed and tested at the Waterside station of the New York Edison Company. The runner consists of twenty-five discs, diameter 18 inches, the engine base being 20 by 25 inches, and the height 5 feet. This engine developed, with steam admitted at 125 pounds pressure and exhausted at 14.7 pounds, 200 horsepower at 9,000 revolutions. About 38 pounds of saturated steam were needed per horsepower-hour, but Mr. Tesla stated that by the use of moderately superheated steam and the ordinary vacuum the consumption may be reduced to about one-third of the quantity stated.

If the motor runs without load, the fluid which enters at the periphery completes a number of circles before it has expended all its energy and it leaves through the central openings. As soon as the load is put on, the paths of the fluid are cut short, being

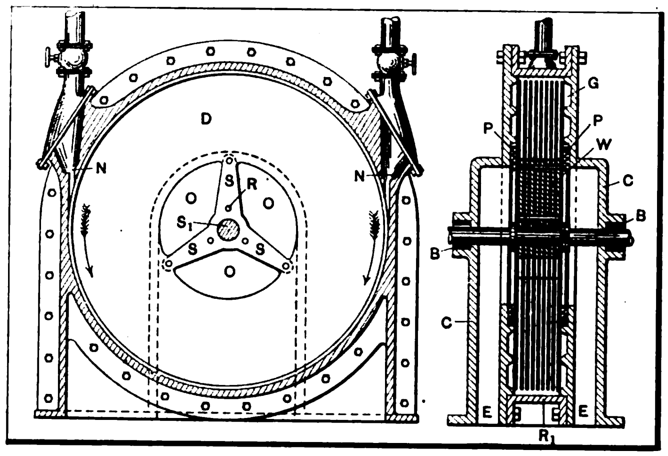

Fig. 4—Cross-section of Tesla engine for reversible steam drive

changed to a spiral with fewer turns. Despite the difficulty attending the work of determining the operating conditions in this machine, the following seems to be an established fact. The torque produced by the engine is directly proportional to the square of the velocity of the fluid relatively to the runner and to the effective area of the discs, and inversely to the distance between the individual discs. The maximum amount of work is done when the effective speed of the runner is one-half that of the entering fluid.

There is no unsurmountable difficulty in the construction of a light and practical motor of this type for the use of liquid hydrocarbon fuels. Of course, an auxiliary combustion chamber and carbureter have to be used in connection with the rotary engine described, and a very small pump to supply the air to the gasoline, if such be used. Mr. Tesla states that he has carried out numerous experiments along this line, and by the use of his motor transforms 60 per cent. of the energy of the gasoline into mechanical work available at the shaft. This may seem very high, but since with a rotary engine (compare steam engines and turbines) it is not necessary to encounter such vast cooling losses as in common gas engine practice, the high efficiency claimed by him might perhaps be obtained even in an average gasoline engine of his construction. It has been shown in THE AUTOMOBILE, July 27, 1911, pages 147-149, that the cooling losses in an automobile engine amount to 35.9 per cent., and the heat losses in the exhaust to 35.2 per cent. These heat losses together with other small expenditures of energies leave only 21.8 per cent. available at the motor shaft, that is, one-third of what is said to be recovered by an engine of the Tesla type.

The possibility of the enormous power output of Tesla engines in proportion to their weight may be understood when the great amount of active surface of these engines is considered. This fact also accounts to some extent for the large thermal efficiency. The 110-horsepower motor weighs 20 pounds, or 5.25 pounds per horsepower; the 200-horsepower engine at the Edison company's station weighs 400 pounds, or 2 pounds per horsepower, and by refinements of construction, the application of superheated steam and the use of vacuum exhaust Mr. Tesla expects to succeed in the building of an engine weighing 1-4 pound per horsepower.

A comparison between a Tesla pump and an ordinary pump may be of interest and not out of place here. In the laboratory of the inventor a small pump of the construction here illustrated is working. It is operated by a small electric motor, consuming 1-12 horsepower, and delivers 40 gallons per minute against a 9-foot head. The consumption of a good centrifugal pump rendering this work is about 1-3 horsepower, and in no case less than 1-4. This means one-third the power consumption for a given amount of work to be performed. As to the application of Mr. Tesla's principle to prime movers, it is stated by him that in large machines, by the use of superheated steam, high vacuum and the minimum of friction obtaining at these dimensions, about 95 per cent. of the fluid energy of the steam are delivered at the shaft.

System Facilitates Car Repairs

Complete Set of Cards Necessary in Handling Repair Work from the Time the Car Enters the Shop Until It Leaves

Peerless Motor Car Company
Test Report

Date Sept. 23, 1911

R. O. No. 4316
Car No. 2795
Owner Dr. Ad. Fisher

Engine	Overheats at high speed. Backfires at advance of 70.
Comm./Mag. Gov., Carburetor	rich mixture
Clutch and Clutch Couplings and Foot Pedals	O.K.
Transmission and Gear Shifting Levers	noise on second
Steering Gear Fore and Aft Rods	O.K.
Universal Joints and Prop. Shafts	O.K.
Distance Rods, Torque Rods	O.K.
Diff. and Pinions	O.K.
Water Pump	test for high speed
Oilers	give too much oil
Dash and all Wires	O.K.
Spark Advance	O.K.
Front Axle and Steering Joints	trace of play at Rector
Emergency Brakes and Foot Brakes	foot brake slips for about ½ wheel
All Wheels	O.K.
Starting Crank	O.K.

Fig. 2.—Repair order sent to shop

GRANTING that speed of execution is a very desirable factor in shop operation, practice has demonstrated that only a thorough training of the workmen and systematic regulation of their operations will make the attainment of this end possible. Just as the half-dozen men serving a gun on a battleship must move rapidly and each man unfailingly fill his office, without ever colliding with his neighbor, so success in the operation of a large machine or repair shop is impossible without systematically directing the operation of every man engaged in a place of work. Moreover, the men must become accustomed to the system, so that after habit has become second nature with them, more and better results are obtained without increasing their efforts.

Division of labor is the key to efficiency and speed increase. According to this principle, an automobile turned over to the repair shop for complete repairs of the broken or damaged parts is submitted to a series of operations, each being performed by a man or men specially adapted for their work through experience along that specific line.

The manner in which repairs are handled by the Peerless Company, 1758 Broadway, New York City, is described. The system used has been worked out to minute details in many respects, but no trouble is being experienced in making the force utilize the system to advantage. The case here treated is that of Dr. Ad. Fisher's automobile, No. 2795, which he ordered to be put in good working order.

Although the owner specified some of the trouble which he noted on his car during its recent operation, the car after being turned over to the Peerless people was taken by the tester and given some 20 miles of road test. This developed all the symptoms written on the card, Fig. 1. The tester or his assistant made a note of all the suspicious points in the behavior of the car, and when machine and operator returned to the shop the test report, Fig. 1, was filled out. The troubles discovered in the engine, carbureter and gearbox were noted concisely, not forgetting the troubles of water pump and oiler. Dawson, the tester, after finishing and signing this report, handed it to the superintendent of the repair department to whom he turned over the automobile at the same time.

The superintendent then drew up the repair order, Fig. 2, No. 4316, and attached it to the steering wheel. The car was delivered to the machine shop, and before any of the real work was started upon it all the accessories were taken off and checked in by a boy, who placed them in a locker. This operation was described in detail in THE AUTOMOBILE, issue of November 23, page 914. Each accessory was provided with a small tag, Fig. 3, on which the repair order number, the number of the car and the owner's name appeared. Then the machine was turned over to the workers for overhauling. The men doing this work strictly adhered to the orders specified on card, Fig. 2, and checked by means of their service cards, one of which is shown in Fig. 4. This card is that of the man who took charge of the repair work after the engine had been cleaned and tuned up. The worker's name was entered on the upper left corner, and under Description of Work all the items were stated, which went to fill the time that he spent on the job. The order number of the repair which occupied him was the same, No. 4316, on all the items appearing on his card. To fix the time spent on each card, it was punched under Job Time. Two lines' space were given to each item of work, and on the upper line, marked A, the starting time was marked by means of a time punch, while the finishing time was noted on the next line under O. The interval between the two times was entered under Payroll Hours. If all the work were done during the regular working hours, the hours and minutes taken up by each job would have been entered under heading Regular Hours. It took J. H. Brown 1 hour and 8 minutes to adjust the carbureter, while the inspection and repair of the transmission took 3 hours 27 minutes. Time spent on testing and adjusting oil and water pumps amounted to 2 hours 42 minutes. Brown started the job when he came in in the morning, but Time came on before he had finished the radiator test, and since the car overhaul should be finished on that same day, he had to put in overtime on it, which amounted to 1 hour 50 minutes, 10 minutes being spent on the radiator and the rest as marked.

Having finished his share of work on the car, he turned the automobile and his own card over to the foreman of the machine shop, who then attached the card, Fig. 5, and sent it on to the paint shop. Work was done in the paint shop on the following day, and after the newly painted sections had dried, the automobile traveled to the trimming shop. Both in the paint and trim shop the workmen used a card identical to Fig. 4, and when they were through with their work the complete card, Fig. 5, was signed by their respective foreman and then turned over to the superintendent.

The office of the repair department is kept in a corner of the machine shop, and after everything ordered by the superintendent had been done, the car was returned to him after the accessories had been attached. At the same time the superintendent received a blue sheet adapted to fit into a binder. On this sheet the whole history of the car in the shop was entered, together with a record of labor and material used on it. The other cards were kept on file in the shop office. From the blue sheet the bill was drafted in the office, which was later on handed to the customer together with his car.

However, before the machine was delivered to its owner it was given a still more thorough road test than the one it received before entering the shop. The tester was not the same as in the preliminary test. If the same man had been on the job he would have kept a very sharp lookout for the troubles he formerly discovered, and if anything had not been repaired to his satisfaction he would have turned the car back to the shop. On the other hand, the man conducting the preliminary test might have overlooked some trouble or other which another man might have discovered in a final test. Dr. Fisher's car was found all right by the final tester, who signed his name to the card before delivering it to the superintendent. The superintendent put the final O. K. on the card, which stated that the automobile was in good shape and ready to be delivered to its owner.

This system, embracing quite a number of cards, is not complicated. Every man writes out but one card at most, passing it on to the next man, until everything comes back to a foreman or superintendent. By having everybody trained to the system, the Peerless company has succeeded in conducting its repair department on a very efficient basis and in satisfying its New York clientèle, both as far as the speed and quality of the repair work done are concerned.

Harking Back a Decade

FROM *The Motor Review,* November 28, 1901:

At the race meeting held at Oakley track, Cincinnati, on Monday, R. Meyer won both events for gasoline cars. He defeated Max Fleischmann and Carl G. Fisher in one and Carl G. Fisher and H. W. Summer in the other. The best time he made in a 5-mile event was 8:32 3-4.

The following officers have been elected by the N. A. A. M.; S. T. Davis, Jr., president; E. P. Wells, secretary; Percy Owen, treasurer; A. L. Riker, first vice-president; C. J. Field, second vice-president; D. E. Rianhard, third vice-president.

Ralph Temple, of Chicago, has added the White Steamer and the United States Long Distance automobiles to his line, which already contains the Oldsmobile and National Electric. Temple's establishment is the largest in the city of Chicago.

C. B. Shanks is confident that he will succeed in driving a Winton automobile from the Atlantic to the Pacific next Summer, despite the obstacles that have stood in the way of such a feat. He will carry a letter from General Shafter to General Miles.

A station for the sale and care of Oldsmobiles exclusively has been opened at 138 West Thirty-eighth street, New York. The first shipment of forty cars is expected to reach New York next week. Its full allotment is 1,000 cars. R. M. Owen is in charge.

George N. Kendall, a retired manufacturer of Orange, Mass., has driven his Grout car for the past season, making 1,001 miles all told. Mr. Kendall says he never drives faster than 8 miles an hour and that the total cost of operation has been $15, or 1 1-2 cents a mile. Mr. Kendall says that if others would use their cars as he does there would be fewer frightened horses and accidents.

Milwaukee, a city of 300,000 inhabitants, has only a single automobile store. This is the Oldsmobile branch.

Automobile exports for the week ending November 20, from New York, amounted to $22,500.

Peoria, Ill., has passed an ordinance barring automobiles from the public parks of that municipality.

The projected race from Paris to Vienna now seems to be a certainty for next year. Objections to passing through Alsace-Lorraine have been made by some of the prospective French entrants and the route will likely be through Switzerland.

Digest of the Leading Foreign Papers

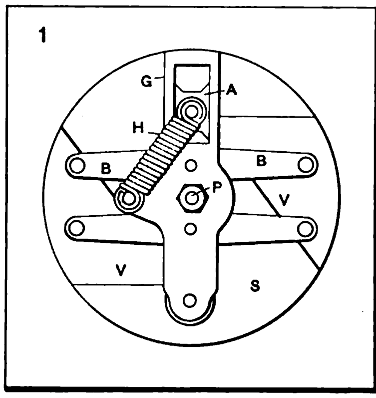

Fig. 1.—Timing the break of primary current

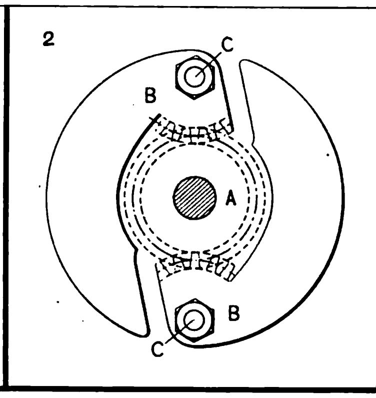

Fig. 2.—Turning armature by swinging weights

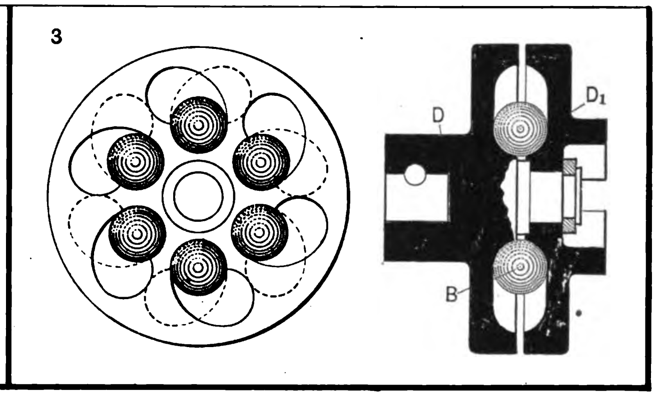

Fig. 3—Curved sockets in multiple ball coupling of the Ruthardt Magneto

Automatic Magneto Timing

ENGINEER A. BERGER of Berlin gave a synopsis of the methods employed by various magneto makers to effect automatic advancement of the spark and thus dispense with the timing lever on the steering wheel. The observations refer to the ignition apparatuses exhibited at the recent automobile exhibition in Berlin.

The recent improvements in automatic spark timing may be ascribed to the strong competition among manufacturers of ignition devices and the necessity for appealing to the convenience of the automobile owner in the sale of their products. The centrifugality of rotary masses is the force employed by all to bring about a change in the timing. Unterberg and Helmle change only the time for breaking the primary current. The diametrical piece G, Fig. 1, which rotates with the armature shaft, carries the platinum contact P and is formed with a radial slide in which the centrifugal mass A works against the resistance of the helical spring H. The leaf spring B pulls the back of the mass toward the stationary plate S. If the mass passes the cutouts V in this plate, the platinum points come for a moment in contact under the influence of the leaf spring B. But the edges of the cutouts, which determine the interruption of the primary current, do not extend radially but at a suitable angle, and ignition therefore takes place so much earlier, the farther the centrifugal mass is removed from the center of the device.

In all other magnetos it is the position of the armature, with interrupter, in relation to the drive shaft of the magneto, which is adjusted. In the Bosch and Eisemann apparatuses the required movement is, as well known, effected by relatively large centrifugal weights causing a sleeve to slide outward on a high-pitch thread, offering an increasing resistance in the direction of rotation.

In the Mea apparatus a small spurwheel A, Fig. 2, upon the drive-shaft meshes with teeth D on the centrifugal weight BB, so that the latter when swinging around spindles C advance the armature shaft with which they rotate. The irregular back pressures arising from the inequalities in the armature drag are not in this case, as in the other constructions referred to, counteracted by any special provision for automatic brake action, but are absorbed in the inertia of the masses. On the other hand, it may be mentioned as an advantage that the resistance of the armature at starting of the motor assists the retaining springs for the centrifugal masses in producing a late spark.

The Ruthardt construction, Fig. 3, is notable for being applicable to any magneto, being placed in the market as a separate coupling between the drive-shaft and the armature shaft. A disk D fixed upon the armature shaft which is swiveled in the drive-shaft is driven by means of a disk D^1 similarly secured to the latter, the driving connection consisting of six steel balls B placed in curved grooves formed in the disks. These grooves are of opposite curvature, when the device is assembled, as indicated by the dotted lines. The driving resistance tends to wedge the balls into the position nearest the center, and centrifugal action, in pressing them outwardly, advances the relative position of the driven disk so as to make foom for the balls

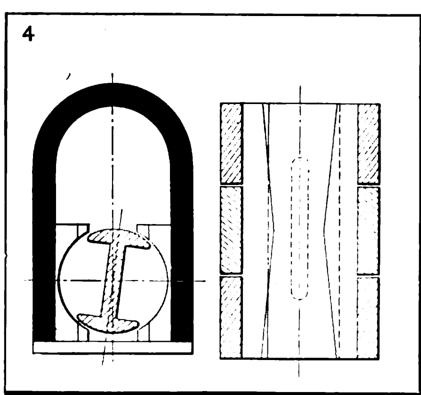

Fig. 4.—Larger ignition angle by re-designed pole pieces

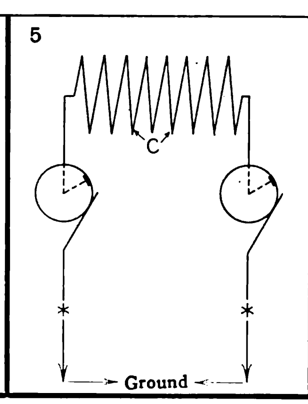

Fig. 5.—Wiring for duplicate spark

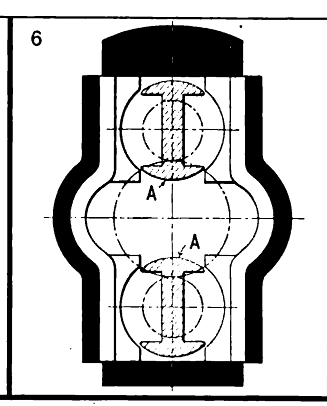

Fig. 6.—Two magnetos on one base

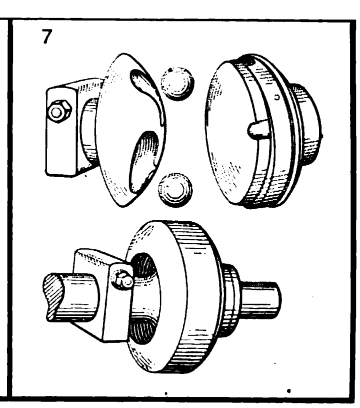

Fig. 7.—Variation of multiple ball coupling

farther out in the grooves. The coupling may be either horizontal or vertical, as in a vertical position of the discs the tendency of the lower balls to take a more circumferential position by reason of their own weight will be counteracted by that of the upper balls to seek the center except perhaps at the start.

A very similar device, but in which one disc is convex and the other hollow, was brought out at the Olympia show in connection with the Simms magneto. This is illustrated in Fig. 7, the upper part showing the coupling in assembly.

Timing by changing the relations between motor and armature shafts has the advantage that the position of the armature giving the highest potential is always utilized, no matter how much the spark is advanced. And this advantage applies also when it is the magnet which is turned with relation to the armature shaft for the same purpose, as in the Mea device whose horizontal bell-shaped magnet is particularly adapted for applying the principle in this form, though it is done by hand from the steering wheel. And in this apparatus the designer has also succeeded in developing the polar masses so that the lines of force produce a maximum in the induced current for such a large arc of the armature circle that an early and a late spark are of almost equal intensity.

Eisemann exhibited magnetos with pole pieces whose contours in the longitudinal extension of the apparatus do not show a straight but a broken line, Fig. 4, and has reached usable angles of displacement up to 150 degrees. The same is said to have been accomplished by Bosch. It is at all events notable that strong sparks are produced at relatively very slow motor speeds at any position of the timing lever, and also that the well-known intermittent resistance of the armature is much less pronounced than in earlier types of magnetos.

Two innovations of more recent origin vie with one another: the two-spark and the twin-spark or dual-ignition devices. The two-spark magneto is applicable especially where it is of importance to effect a rapid combustion of the mixture in a broad combustion chamber, such as T-head cylinders. Unlike the twin-sparker it effects the ignition at exactly the same moment at the two plugs. The principle, as shown in the Bosch and the Mea exhibits, rests on placing the two plugs of a cylinder in series. As the two plugs have only one insulated pole both ends of the induction current are insulated and are led to separate distributors, or to one combination commutator. Fig. 5 shows a diagram of the current distribution. Short-circuiting in one plug from fouling or faulty insulation causes only a stronger spark in the other plug. A switch permits the driver to close one of the circuits and continue working with the other. While a plug failure with this system cannot break down the ignition, a defect in the magneto will on the other hand incapacitate both plugs and with this in view Eisemann and Fein built twin-spark or dual-ignition devices.

Eisemann simply mounts two normal magnetos on one base and drives the two armature shafts, each carrying a spurwheel, from a third spurwheel in mesh with both of them and places the spark-timing device on the shaft of the latter. The Fein construction, on the other hand, represents a combination of two devices in one, Fig. 6. Two armatures A, two commutators and two interrupters form independent sets both served, however, from the same magnetos. The spurwheel whose spindle carries both commutators on opposite sides of the machine, serves to couple the armatures, so that only one more spurwheel is required than in an ordinary single-acting induction machine. An advantage over the Eisemann construction lies in the fact that the base provided for a simple magneto suffices also and as well for the dual device.

The dual devices are useful for other purposes than double ignition. By displacing one of the two armatures 90 degrees there is obtained an ignition apparatus for an eight-cylinder motor and one operating with only one-half the number of revolutions required for an ordinary eight-cylinder magneto. Similarly the construction may be applied to V-motors and fan-spread motors without inadvisable increase of the speed, and the failure of an interrupter in that case puts only one-half of the number of cylinders out of commission. Finally, a combination of single-spark ignition and a direct-current dynamo is possible with this type of apparatus, and the dynamo can be used for charging storage batteries for lighting and other purposes.

Battery ignition is, of course, not contemplated by the manufacturers of magnetos, except for double ignition with utilization of the same plugs and the same high-tension commutators for both ignition methods. By incorporating in the magneto a special wipe-spark device for the battery ignition, the two sparking systems can be rendered independent, in case one of the interrupters should fail.

The coil on the dash, which ordinarily works without vibrator, is in the Bosch construction provided with a vibrator which can be switched in by means of a push button for the purpose of starting the motor from the battery current. Eisemann has for the same purpose a current-breaking ratchet device turned by a small crank.

A starting arrangement enabling the driver to utilize the magneto coil to generate the starting spark was exhibited by Unterberg & Helmle in operation on a car, but the author was unable to examine it closely. Apparently the plan is to accelerate the armature suddenly by means of a lever mounted on the dash, and in addition there is a little steel bottle screwed into the combustion chamber of each cylinder. This is filled with combustible mixture from a compression stroke while the motor is working, and the mixture is released by the same crank lever movement which accelerates the armature, so as to turn the motor over even if no good mixture is otherwise at hand in the cylinders.—From *Der Motorwagen*, October 31.

Market Conditions in Italy

Of the three large Italian automobile factories, the Fiat, the Itala and the Isotta-Fraschini, the two first named send the larger portion of their production abroad, mostly to other Romanic people, and the large number of Renault and English Daimler cars seen in the streets of Milan and other large cities shows that the strong national feeling among the Italians still leaves room for imports from foreign countries in the large and expensive types of cars. The Spa, the Scat, the Lancia and the Nazarro factories, where smaller cars are produced on a limited scale, are not yet in a position to build "in series" and pay duty on many construction parts imported from Germany. It should be possible to import a great many small cars, as such a sales-field as that of the physicians is uncultivated.

There is no dealers' class, in the ordinary sense of the word, in Italy, with very few exceptions. In Milan and Turin the purchaser goes direct to the factory, and a few customers doubtless make trips to these cities for the purpose of purchasing, but ordinarily the Italian will not go to this trouble. He goes to the garage owner and orders a car as he would a suit of clothes from a tailor. The garage man has a number of different makes on hand and catalogs of many others. An importer would probably find it needful to establish salesrooms with stock in Milan and Rome and to build up a sales organization from these centers.

Cabs and specially built public motor vehicles are not numerous in Italy, and the livery work is done mostly with old second-hand private cars, which are expensive to run and inelegant in appearance. And yet the populace of northern Italy loves dearly to ride in a real motor-cab and greatly appreciates elegance in lines and colors of the carriage body.

Italians are perhaps a little less patient about repairs than other nationalities, and stocks of repair parts are a necessity for holding and expanding any trade established in an imported model. They like to do all their dealing with one firm, and an importer will therefore find it of advantage to handle a suitable variety of tires and accessories, possibly in connection with a garage of his own—*Allgemeine Automobil Zeitung*, October 27.

Letters Answered and Discussed

Trouble with Valve Action

Editor THE AUTOMOBILE:

[2,927]—In making repairs on a car having a valve action as represented in Figs. 1 and 2 where F is the fibre insert; S. set screw; B, bushing; and camshaft C I am at loss to account for the excessive amount of noise emanating from this mechanism. The car has run but a few hundred miles, and though the motor was very quiet when new, it is now decidedly noisy. I am sure the seat of trouble is in the valve action, as a cushion inserted between the valve stem and the tappets stills the clatter.

The only wear I have been able to find

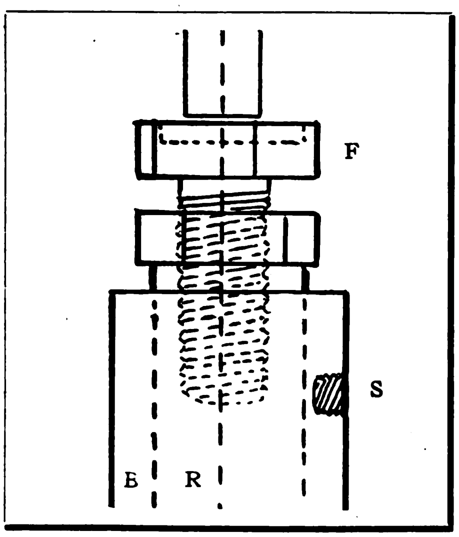

Fig. 1—Upper part of valve pushrod showing manner of adjustment

is as shown in the sketch—on lower end of the pushrod, where it bears on the cam. All of the right pushrods show this wear, which is barely more than 1-16 inch wide.

Would wear in this position, and of this dimension, cause the noise that is present? If so a remedy is obvious in regrinding and again casehardening the end of the push rod R, but as this would be no more permanent than originally I have considered the advisability of substituting a mushroom pushrod without changing the contour of the cams.

I realize this would greatly change the movement of the valve in relation to the position of the piston, causing a quicker opening after leaving the seat and holding the valve in the full open position for a longer interval.

I can see nothing detrimental to the function of parts by incorporating this change and I anticipate a benefit in eliminating much of the side-thrust on the pushrod and obviating wear on the lower end

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

by spreading the wear out over a larger surface. Please tell me if this would be deleterious in the handling of the gases, and if impractical, why.

Does the pushrod bear on the cam during the closing of valve, or does the cam move faster than the spring returns the valve to its seat, when motor is turning above 1,500 R.P.M. SUBSCRIBER.

Northampton, Mass.

The noise you complain of is caused, no doubt, by the wear on the bottom of the pushrods. By screwing upon the adjustment nut located on the tappet rod, the lost motion due to wear will be compensated for, and the noise will cease. It would not be necessary to make the complicated repairs you suggest. The spring action is faster than the camshaft action, hence the pushrod bears on the cam.

Description of Rotary Engine

Editor THE AUTOMOBILE:

[2,928]—The rotary engine recently completed by Mr. Nikola Tesla weighing but 1 pound to the horsepower and being reversible seems to be likely to bring about enormous innovations in automobile practice, so far as motor construction is concerned, so that I hope you will look into the matter and publish such information as you think of interest. CORTLANDT DE P. FIELD.

Peekskill, N. Y.

The description desired may be found on other pages of this issue.

Wants to Know About New Motor

Editor THE AUTOMOBILE:

[2,929]—Do you know anything about the Tesla engine which has been heard of not a little of late? Is there anything in it, or is it only a pipe-dream?

If the engine is an accomplished fact, can you not and will you not give us a full description of it in THE AUTOMOBILE at an early date? Also your ideas as to its possibilities and probabilities of application to the automobile. E. ATWELL.

Mountain Dale, N. Y.

On pages 950 to 951 of this issue a detailed description of the Tesla motor is given. We would call attention to the fact that the data contained in that report are the digest of actual experience.

Avoiding Freezing

Editor THE AUTOMOBILE:

[2,930]—This is the season when antifreezing solutions are in the mind of most operators of automobiles in the North. A great deal can be said for and against many of the preparations now on the market, judging from the literature circulated by the various manufacturing concerns. Will you kindly tell your readers through your answers to inquiries what you consider is the best preparation either on the market in commercial form, or which can be compounded by the autoist himself. The question may have been answered before

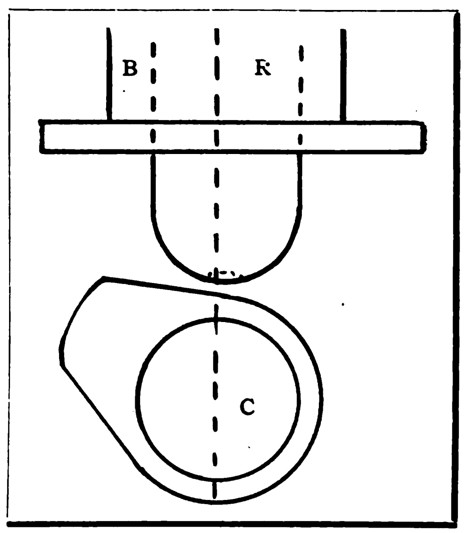

Fig. 2—Lower part of pushrod and cam. Dotted line shows wear on end of rod

but I am sure a repetition will interest a great many others. H. D. MARTIN.

New York City.

The following is recommended by the Thomas company and expresses the ideas generally held at the present date:

A mixture of 25 per cent. of denatured alcohol, which costs the same as wood alcohol but is superior to it for the purposes required, will prevent freezing at almost any temperature we may have here. The drawback to this is the evaporation of the alcohol, and as the boiling point of the alcohol is much lower than water there is a liability of the motor overheating if the weather gets warm.

We have also used a solution of 15 to

20 per cent glycerine with good results, which will prevent freezing to 5 degrees below zero, and has the advantage of not evaporating, but it is open to the objection that on account of the presence of stearic acid in the commercial forms of glycerine it has an injurious effect of decaying rubber hose connections very rapidly, and occasionally bothers the driver by clogging the strainer of the water-pump.

We suggest that the radiator be protected by a leather shield covering one-third of the lower radiator surface, which makes the motor work very much better in cold weather, and also protects the carburetor, keeping the cold blasts of air from passing through the radiator. An excellent protection will be an asbestos board as this is a non-conductor of heat as well as cold. Either the leather or asbestos may be fastened with copper wire.

The method most in vogue with chauffeurs is to throw a robe over the front. Many use chloride of calcium or other solutions where it is necessary to depend upon a dissolving of chemicals, but there is a serious drawback in doing this, owing to the fact that the evaporation of water causes the chemical to precipitate, and in time forms a crust or coating in the water jacket of the cylinders, thereby reducing the cooling efficiency of the cylinders.

If it is ever necessary to have the non-freezing solution which you use during the Winter months drawn out of the radiator, do not forget to personally see that it is replaced, for in many instances we have known of the solution being discarded through an oversight and water put back in its place.

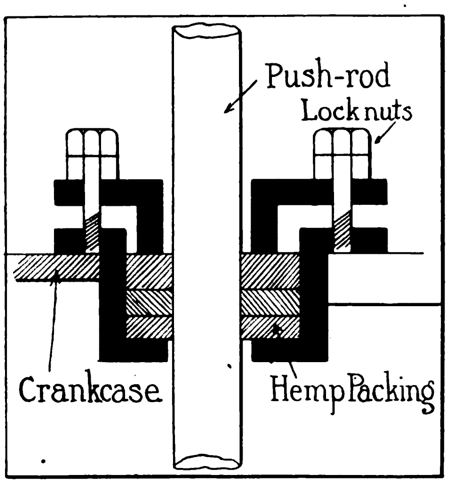

Fig. 3.—Valve rod stuffing box to prevent leakage of oil from crankcase.

Oil Leaks from Crankcase

Editor THE AUTOMOBILE:

[2,931]—Being a subscriber to THE AUTOMOBILE I take the liberty of asking if there is any simple method of preventing the leakage of oil about the valvelifter cages, as these cages become worn a short time after renewing. D. T. DUKE.

Wellsville, N. Y.

The only method which can be used with success is the installation of a stuffing-box. This will have to be done by a regular repairman as it will be necessary to drill and tap the crankcase in order to take any of the standard types. A good form of stuffing-box is shown by Fig. 3.

Truck Statistics

Editor THE AUTOMOBILE:

[2,932]—I wish to ask your opinion as to the probable number of commercial vehicles of all kinds in use at present in the United States. Also, your opinion as to the probable total number of commercial vehicles being produced yearly at the present time. L. B. GAYLOR.

Stamford, Conn.

As near as can be judged, there are over 10,000 motor-trucks operated in this country at the present time. According to the latest available census figures, the increase since 1909 in the number of these vehicles is about 7,000, there being 3,288 in use in that year. It is estimated that in the next 12 months there will be nearly 18,000 commercial cars manufactured.

Rust in Radiators

Editor THE AUTOMOBILE:

[2,933]—When putting my car up for the Winter and letting the water out of the radiator I notice that rust comes out with the water. I have wondered if it would not be all right to put in a quart or more of kerosene or other oil and stop if possible any further rusting. I would let the oil either remain in the radiator or drain it out after a time, or else I could put in a little wood alcohol or other non-freezing solution. I would very much like to have your opinion on this matter. G. W. WILLARD.

Dundee, N. Y.

Probably the best method would be to fill the radiator with a good non-freezing solution, as rust action is very slow when air is not in direct contact with the metal. A 50 per cent. solution of denatured alcohol and water will freeze at 35 degrees below zero and is very safe in most climates. Another good plan would be to run kerosene through the radiator two or three times. This should be done about once a month.

Wants Soldering Information

Editor THE AUTOMOBILE:

[2,934]—I am a constant reader of your publication, but I cannot remember seeing anything in your columns on the art of soldering. There seems to be a dearth of information on this subject and yet it is of great use to a man who takes care of his own car. The greatest trouble with most amateurs I find is the inability to keep the copper in good condition.

I have used sal ammoniac dissolved in water and have also rubbed the copper on a block of the same, but find that it eats the tin away. Is it not possible to get a high grade of copper which will hold the tin on the point without having frequently to re-tin it? Perhaps the quality of the sal ammoniac has something to do with it. I would be very pleased to have any information on the subject available. E. G.

Detroit, Mich.

With copper it would be better to use zinc chloride as a flux. If the copper is heated to redness at any time the tin will volatilize and retinning will be necessary. After dipping the copper into the chloride, the stick of tin is held against the surface and will be found to adhere until it is heated to the temperature of volatilization.

Effect of Alcohol on Carbon

Editor THE AUTOMOBILE:

[2,935]—Would you kindly tell me through the pages of THE AUTOMOBILE what effect denatured alcohol would have on the carbon in the cylinders if injected while the cylinders were hot? GEO. W.

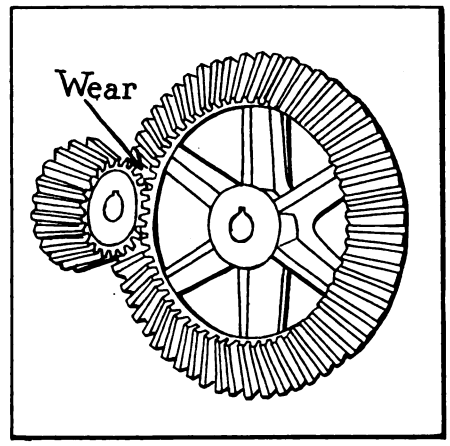

Fig. 4.—Showing the point at which wear and noise occur in the gears

Portland, Me.

It would have absolutely no effect whatever.

Slashing Transmission Gears

Editor THE AUTOMOBILE:

[2,936]—I have a five-passenger touring car of a prominent 1912 make, and find it very nice all around, except that when I change speeds I hear a strange noise in the gearbox. I believe it is lost motion. What can I do to quiet the noisy member?

Rockland, Me. R. H. WATERS.

While it is true, in a way, that all noise is caused by lost motion, the noise experienced by you is not classed in general under that heading. The teeth of one gear strike those of another which it is to engage. Despite the high-grade material used in transmission-gears this practice is very harmful, and in time will spoil a good set of gears. It is either evidence of poor design in a car, or of lack of skill on the part of the driver. Fig. 4 shows the point at which the wear occurs, and it is this wear which causes the noise in the gearbox.

Little Bits of Motor Wisdom

Tools and Other Devices Useful to Repairman and Driver

TROUBLES WITH BOLTS AND NUTS—Care should be taken in starting a nut that it does not get cross-threaded, as shown (exaggerated) at A, Fig. 1. This more often happens when the thread is fine. In any case it often means the replacement of either the nut or bolt, or both, and there is no need for its occurring at all, if the nut is not forced when it is a little bit askew. Often when the nut cannot be made to start on the thread as it should the trouble is due to the burring of the first thread, as at B. This burring usually results from striking the end of the bolt with a hammer. Whenever the use of the latter is necessary, a block of wood should be placed between it and the bolt head. When the end of a bolt is found to be burred in this manner, the trouble can be remedied by using a small file to rethread the damaged portion, first filing off the burr. Perhaps one of the worst mishaps is to twist off a bolt at some important point. This often results from trying to force the nut beyond the end of the thread when it is already against the shoulder, as at C. Sometimes the nut will split instead, if it is the weaker number, this being, of course, the lesser of the two evils. To prevent either from happening, place a washer or two over the bolt before putting on the nut, as shown at D. This is merely another ounce of prevention. When the thread is found to be poorly made in some such manner as is shown at E, the best thing to do is to run a thread-cutting die of the proper size, that is, having the same number of threads per inch as the bolt has, over the imperfect thread in order to reduce it in diameter near the shoulder. If the nut fits the smaller end, it will jam when screwed up farther, and will eventually either split or twist off. When the nut to be adjusted is rather inaccessible, there is no tool in the kit more handy than the socket-wrench, although some drivers do not include one in their equipment at all. Once they have to get at some hidden part at the lower end of the steering column, or at some other equally inaccessible point they will soon appreciate the need of such a tool.

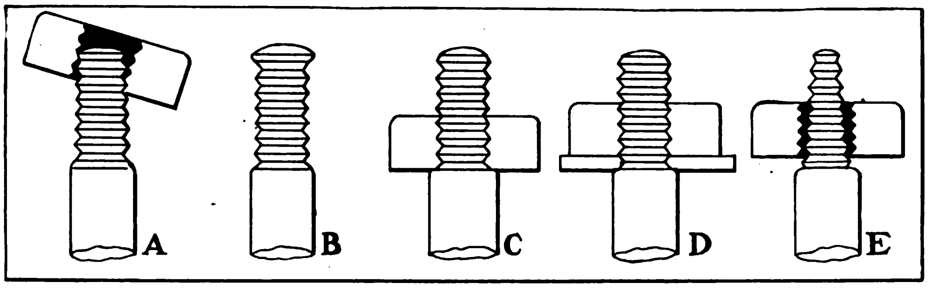

Fig. 1.—Illustrating the different ways in which threads are abused; also, defective thread

RUST IS AN ENEMY OF TIRES.—Rust eats into rubber tires like lye. It is usually formed on the rims and then gets onto the envelopes of the tires near the beads. In time this rust will eat through the rubber and attack the canvas as well. It is best to remove the tires from the rims when this discoloration is noticed. Get the rust off the tires first, then take some heavy emery cloth and clean off the rim with it as well as possible. Next use some finer emery cloth and rub the rim until it is thoroughly free from the deposit and is smooth. If the rim is quite rough and uneven, first take a file and smooth it down before applying the coarse emery paper. After making the rim perfectly smooth rejapan it with one or two coats, and after this dries, rub it down again with the emery paper. This should entirely eliminate the rust, and make a smooth rim for the bead to fasten on, thus also doing away with the danger of tearing the latter every time the tire is removed. Another preventive of rust is flake graphite. To apply this to the rims, put on them a coat of shellac to which has been added enough graphite to form a thin paste. Graphite may also be used in the place of chalk or soapstone between the inner tube and the shoe. It is less injurious to the rubber, is more lasting, makes a good fit of the inner tube and reduces the heating. This, of course, refers to flake graphite.

THE ALLIGATOR WRENCH—It is often said that there is nothing new under the sun and this can certainly apply very readily to the tool known as the alligator-wrench. This useful article, while not exactly new, fills such a variety of purposes that it is worthy of more than a mere passing notice. The alligator-wrench which is illustrated in Fig. 2 consists of two fixed jaws which are serrated in the form of teeth and from which the wrench takes its name. It is more or less of a rough-and-ready tool inasmuch as when it becomes necessary to hit the work a few gentle taps it can readily be done with this wrench without grave danger that the tool will be greatly injured, as is the case with the more delicate monkey-wrench.

Many a good and useful wrench has been ruined through its misguided use as a hammer or mallet, and yet there are cases where it is not convenient to drop everything and secure a hammer when it seems that a couple of blows with the back of the wrench would readily do the work without further trouble. The alligator-wrench will fit any hexagonal nut sufficiently well to turn it to a reasonable degree of tightness. However, it must be remembered that this tool can be abused just the same as any other.

The chief objection to the alligator-wrench is that it is very apt to claw the corners off the nuts if it is used excessively. This is particularly true if great stress is put upon it, as in the case of tightening the nut, beyond the point where it will turn readily. That this should be true is readily apparent as it is a parallel case to using a wrench which is not an exact fit. In this case, if sufficient pressure is applied against the resistance to turning of the nut the corners will be stripped so that the hexagonal nut tends to take a round shape.

There are numerous instances where a wrench cannot be carried for every different-sized nut, and in this case the alligator-wrench is indispensable, for, owing to the long range in sizes of nuts which can be readily manipulated, provided they are not required to be tightened to too great an extent, there will rarely be a case which cannot be met with this form of wrench. In case the nut which has to be removed is rather tight, it is a very simple affair to strike it a few slanting blows with the wrench which will generally serve to

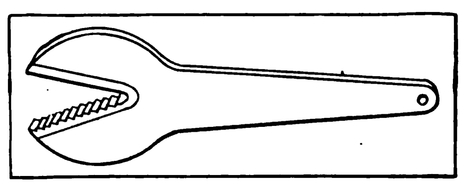

Fig. 2.—Showing an alligator-wrench which is often of use

loosen it to such an extent that the wrench may be applied for the complete removal of the fitting.

In case the nut which is to be removed will not loosen readily a method which is often successful is to apply the flame from a gasoline torch to the nut and then to gently tap the nut on one of the corners, being careful to apply the torch so that the flame is just on the nut. If no torch is available a little waste dipped in gasoline, wound about the nut and then lighted will do the work.

Oil Cans to Be Carried—The railroad engine driver with his rack of oil cans does not find a parallel in the driver of the modern automobile, so far as these instruments of lubrication are concerned, because the problem of accessibility is not only much more simple in the automobile but also because the problem has of late been given the attention it deserves and inaccessible spots are rapidly vanishing. The spectacle afforded in past years, of seeing the operator of a gaily painted automobile lying flat on his back in the middle of the road vainly tinkering with the mysterious and hidden secrets of the mechanism has all but vanished until in these days the search for trouble has resolved itself, for the most part, into a simple lifting of the bonnet.

It is the same thing in the way of reaching parts to be oiled. The oiling spots on the automobile are well defined and the schedule of oiling has been reduced to a basis of hours and quarts or in other cases to miles and quarts. The motor is always mechanically lubricated and once the oil is in the reservoir the operator need not bother about it until the level gauge indicates to him that the supply is running short and should be replenished. A small oil can will be of use to the automobile driver; in fact, two of them should be carried, with different-shaped nozzles, one for oil and the other for gasoline, as shown in Fig. 3. The gasoline should be carried in the can with the straight nozzle and the oil in the can with the curved nozzle. The gasoline will be found to be of a variety of uses such as priming the motor and cleaning the hands after working about the engine.

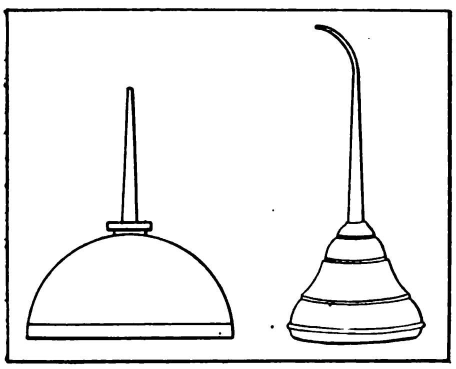

Fig. 3—Two oil cans may be carried for gasoline and oil

It will often be found advisable to put a drop or two of oil at different points, and the oil can will be found to be of the greatest convenience. There are several points which are beyond the classification of regular lubricating points, such as the compression cock handles, magneto and water pump bearings, etc. These require a few drops occasionally where they are not provided with grease cups. A grease gun is often of use in putting the lubricant in its proper place.

Using the Spanner Wrench—One of the most important tools in the kit is the spanner-wrench, yet it is capable of much damage to nuts and bolt-heads when improperly used. The number of cars to be seen in which there is tell-tale evidence that the owner or driver does not yet know how to properly manipulate the tool is surprising. This may be due as much to carelessness as to neglect, but nevertheless the burred nuts speak for themselves. Of course, these remarks apply principally to the adjustable spanner, the ordinary standard spanners not admitting of serious misuse, since they can be used only on the size nuts for which they were made. In using the spanner it is essential to get as firm a grip as possible on the sides of the nut. If improperly adjusted as shown at 1, Fig. 4, the corners of the nut are sure to be worn away, or badly burred, and, if the practice is continued, the nut soon becomes useless until new faces are made on it. This is true particularly of brass or bronze nuts, or others made of soft material. Another misuse is that of not putting the wrench far enough on the nut, as shown at 2. While this also tends to burr the corners of the nut, it spreads the jaws of the wrench and strains them so that when next applied to a nut, they will not fit accurately, as shown at 3. At 4, in Fig. 1, is shown the proper way to use the tool, the jaws being given as much bearing surface as possible on the faces of the nut. When adjusted in this way there is little danger of rendering impossible the removal of the nut after about the third time. Never apply too much force when tightening up a nut. It is possible to strip the thread, or, worse yet, to turn the end of the bolt off by using a heavy, long-handled wrench on a small nut. Few realize the enormous force which can be exerted by a long-handled wrench, even when the force applied is not very great. Another mistake is to use pliers for the adjusting of small nuts, such as those on the magneto or carbureter. A small spanner is far better for the purpose and should be used wherever possible. The ease with which these small nuts are burred makes it necessary to be very careful when applying even a spanner to them.

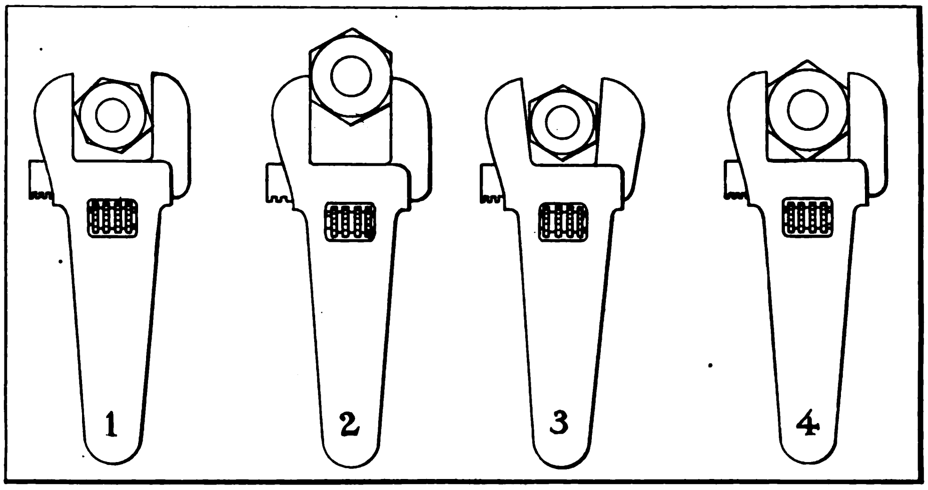

Fig. 4—Showing the use and misuse of an adjustable spanner-wrench

Clean Differential Housings—It is occasionally necessary to remove the cover from the differential housing and give the contents of this casing a thorough cleaning and overhauling. If long life is desired in all parts of the motor, cleanliness will be the great means of securing it. In cleaning the differential housing the cover is removed and the casing flushed out with kerosene. The motor is then allowed to run for a few seconds and the casing again flushed out, after which it is refilled with the particular oil or grease recommended by the manufacturer. The casing is then screwed into place. There is generally a cock in the bottom of the differential housing through which the kerosene is drained before the housing is refilled.

In replacing the cover after putting in the grease, care should be taken in tightening up the screws that hold the cover in order not to turn off a head. When this happens, it is rather hard to get at this part of the car to remove the portion of the screw remaining in the tapped hole.

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

A Gasoline Gauge

Editor THE AUTOMOBILE:

I read with interest the suggestions for repairs and of the improvements which others have made on their machines, and I am sending you a sketch showing a gasoline gauge which I have fitted to my tank, the latter being under the front seat. This has proven very satisfactory, and is inexpensive. If you deem it worth publishing, it may interest someone else. Fig. 1 shows the gauge D attached to tank A. Two 1-4-inch unions C are used, and the stop-cock B is included so that the gasoline may be shut off in case the glass breaks. A detail of the gauge proper is shown to the right. The brass caps E are tapped for a 3/16-inch brass rod F, which secures the 5-8-inch steam boiler gauge glass G. The pipe connections to the tank are shown at H. Leather washers should be placed at K to prevent leakage.

ELMER C. NORTH.

Juniata, Pa.

When the Gasoline Gives Out

Editor THE AUTOMOBILE:

"The gasoline tank is empty." What a hollow sound these words have if one is stranded a few score miles from home! But don't give up the ship. Just disconnect the tubing which supplies the acetylene gas to the headlights and insert it in the primary air intake of the carbureter, as shown in Fig. 2. Turn on the gas and adjust it so that the motor will run well at a moderate speed, and proceed on your homeward way. Of course, the speed of the engine cannot be controlled very well, because the supply of gas remains constant and does not vary with the suction as does the liquid gasoline. However, by proper manipulation of the spark lever, one may "get there."

MURRY FAHNESTOCK.

Allegheny, Pa.

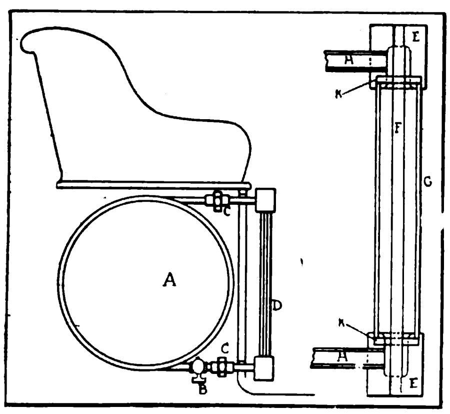

Fig. 1.—Suggested form of gasoline gauge

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyse your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

That Tire Pump

Editor THE AUTOMOBILE:

Mr. Ed. C. Bates, in the October 26th issue, described a method of making a tire pump. I made one according to directions, I believe, but could not get any air into my tires. I have a two-cylinder motor, which perhaps runs too fast, and I cannot throttle it down as far as a four-cylinder motor. I would be greatly pleased to make this pump and would like to have further directions.

Atkinson, Ill. THEO MILLER.

—

Editor THE AUTOMOBILE:

In your issue of October 26 there appeared an article which gave directions for making a tire pump and asking the opinions of readers on the contrivance. I would say that I have followed these instructions, using the pump on a four-cylinder engine with a bore and stroke of 4¼ inches by 4¼ inches, and the same will absolutely not work. It is only a waste of time and material to experiment with such a contrivance on an engine of this size.

Albany, N. Y. H. M.

—

Editor THE AUTOMOBILE:

In the October 26th issue of THE AUTOMOBILE on page 728 is a sketch and description of a home-made tire pump, operated by screwing it into the engine cylinder in place of the spark-plug. I would like to know if such a pump would operate properly in connection with an L-head or a T-head motor. Would pure air or a mixture of gas and air be delivered to the tire, and, if any gas, approximately how much and what would its effects on the tire be? In addition to your direct answer, I would like to see replies from some users of such a device, either home-made or such types as are regularly for sale.

Pittsfield, N. H. WILLIAM B. ELY.

—

Has any reader constructed this pump and made it work satisfactorily? The suggestion and sketch were submitted by Mr. E. C. Bates, of Clarksville, Tenn., and while THE AUTOMOBILE has not actually constructed the apparatus, the idea appears to be reasonable, although perhaps rather impractical. If it will work at all, there is no reason why it will not operate equally well on either a T-head or an L-head type of cylinder, since it depends for its operation on the compressive force and not on the cylinder design. A mixture of gas and air would be delivered to the tire, but the amount of air in proportion to the amount of gas would no doubt be great enough to counterbalance any ill effects which the gas might possibly have. Perhaps Mr. Bates can explain why these correspondents have not been successful with his contrivance, and can give more light as to its construction and manner of operating.—EDITOR.

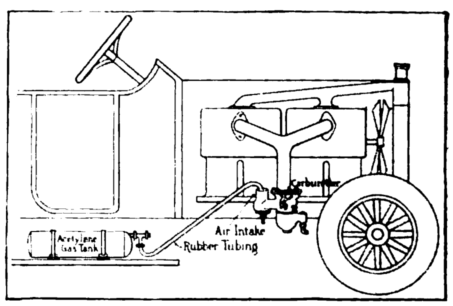

Fig. 2.—Emergency use of acetylene gas to run motor when gasoline supply is exhausted

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Perhaps You Are Right

Editor THE AUTOMOBILE:

In THE AUTOMOBILE for October 26 Mr. P. G. Tismer gives his idea of what a low-priced car should be. His is certainly a most desirable car. I would suggest, however, that besides doing away with the carbureter the engine should also be omitted, for even a single-cylinder engine is more or less complicated and I think that Mr. Tismer's car would run just as well without the engine. I am sure that it would coast better without this complication and the control would be greatly simplified, for even the spark advance and transmission could be done away with. I am glad to see that "mud guards and top are put in position when needed." I presume that these useful accessories are folded up somewhere in the body of the car and, if the driver should be unfortunate enough to encounter a rainstorm while out on the road, he would only need to pull them out, adjust them and bolt them on his car—a simpler operation, surely, than raising an umbrella.

BARRY MACNUTT.

South Bethlehem, Pa.

From a Racing Driver

Editor THE AUTOMOBILE:

I have been asked to state my ideas of what would be considered a first-class fool-proof automobile for the general public to own. By general public, I mean the people who own and run their own machines, and who have little or no knowledge of what is under the hood and footboards.

To start with, I would have a reinforced, pressed-steel frame. I have seen so many frames on good cars that would sag in the center or crack near the dashboard that I believe they should be reinforced in these places. The springs should be elliptic and should be of ample size to withstand the jar of the machine over rough roads without fear of breakage. I also believe there should be straps on the springs to eliminate the rebound, as it is not the contraction of the springs that breaks them, but the rebound.

The engine should have a bore of about 4 1-4 inches or 4 3-4 inches and a stroke of either 5 inches or 5 1-2 inches. The valves should be large, and the connecting-rods should be strong enough to withstand the power of the explosions. A good splash-feed oiling system that could be relied upon to do its duty at all times should be used.

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic, to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

The engine should be strong and simple, and built so as to be easily accessible in case of emergency.

I would use a Remy magneto, which is simple and easy to adjust, also a model L Schebler carbureter, which is about as fool-proof as any carbureter made. The latter may use 5 cents' worth of gasoline more a month than some others, but it will always get you home.

A cone clutch with spring inserts gives one as much satisfaction as any other kind. It never runs dry of oil, and, with a little care, will give good satisfaction. A three-speed selective-type transmission made of good materials and of sufficient strength will prove satisfactory.

A full-floating, ball-bearing rear axle fitted with internal and external brakes would be desirable, and I would have 34-inch by 4-inch wheels. The B. & L. caster front axle would put the car under absolute control of the driver, would eliminate a great many accidents and would also leave the driver's arms and shoulders in a better condition at the end of the day's run. This axle makes the car 90 per cent. easier to control. I am a racing driver, and I believe that before long all the leading factories having racing teams will equip their cars with the B. & L. front axle, in order to insure their drivers' safety. Otherwise, there are so many drivers being killed that there will soon be a scarcity. Factories will have to insure their drivers' lives by putting this axle on their cars.

HARRY BUCKLEY.

Cars Good Enough as They Are

Editor THE AUTOMOBILE:

To my mind, several of the cars which are being shown for next year come as near to the ideal as we are apt to get with the knowledge which the automobile engineering fraternity has at its command at the present time. Some readers' opinions are so radically different from the actual models as produced by engineers who have had many times their experience, that they are freaks even on paper. The automobile of to-day has passed beyond the freak and experimental stage, and the better makes are as near to mechanical perfection as can be desired. Besides being correctly built mechanically, they are built so as to be a comfort and pleasure to the motorist. Accessories are placed in a particular place only after careful consideration as to their accessibility. Springs and shock absorbers have at last been constructed in such a way as to make easy riding the rule rather than the exception. Self-starting and electric lighting make it unnecessary for the driver to leave the car to light the lamps or to start the motor. In a word, the noisy makeshift cars of the past have been superseded by the silent, smooth-running machines of the present. No longer is the monster's approach heralded for several miles before it actually appears. The days of such nuisances are past and now we have gasoline cars which are equal to electrics without the latter's disadvantages of limited mileage and small capacity.

Therefore, why suggest radical changes, when if the wise manufacturers had deemed them necessary they would have long since been incorporated in the existing models?

The long-stroke motor has advantages which cannot be overlooked, so in my car I would specify this feature. I would require ample power so that I would not have to take the other fellow's dust or have to resort to the low gear to take me over steep hills. The motor would have six cylinders, as for smooth riding and easy running and for flexibility there is nothing, in my opinion, equal to the six. Flexibility cannot be too highly praised especially where the car is to be used in heavy city traffic. Any of the high-grade power plants would be acceptable, preferably one which had three-point suspension. The carbureter should have two jets, and there should be an auxiliary air valve, which could be adjusted from the seat.

I would want the latest type of body construction, with the control levers in the center of the car. With the prevailing types of fore-door models, there is scarcely room on the right side for these levers. This also admits of access to the driver's seat from the right side of the car.

Such a car as I have outlined could not be bought for a song, but would possibly cost anywhere from $3,500 to $5,000, although there are several worthy machines for 1912 at a much lower figure.

Automobile Metallurgy Made Easy

By E. F. Lake

Part II.
The Elastic Limit

Value of This Factor in Different Materials Entering Into the Automobile Make-Up—How Obtained and Why It Is Necessary

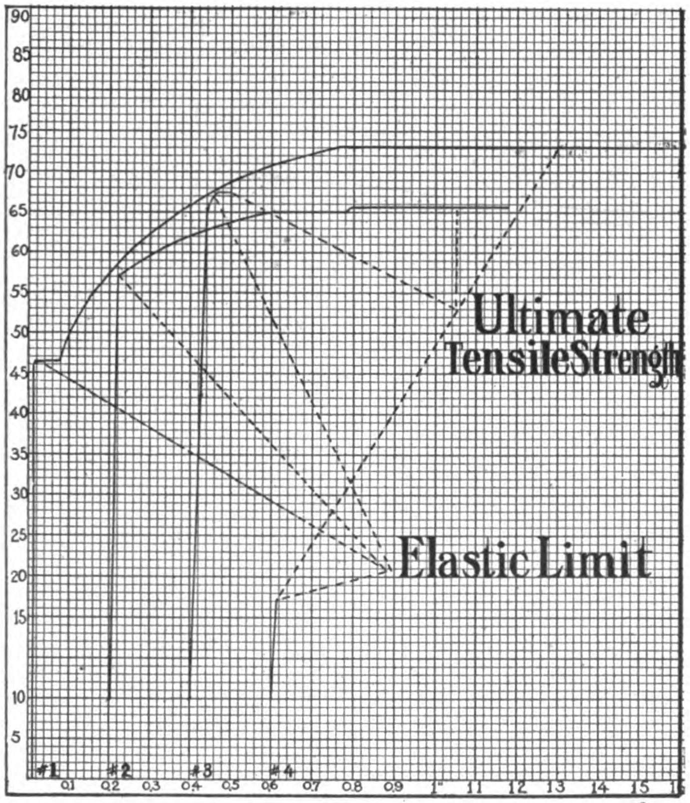

Fig. 1.—Chart showing tensile strength, elastic limit and elongation. No. 1, machinery steel; No. 2, cold-rolled steel; No. 3, brass; No. 4, cast iron.

AFTER the tensile strength has been considered, the most important factor in the strength of metals is the elastic limit. In pulling test bars apart in the tensile testing machines, shown in Part I, they will stretch a certain distance and then spring back to their original length. When stretched a little further, however, a permanent set takes place and from this they will not spring back. The point between these two is called the elastic limit, *i. e.,* the limit of the elasticity of the metal.

The difference between the pounds pull required to make the metal first take this permanent set and that required to reach the ultimate tensile strength and break the specimen varies considerably with different metals. In pulling test bars apart a gradual rise in the number of pounds is shown by the scale beam from the time the pull is started until the elastic limit is reached. When the permanent set first takes place the scale beam halts, in its upward motion, for a fraction of a second and then shows a more gradual rise from this point until the limit of the tensile strength is reached and a break occurs. This is due to the metals stretching much more when the elastic limit is passed than they do before it has been reached.

With most tensile machines, such as are shown in Part I, on tensile strength, a chart is provided and on this is lined, with a stylographic pen, the action of the scale beam. A reproduction of such a chart is shown in Fig. 1. In this chart line 1 shows the results obtained with a machinery steel test bar; line 2 those obtained from a test bar of cold-rolled steel; line 3 is that traced from a brass test bar, and line 4 is the verdict acquired by pulling apart a cast-iron test bar. As will be seen, cast iron is brittle, has almost no elasticity and hence breaks at the elastic limit; brass has very little elasticity and breaks slightly above the elastic limit; cold-rolled steel shows some 8,000 pounds difference between the elastic limit and the ultimate tensile strength and machinery steel shows 26,500 pounds difference.

Many have argued that after the elastic limit of a metal has been passed its usefulness is destroyed. They base their argument on the statement that a given material might stretch for a long distance before breaking. They cite putty and other plastic materials as examples of this. Such arguments come, however, from a consideration of only a part of the problem strength of materials or from those who only know half of the truth.

As an example of this, steel wires, rods and cables that perform a work such as those do in the Brooklyn bridge might be loaded to 46,500 pounds per square inch and take a permanent set or reach their elastic limit if made from the machinery steel shown in the chart, Fig. 1. Their usefulness would not then be destroyed, as it would take 26,500 pounds per square inch more, or a total of 73,000 pounds, before a break would occur.

The frame of an automobile might be compared to the materials in a bridge, as it performs a similar work. The elastic limit of this may be considerably exceeded without causing it to break, and the breakage of the frame is the real important factor. Many an automobile has had its frame twisted and bent out of shape. This frame has been straightened and the car made to do its daily work thereafter. In these twists and bends the elastic limit has been exceeded but the ultimate strength has not been reached, hence the cars are as good for practical use as they were before. Even gear teeth, after they have been worn considerably, might be strained until the elastic limit was exceeded and thus be permanently bent. After that they might do a lot of work owing to their not having been strained until the ultimate tensile strength had been reached and the teeth thus broken.

A few cases of this nature, however, do not prove that the elastic limit of metals is not of vital importance. Most parts of a car should retain their original size and shape, if the car is to work properly and have a long life. If the elastic limit of many of the working parts is exceeded, their size is altered and they will not fit properly. This would cause them to interfere with other parts and hence clog them or seriously hinder their movements. In such places the elastic limit of the metals cannot be exceeded, and these are usually the parts that require the very strongest of materials. It is, therefore, the aim of many automobile designers to obtain materials in which the elastic limit can be raised up close to the ultimate strength and thus enhance their usefulness.

The elastic limit, as well as the tensile strength, can be greatly increased by a proper manner of heat-treatment, *i. e.,* hardening and tempering. Many of the special alloy steels have been adopted for various important car parts, as with these the tensile strength can be raised to a high figure and the elastic limit brought up closer to it than can be done with the ordinary carbon steels. Nickel, nickel-chrome, vanadium and titanium steels can all be worked and heat-treated so as to bring the elastic limit up close to the tensile strength. This is well illustrated by the table herewith. Raising the elastic limit close to the tensile strength also greatly enhances the resistance of steel to tortional and impact strains, and to rotary and alternating vibrational stresses. Many parts of an automobile are subject to extreme strains and stresses of these natures.

All steels are much lower in tensile strength and elastic limit when in an annealed or normal condition than when correctly heat-treated. As they are shipped from the steel mill in this annealed condition they must be properly heat-treated in the automobile factory before they are put on the car. The difference of strength between annealed and heat-treated steels of various kinds is also well shown in the table. All of these cases show the importance of knowing the elastic limit as well as the tensile strength of the various metals used in a motor car.

Careful car builders pull apart sample test bars from each lot and kind of metal ordered and do not leave this to chance. The elastic limit is then always given with the tensile strength. It is, therefore, not difficult for the buyer, user or seller to obtain the information that is necessary for a thorough knowledge of the car's mechanism.

TABLE SHOWING THE EFFECT OF HEAT TREATMENT ON THE TENSILE STRENGTH AND ELASTIC LIMIT.

Kind of Steel.	ANNEALED STEEL.		HARDENED STEEL.	
	Pounds per Square Inch of			
	Tensile Strength.	Elastic Limit.	Tensile Strength.	Elastic Limit.
Very low carbon	61,500	35,200	73,100	39,600
Low carbon	66,500	41,200	99,400	54,000
Medium carbon	97,800	52,600	132,100	81,400
High carbon	116,400	66,500	153,400	102,100
Very high carbon	130,700	75,800	180,100	105,500
Nickel	88,000	60,000	225,000	224,500
Nickel	87,640	64,400	125,000	103,000
			127,800	110,100
		Drawn at Various Temperatures	130,500	124,000
			138,000	127,500
			147,000	140,750
			212,000	200,000
			232,750	224,000
Chrome nickel (soft)	114,000	93,000	206,000	185,000
Chrome nickel (hard)	135,000	107,000	285,000	270,000

Removing Odor from Rubber Articles

Rubber mats in the interior of closed automobiles are frequently objectionable by their odor. This can be removed, however, by subjecting them to the same process which is employed in the case of small articles of vulcanized rubber, such as tobacco-pouches and dress-shields, which are carried on the person. The articles to be deodorized are placed in a metal box between layers of finely pulverized carbonized bone, and the box is then left for four to eight hours, according to the size of the articles, in a place, such as a drying room, where a temperature of 60 to 70 degrees Centigrade can be maintained. If the bonemeal is to be used again for the same purpose, it must first be brought to red heat in a closed metallic vessel, in the cover of which there must be a vent, and it must be left to cool therein. The deodorized rubber articles must not be placed together with other rubber articles which have not been so treated, as they will acquire their old odor again, in that case, with surprising rapidity. Unburned magnesia powder can also be used for removing the odor. Merely sprinkling it over the article will have some effect.—From *Gummi Zeitung*, August.

Calendar of Coming Events

Shows

Dec. 30-Jan. 6......Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.
Jan. 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 13-27.........Philadelphia, Annual Show, First and Third Regiment Armories, Philadelphia Automobile Trade Association.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 13-19.........Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 22-27.........Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dealers' Association.
Jan. 22-27.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 27-Feb. 10....Pittsburgh, Pa., Sixth Annual Show, Automobile Dealers' Association of Pittsburgh, Inc. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 29-Feb. 3......Scranton, Pa., 13th Regiment Armory, Second Annual Show.
Feb. 1-7...........Washington, D. C., Annual Show, Convention Hall.
Feb. 3-10..........Montreal, Canada, National Show, Drill Hall, Automobile Club of Canada.
Feb. 5-17..........St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17.........Ottawa, Ont., Howick Hall, Annual Show, Ottawa Valley Motor Car Association.
Feb. 12-17.........Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24.........Pittsburgh, Pa., Second Annual Show, Exposition Bldg., Pittsburgh Auto Show Association, Inc.
Feb. 17-24.........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Feb. 19-24.........Omaha, Neb., Seventh Annual Show, Auditorium, Omaha Automobile Show Association.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 20-24.........Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Feb. 20-28.........Baltimore, Md., Annual Show, Baltimore Automobile Dealers' Association.
Feb. 21-28.........Toronto, Ont., Annual Show, Toronto Automobile Trade Association.
Week Feb. 22......Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
Feb. 24-March 2...Brooklyn, N. Y., Twenty-third Regiment Armory, Annual Show, Brooklyn Motor Vehicle Dealers' Association.
Feb. 26-Mar. 2.....Elmira, N. Y., Second Annual Show, Elmira Automobile Club.
Feb. 26-Mar. 2.....Paterson, N. J., Annual Show, Fifth Regt. Armory, Paterson Automobile Trade Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.
March 4-9.........Denver, Col., Auditorium, Annual Show.

Growth of Automobiles

FEW statements show better the growth of automobile traffic in the country than those made by Colonel William D. Sohier, high commissioner of the State of Massachusetts, at the recent good roads convention at Richmond. In order to get an accurate estimate of the kinds of traffic on the roads of the state 240 stations for counting traffic were selected along these highways. For 14 hours each day and for 7 days in August and 7 days in October this count was carried on. By this actual method of counting it was discovered that on some of the leading state roads 90 per cent. of the traffic was of the motor car variety and that as many as 1,190 cars passed a given point in a single day. Roughly, the fact showed that on some of the roads adjacent to Boston, where mixed traffic was expected, over 60 per cent. of the vehicles were motor-driven. When the average for all of the stations throughout the entire state was taken it was discovered that on the 7 days in August 42 per cent. was motor traffic and in October 35 per cent. motor and 65 per cent. horse traffic. Before these figures were announced it was commonly stated that horse traffic was nearly five times as great as motor traffic, a claim doubtless due to the fact that horse traffic moves slowly and that a horse vehicle may be seen many times on the highway before it has vanished from sight, whereas the motor vehicle is generally seen but once and that for a very short time before it vanishes from sight. This count has demonstrated to the people of Massachusetts that the motor vehicle will in perhaps another year have dislodged the horse vehicle from the position of premiership it has occupied.

The big lesson in the above figures is the application of this truth to the good roads problem. Up to the present the farmer and many legislators have urged that owing to the motor vehicle constituting a small percentage of the total traffic it should not receive as much consideration in the road building business as the horse-drawn vehicle. This count establishes beyond the shadow of a doubt that when road building is under consideration in that state those kinds of roads best suited to the motor car should be first considered. The days were when in building a road the question was to build a road for horse traffic; to-day this is changed and the problem is to build a road suited for motor vehicle traffic. The last few years have proven that roads suited for horse traffic are not suited for motor traffic. The macadam which is successful for horse traffic is an utter failure for motor traffic and states that are building macadam roads to-day and expecting them to endure will be disappointed in less than a year. The road for the motor vehicle requires a good binder, a substance that will hold the road material together, a substance that prevents disintegration due to too much moisture and a substance that will bind the road surface together in dry weather and so prevent dust. Many state road commissioners have known for years the kind of road best suited for motor traffic, but owing to the imagined preponderance of horse traffic they have not dared to build the motor road. Massachusetts deserves credit in setting an example to other states. It is questionable if in any other state the percentage of motor vehicle traffic is so heavy, but the truth is always strong and it would be well for others to get the exact status of the road traffic.

One of the factors much in favor of motor traffic is the low percentage of accidents with automobiles as compared with horse-drawn vehicles. Roughly speaking the accidents with trolley cars per mile traveled is eight times that of motor vehicles. From newspaper accounts it would seem that with the automobile the number was many times greater per traveled mile than with the trolley. The trolley with its own right of way and its confined road of travel should not meet with so many accidents as the newly arrived motor car. These facts speak well for the control of automobiles as well as for the caliber of the people operating them.

So great has the motor industry become in the older states that the old-time antipathy is not encountered and in the new states of the West so many of the farmers are buying cars and this new method of transportation is so popular that the antipathy that is sometimes shown in the East will never exist there. It is fortunate that the good roads movement is rising with the waning of the antipathy, because it brings farmers and car owners together in the work that is so much needed. It is questionable if there is any other force of greater influence in winning interest in good roads than the fact that the car has been taken up in the small towns and cities where the farmer gets closer to the machine owner than he does in the big cities. Once the farmer owns a car, be it ever so small, or rides in one, he becomes a convert to the good roads cause and as soon as one farmer is won over the others soon follow. The modern automobile is a great educator and the road improvement made during the last year in such states as Iowa and Georgia, to which might be added Nebraska and Colorado, is largely due to the education worked and inspiration stimulated by the car. To-day delegates are going to the good roads conventions in their motor cars instead of in the trains. Some delegates tried to reach the Richmond convention of last week in their cars but failed because of the deplorable condition of the roads. Their failure has but created a stronger conviction for the necessity of good roads. The automobile has been largely responsible for this situation.

News of Shows, National and Local

WITH seventy manufacturers of commercial vehicles and 138 parts and accessory makers signed up to show at Chicago, truck week prospects for the annual automobile show present brilliant possibilities. It has been estimated that the use of commercial vehicles in Chicago territory has increased 35 per cent. during the past year, and the business element of the territory is much more intensely interested in automobile trucks than it was formerly. Consequently, a larger patronage of the coming show is looked for than ever before.

The poster which will be used to advertise the Madison Square Garden show of the Automobile Board of Trade has made its appearance. The subject is an Oriental girl bedecked with Eastern jewels and wings. She stands with arms outstretched, holding a passenger automobile in one hand and a business wagon in the other.

Only progress was reported on the plans of the new show building which will be erected north of the present Grand Central Palace. After they are completed it will be necessary to lay them before the New York Central for approval and pending such approval the authorities decline to give out anything official.

Plans for Washington Exhibition

WASHINGTON, D. C., Nov. 27—Plans are under way for the annual motor car show under the auspices of the dealers of this city. A meeting was held this week, which was attended by thirty-three dealers, representing eighty-five different makes of cars, and the following show committee was elected: W. C. Long, chairman; John R. Thomas, secretary; J. M. Stoddard, treasurer; Claude Miller, T. S. Johnston, Taylor Pollock, E. C. Bull, and S. A. Luttrell. February 1-7 were the tentative dates agreed upon.

There is also some question whether Convention Hall, which is the only available place in which to hold a show, can be obtained on that date. It was decided to confine the show to pleasure cars, eliminating accessories and motor trucks. This decision caused a slight row among those who were thus barred from the show, but as the pleasure car dealers were in large majority and as there was every assurance that every inch of space would be taken by them, the decision was allowed to stand. Drawing for space will take place within the next two or three weeks.

Detroit Dealers' Show January 22-27

DETROIT, MICH., Nov. 27—Practically every Detroit manufacturer of motor cars and no less than 35 dealers, handling all the best-known cars manufactured in this country, will be represented at the 1912 show of the Detroit Automobile Dealers' Association, to be held in the Wayne pavilion, January 22 to 27.

Those who have already secured space are: The Regal Motor Car Co., the Elmore Automobile Co., the Chalmers Motor Co., Cartercar Co., Cadillac Motor Car Co., Olds Motor works, Standard Automobile Co., representing the Packard Motor Car Co.; Winton Motor Car Co., Brush-Detroit Motor Co., Neumann-Lane Co., agents for the Pierce, Stoddard-Dayton and Rauch-Lang cars; the Buick Motor Co., Lozier Motor Co., Cunningham Auto Co., agent for the E-M-F and Flanders cars; the Ford Motor Co., Abbott-Detroit Motor Co., Lion Motor Sales Co., Seidler Motor Sales Co., agents for the Jackson car; Warren Motor Car Co., Gant Bros. Auto Co., agent for the Everitt and Amplex cars; United Motors Detroit Co., representing the Maxwell cars and the Sampson truck; Thompson Auto Co., agent for the King car and the Van Dyke and Mack trucks; the General Motors Co., showing the Reliance and Rapid, Buick and other commercial vehicles; J. P. Schneider Co., representing the Stevens-Duryea car; Detroit Hupmobile Co. and the Gillespie Auto Sales Co.

The following independents have applied for space: Anderson Electric Car Co., maker of the Detroit Electric; the Motor Wagon Co., Oakland Motor Sales Co., the Paige-Detroit Motor Car Co., the Hupp Corporation, representing the R. C. H. car; Foster Motor Sales Co., the Church-Sibley Co., the manufacturers of the Paterson Car and others.

S. A. E. Party Ready to Sail Home

Advices cabled from Paris by Coker F. Clarkson, secretary and general manager of the Society of Automobile Engineers, make the announcement that the delegation from the society which has been spending a month inspecting British and Continental factories and engaging in scientific conferences will sail for New York on the steamer *Olympic* November 29.

Mr. Clarkson says that the visit has been a great success in every way, and that the foreign manufacturers have done everything possible to assist the visitors. Not all the party will return on the *Olympic*, as quite a number will remain abroad for several weeks longer to make more detailed inspections and to go into fields not touched by the regular itinerary. Plans for the annual meeting of the society are being matured and it is expected that the Madison Square Garden program will include forty or more formal papers in which the commercial vehicle will come in for considerable consideration.

Solid Tire Patent in Federal Court

Orders issued by the United States Circuit Court in the suits of the Consolidated Rubber Tire Co. against the Goodrich, Republic Rubber and Morgan & Wright companies, based upon the alleged infringement of the Grant patent on solid tires, allow each of the three defendants 60 days in which to plead to the complaints.

The suits were instituted about two years ago and have lain practically dormant pending a decision of the patent by the Supreme Court. This was handed down last spring, and now the present suits will be determined.

The complaining company alleged that the Grant patent was valid and belonged to it and charged that the defendants infringed it. Preliminary injunctions were issued and the cases will be tried upon their merits, probably at the spring term of court. The plaintiff company seeks permanent injunctions, an accounting with each defendant and damages.

Rubber Sellers Sue Michelin

Echoes of the explosion of the late rubber bubble were heard in New York last week when Poel & Arnold entered seven suits against the Michelin Tire Co. based upon alleged contracts of sale made during the period of market inflation in the early part of 1910. It is charged by the complaining company that the defendant refused to accept the rubber sold and that in consequence of the falling market since that period the sellers lost a considerable amount.

The matters will hardly be ready for trial until next spring.

What S. A. E. Tourists

LONDON, Nov 20—How London secures the best cab service in the world at a lower price than any other city was revealed in a visit which the members of the Society of Automobile Engineers made to the depot of W. & G. Du Cros, Ltd. London possesses between 7,000 and 8,000 motor cabs plying for hire at the uniform rate of 16 cents for the first mile and 4 cents for each additional quarter mile.

Messrs. W. & G. Du Cros operate 1,200 cabs and always have 1,050 in use, the remainder being in the depot for overhauls and repairs. Napier has supplied 800 of the chassis and Panhard 400, all being four-cylinder models of practically 80 by 120-millimeter bore and stroke. The organization is such that the cabs are in service every day. There is one driver per cab, the system of double shifts having been found to be unsatisfactory, and each driver must keep his cab out 12 hours per day.

Payment is made on the basis of 25 per cent. of the net takings, the driver buying his gasoline from the company at cost price, 18 to 20 cents per gallon, and being provided free with everything else necessary for running. It is the company's task to so organize their depots that no cab shall be kept off the street except for the periodical overhauls.

It was explained to the visitors how, after coming in at night, every cab was got ready for the road the next morning, no matter what its condition, after a hard day's work punctuated with accidents. Only a complete wreckage of the cab would necessitate its stoppage in the depot for more than one night. In addition to washing, inflating tires, filling tanks, oiling, touching up paint work, etc., the organization is so good that such serious damage as the breakage of the crank hangers, the rupture of the differential or the changing of the gearbox could be repaired between midnight and 10 o'clock the next morning. The company buys its own tires, of 815 by 105 millimeter section, and by a systemized method of nightly examination and repair whenever necessary can get a much higher average in the hands of rough drivers than is possible by many private car owners. Two steel-studded tires are used, one on the rear, and the other on the opposite front wheel.

Each cab travels from 60 to 80 miles a day, two-thirds of this distance being on paying trips. The minimum earnings are $8 per day, of which amount the driver will keep $2. Depreciation is based on a period of seven years, and, according to the engineer in charge, the cabs which have already been in service three and one-half years are in every respect equal to new. The cabs cost from $1,500 to $1,700 complete. The recording instrument is not included in the amount, this being rented from the taximeter manufacturing companies.

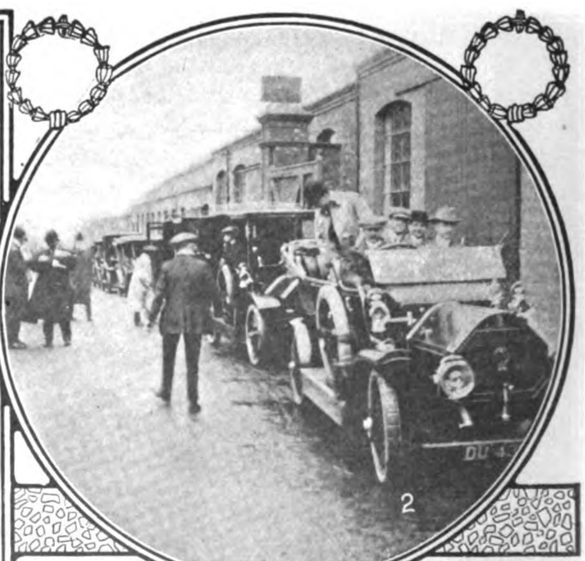
One hundred and forty persons, about forty of whom were members of the Society of Automobile Engineers, united at the Trocadero restaurant, Piccadilly, London, for the banquet given by the Institution of Automobile Engineers in honor of the visit of the Americans. The chair was occupied by L. A. Legros, M.Inst.C.E., and president of the Institution of Automobile Engineers. After the toasts of the King and the President of the United States had been cordially honored, F. W. Lanchester proposed the Society of Automobile Engineers, and H. F. Donaldson replied. The Institution of Automobile Engineers was proposed by Howard E. Coffin, and replied to by Dr. H. S. Hele-Shaw. "Our Guests" was proposed by T. E. Browne, and replied to by Edward B. Ellington and Sir George Gibb.

Typical London November weather prevailed when, at 11 o'clock on Sunday morning, about 20 Ford cars called at the headquarters to carry the entire party to Brooklands motordrome, about 20 miles out of town. The showers, however, were unable to damp the spirits of the party, and even the arresting of C. H. Foster, president and general manager of the Gabriel Horn Company, and a couple of the Ford drivers for exceeding the speed limit only served to add interest to the run.

Lunch was taken at The Hut, Wisley, a typical English hostelry on the road from London to Portsmouth, and the run was continued to the track, where a couple of hours were spent in racing over the cement surfaced speedway, climbing the 25 per cent. test hill, and examining the unique timing apparatus.

After six days in London practically the entire party moved northward to Coventry, a town which may very accurately be described as the Detroit of Great Britain, for it is here that about three-quarters of the English factories are situated. A number of automobiles being in waiting, the visitors were taken direct to the Humber factory, and after presentation to the general manager, H. G. Burford, were shown through the works. Originally devoted to bicycle construction, the Humber factory now produces automobiles, motorcycles and bicycles, the number of cars produced being about 2,000 per year, and the number of motorbicycles 4,000 to 5,000 a year. A staff of 3,000 men is employed.

The stop for lunch at the Hut on the way to Brooklands.



Leaving the Humber factory, Coventry

Saw on British Trip

The high standard of factory management, and the comparative youthfulness of the heads of important departments came as a surprise to some of the members of the party, who had expected to find other conditions. The prodigality of labor, compared with American methods, was noted, but was readily understood in view of the lower rates of wages paid. Among the features which attracted attention were the water brake for engine testing, and the use of a chain for driving the camshaft of the Humber motors. It was explained that the practice was to use a Coventry chain which had been run in on a jig for a fortnight without a stop, this being equal to road service of 10,000 miles. There would be a stretch of one-sixteenth of an inch on the length of the chain, but after this treatment no further stretch would take place, and no provision for taking up slack was provided on the motor. The Humber company entertained the engineers at lunch at the King's Head Hotel, under the chairmanship of D. F. Basden, president of the company, supported by Ballin Hinde, vice-president, and H. G. Burford, general manager. On the afternoon of the same day a visit was made to the works of Alfred Herbert, Ltd., one of the largest machine-tool makers in England.

The greater portion of the second day's visit to Coventry was spent at the Daimler Company's factory, the first one in Britain to be devoted exclusively to automobile construction, and at present the largest in England, the output being about 3,200 cars a year, and the entire staff numbering nearly 5,000 men. As is generally known, the Daimler Company of Coventry produces Knight motors to the entire exclusion of the poppet-valve type, the motors being built for their own cars and for several other firms holding the Knight license but not yet in a position to produce sleeve-valve motors. These large Diesel motors used for generating current attracted particular attention, as did also a gasoline-electric bus with two Knight motors, one on each side of the frame, with separate drive to each rear wheel.

For the second time the visitors were entertained at luncheon, the hosts on this occasion being the Daimler Company, represented by Percy Martin, vice-president, in the chair, supported by E. M. C. Instone, the business manager, and by Charles Y. Knight. In replying to the toast of "The Guests," proposed by Mr. Knight, H. F. Donaldson echoed the sentiments of the whole party when he declared that they had considered London the apex of cordiality, for they had been received as cousins; but at Coventry they had been welcomed as brothers. A busy afternoon was occupied in visiting the wire wheel factory of the Rudge-Whitworth Company, where sets of wire and wood wheels were tested to destruction; examining the plant of the Coventry Chain Company, the makers of most of the chains now used for driving camshafts, and a run through Warwick, Kenilworth and Stratford-on-Avon in Daimler cars supplied by Mr. Knight.

Birmingham tried to outdo Coventry in the matter of hospitality. When the members of the Society of Automobile Engineers arrived at the works of the Wolseley Tool & Motor Company they found the Stars and Stripes flying side by side with the Union Jack and an open house and a glad welcome within

Very close attention was paid by the visitors to the cutting of worm gears for final drive, the Wolseley company using the worm for its 12 and 16-horsepower models, and bevel gears for all the larger types. It was declared that the efficiency was equal on the two types, and that they had been able to make the bevel just as silent in action as the worm; this was due in a large measure to the method of hardening each tooth of the crown-bevel wheel separately under an oxy-acetylene flame. Each wheel is mounted in a bath so that it can be revolved, and the tooth just on the surface of the water is operated upon with the flame. It is declared that by this method all possibility of distortion of the bevel wheel is removed. The new case-hardening rooms with the pyrometer going direct to the laboratory, thus removing all responsibility for the temperature from the workmen, were examined with interest.

The bench tests of the motors are carried out in the usual way and as soon as a motor is passed as satisfactory it is torn down, examined and washed piece by piece under a powerful jet of kerosene. Each chassis is taken on the road by three different testers, all of whom must fill in a very detailed report covering practically every portion of the mechanism, and stating the road and weather conditions which obtained during the tests.

When the car has been declared satisfactory it is again pulled down, examined for traces of wear, and finally assembled. Although building in series, the factory pays close attention to individual requirements in the matter of the body and fittings.

After the visit to the factory the officials of the Wolseley Company entertained the visitors at luncheon at the Grand Hotel, Birmingham, the president on the occasion being Mr. MacCormack, general manager of the company, supported by Max R. Lawrence, works manager, and Mr. Royce.

First American Road Congress Meets

RICHMOND, Nov. 23—The 4-day convention of the first American road congress of the recently organized American Association for Highway Improvement, ended in this city this afternoon with the election of officers for the coming year. The sessions proved to be of interest from start to finish. Over 500 delegates from all of the states and territories of the Union attended and the discussions following the different addresses proved how much attention is being devoted at present to the good roads movement. The two opening days of the convention were given over to the road builders, many of the leading civil engineers of the country being present. In fact, more of these attended than at any previous road congress. A novel feature of the convention, and one which appealed especially to motor car owners, was the third day, which was known as road users' day. The program for it was handled by the Touring Club of America, and it had gathered together several of the leading legal lights in the country who have to do with automobile legislation, as well as not a few of the leading car manufacturers. Among the legal representatives were Edward Lazansky, Secretary of State, New York; Matthew S. Rogers, Secretary of State, Connecticut; and Highway Commissioner Colonel William D. Sohier, of Massachusetts. In the automobile manufacturing field were Colonel Clifton, president of the Automobile Board of Trade, and Hugh Chalmers. Major Richard Sylvester, president of the International Police Association, spoke on the regulation of traffic in cities. Other speakers were Sidney S. Gorham, Chicago, and Preston Belvin, president of the Virginia Automobile Association.

Special interest attached to the addresses of Colonel Sohier and also of Secretary Lazansky, both of whom presented statistics to show the present status of the motor car in their respective states and sections. In the year 1901 there were 954 cars registered in the Empire state whereas this year there were upwards of 85,000 cars registered. Nearly 34,000 chauffeurs have been registered.

Basing his calculations on these figures the speaker showed that to-day there is approximately $85,000,000 invested in cars in the state and that a little over $42,000,000 is expended annually in maintaining these.

In speaking on the number of cars owned throughout the country, Secretary Lazansky based his figures on the data obtained from the government figures which showed up to the present, a registration in thirty-five states of approximately 517,000 cars, of 174,000 registered chauffeurs and total receipts from registrations of $3,746,938.

Colonel Sohier spent most of his time on showing the number of cars in use in Massachusetts as compared with horse vehicles and also proving the point that motor vehicles cause many fewer accidents per mile traveled than trolley cars. He brought out the amazing fact that horses are decreasing in city use in the big cities but gaining in use in the country, but when the totals are looked into it is found that the horse is on the decline so far as numbers in use in Massachusetts are concerned.

Colonel Clifton was reminiscent of the early days of motoring to show the conditions of roads when the New York-Buffalo and New York-Pittsburgh tours took place. He used this as a basis for showing that since the inception of the automobile industry the car maker has always taken the attitude of co-operation with the different good roads organizations. He showed that contests have done much to stimulate the good roads cause as well as the actual building of good roads.

Hugh Chalmers showed how that the automobile is not the only industry that is benefited by good roads but cited how it costs 23 cents a mile to handle a ton of goods on the American roads as compared with less than 10 cents a mile on European roads. On some of the English roads entering London where motor trucks are used, the cost is less than 4 cents a mile. If the freight bill of this country could be cut in half it would mean a saving to the people of $250,000,000 a year. In speaking of the cost of building modern roads in different sections of the country, he brought out the fact that in North and South Carolina macadam roads can be built for $1,800 per mile; and that in nine states in the South the average cost of macadam roads approximate $4,000 per mile. In southern Ohio bituminous macadam roads cost $7,000 per mile; in Massachusetts the average macadam road costs $8,000 per mile and in New York State the new roads are costing $9,000 per mile. Ohio has some brick roads which cost from $10,000 to $14,000 per mile.

Following is an extract of Colonel Sohier's address on motoring conditions in the State of Massachusetts:

It may be well to consider what the character of the travel that is using our highways at particular points is, and how that travel is likely to develop in the future. In 1909 the Massachusetts highway commission made a traffic census of the vehicles using state highways. The passing vehicles were actually counted at 240 stations upon our state highways scattered throughout the state for 14 hours a day, 7 days in August and 7 days in October. They were classified into heavy and light horse-drawn vehicles, and the motor vehicles were divided into touring cars and runabouts. At that time the motor truck had not appeared. I insert a table which gives a summary of this traffic census.

The actual count showed that on some of the roads the motor vehicles, even at that time, constituted 90 per cent. of the traffic, and in several instances over 1,100 cars a day passed a given point. A census was taken at certain places in the parkways near Boston, and this count showed over 60 per cent. automobile travel and over 3,000 automobiles a day. Even at that time, therefore, on many of our highways, especially on the main routes, it was found that the motor vehicle constituted more than one-half of the travel.

Average Daily Traffic—All Stations

	August Census	October Census
Horse-drawn:		
Light	19,622	16,456
Heavy	17,969	17,967
Total	37,591	34,423
Automobiles:		
Runabouts	5,922	3,995
Touring cars	21,387	14,514
Total	27,309	18,509
All kinds	64,900	52,952
Per cent. horse-drawn	58%	65%
Per cent. automobile	42%	35%
Average per station:*		
Horse-drawn:		
Light	83	69
Heavy	76	75
	159	144
Automobiles	115	77
All kinds	274	221

*In August 237 stations; in October 240 stations.

Accidents on Our Streets and Highways

Automobile accidents throughout the country were receiving an undue share of notoriety. They were given scare headlines in the papers, partly because this is a new means of locomotion and partly because of the prominence of the people occupying the automobiles. I think this matter will be of some interest to you. Please remember that of all the automobile accidents which we were able to hear of and record, 960 of the total of 1,182 accidents in 1910 occurred in city streets. In other words, four accidents occurred in city streets to every one in the country.

During the year ending November 30, 1910, according to the report of the police commissioner, the following number of people were killed and injured in the streets, parks and squares of Boston:

Total number of people killed	94
Total number of people injured	2,025
Due to traffic:	
Deaths	50
Injuries	1,022

In other words, only one-half of the deaths and only one-half of the injuries were due to traffic. Very few of these injuries were due to fire engines, bicycles or trains, so these figures are omitted.

Deaths and Injuries by Traffic

Total number of deaths		50
Due to horse-drawn vehicles	15, or 30%	
Due to trolley cars	22, or 44%	
Due to automobiles	13, or 26%	
Total number of injuries		1,022
Due to trolley cars	383, or 37½%	
Due to horse-drawn vehicles	359, or 35 %	
Due to automobiles	280, or 27½%	

In this same period of time various other accidents were due to other causes, by far the largest of which was falls resulting in twenty-three deaths and 777 injuries.

In other words, there were nearly twice as many deaths and nearly twice as many injuries in the streets of Boston which were due to people falling in the street and being injured than were due to motor vehicles. It is a little hard to make comparisons, because the *numbers* of electric cars, horse-drawn vehicles and automobiles is not really a fair criterion. The mileage should also be taken into account.

Increase in Motor Vehicles

To make a comparison today, we should consider the growth of the number of automobiles using our streets:

In 1903, 3,241 automobiles were registered in Massachusetts.
In 1909, 23,902 automobiles were registered in Massachusetts.
In 1910, 31,347 automobiles were registered in Massachusetts.
In 1911, 38,677 automobiles were registered in Massachusetts.

At least 5,000 dealers' cars are registered as well. Since our traffic statistics were taken the number of automobiles registered in the State has increased over 60%.

Decrease in Horses

In Massachusetts, in 1909, about 169,000 horses were assessed, and in 1910 about 165,000. In this one year the number of horses assessed had decreased 4,000, and the number of automobiles registered had increased 7,400. Undoubtedly, there is more of a change this year.

I merely put in these figures as preliminary to further consideration of to what extent the automobile is responsible for the accidents which occur on our highways. It is evident today that they constitute fully 50% of all the vehicles that are passing over our highways.

Trolley Cars and Motor Vehicles

It is interesting to compare upon this basis of mileage the accidents occasioned by trolley cars and the accidents occasioned by automobiles. The trolley car mileage and accidents are both official figures taken from the railroad commissioners' report:

TROLLEY CARS:—Miles Traveled	87,712,572
Fatal Accidents:	
Passengers and employees	28
Outsiders	78
Total	106
Injuries:	
Passengers and employees	5,273
Outsiders	1,917
Total	7,190
MOTOR VEHICLES:—Miles Traveled	185,806,000
Fatal Accidents:	
In Motor Vehicles	25
Outsiders	52
Total	77
Injuries:	
In Motor Vehicles	378
Outsiders	585
Total	963

Assuming that the above mileage for motor vehicles is correct, we should have the following results:

Number of Miles Traveled by Trolley Cars and Motor Vehicles to Each Ensuing Accident

	Trolleys	Motor Vehicles
Miles per accident to anyone, including fatal cases	12,053	178,660
Miles traveled per fatal accident	827,477	2,413,065
Miles traveled per injury	12,199	192,945
Accidents to Persons Who Are not Employees or Occupants of Cars:		
Miles traveled per accident	44,389	291,689
Miles traveled per fatal accident	1,124,520	3,573,192
Miles traveled per injury	45,755	317,617
Accidents to Employees and Occupants of Cars:		
Miles traveled per accident	16,546	461,057
Miles traveled per fatal accident	3,132,449	7,432,240
Miles traveled per injury	16,634	491,577

Automobile Legislation in Massachusetts

No person can operate an unregistered motor vehicle and no person can operate a motor vehicle without having received a license from the Massachusetts highway commission.

The commission *may revoke* a license, after due hearing, for any cause it may deem sufficient; and it *may suspend* a license, without a hearing, whenever it has reason to believe that the holder thereof is an improper or incompetent person to operate motor vehicles or is operating improperly or so as to endanger the public; and the license shall not be reissued unless the commission, upon examination or investigation, or after a hearing determines that the person should again be permitted to operate.

In 1908 the commission was authorized by law to investigate automobile accidents. Whenever a death results from any such accident, the commission *shall suspend* forthwith the license of the operator of the motor vehicle involved, and it *shall revoke* said license unless after an investigation or hearing, it determines that the accident occurred without serious fault upon the part of the operator.

The commission *shall revoke* the license of a person three times convicted of overspeeding in any one calendar year; and no new license may be issued to such a person until after the expiration of a period of 30 days from the date of the third conviction. Acts of 1909. The commission *shall revoke* the license of any person convicted of operating a motor vehicle recklessly, or while under the influence of intoxicating liquor, or so as to endanger the lives or the safety of the public; or upon a bet, wager, or race; or for the purpose of making a record; or of going away without stopping and making himself known after causing injury to person or property; or of using a motor vehicle without authority; and no new license shall be issued to any such person before the expiration of a period of 60 days from the date of conviction nor thereafter except in the discretion of the commission.

The commission, by law, has the right to appoint investigators and examiners. It has appointed seven such investigators and examiners and they are among the most competent men of their class to be found anywhere. These examiners examine every chauffeur before he receives a license. He is required to pass a written examination and also to pass a severe operating test on the road.

Examinations held in 1910	5,433
Number of persons examined	4,138
Number of persons receiving licenses	3,701
Number of persons failed on first examination	1,268
Number of persons refused a license after several examinations	437

In other words, over 10% of all the persons examined failed to receive a license, and nearly 25% of all the persons failed to pass upon the first examination.

Investigation of Accidents

During the year 1910 its investigators made investigation and reported 429 accidents. In that year 283 licenses or registration certificates were revoked or suspended. The causes of these revocations and suspensions were shown in the following table:

Reckless operation	50
Operating while under the influence of intoxicating liquor	22
Accidents resulting in death	57
Improper operation	88
Refusing or neglecting to stop after accident	9
Three overspeeding convictions	8
Operating automobiles without owner's permission	23
Other offenses	26
Total	283

Motor Vehicle Accidents

The following table of accidents which occurred in Massachusetts in 1909 and 1910 may be of interest:

	1909	1910
Total number killed	54	77
Total number injured	989	963
Total number of accidents	1,130	1,182
Total number of accidents in daytime	826	867
Total number of accidents after dark	304	315
Total number of accidents on country roads	314	222
Total number of accidents on city or town streets	816	960

In 10 months of the year 1911, there were 1,229 such accidents. In this connection, it must be remembered that in 1909 something under 24,000 automobiles were registered in Massachusetts and that in 1911 (allowing only five cars for each dealer) there were something over 42,000 automobiles registered. In other words, the number of automobiles using our highways has increased in that two years something over 60%. The number of accidents has only increased about 10%.

Causes of Accidents

It may be interesting to see what, in the opinion of the commission, after careful investigation and report upon all the evidence, was the cause of some of the more serious of these accidents. I have made an abstract of a few of the more serious accidents for 10 months of this year—from December 1, 1910, to October 1, 1911, as shown by the following table:

Total number of accidents investigated and acted upon	278
Operator without fault	110
Other party to accident more to blame than operator, but operator not blameless	20
Operator more to blame than other party to accident, but latter at fault also	24
Operator entirely to blame	114
Both operators equally to blame	10

You will note that after a full investigation, involving a statement taken from all of the witnesses and a careful report from our investigator, and consideration by the commission, in nearly 40% of all of these accidents the operator was not to blame.

As a result of the discussion, the committee on resolutions selected by the Touring Club of America recommended and secured the adoption of the Road Congress of the following suggestions for traffic regulation:

WHEREAS, the safety of the public is of primary importance, and the driving of vehicles at night is attended by dangers which should be reduced to a minimum;

Now, therefore, Be it further *Resolved*, That it is the sense of this Congress that from sunset to sunrise, all vehicles should carry at least one lighted lamp of sufficient candle power to be visible at a distance of 200 feet, so placed as to be seen from the front and left side, and a red light visible in the reverse direction, and

Be it further *Resolved*, That the use in cities and villages of non-dazzling headlights on all vehicles should be required by law, wherever the streets are adequately lighted, and

WHEREAS, the highways within the confines of the cities, towns and villages, as well as in the open country, are dedicated to the public use,

Now, therefore, be it *Resolved*, That all users of said highways should have due regard for the rights of other users, the pedestrian for the rights of horse-drawn vehicles, the drivers of horse-drawn vehicles for the rights of the drivers of motor vehicles, the drivers of motor vehicles for the rights of cyclists, the cyclists for the rights of equestrians, and one and all for the rights each of the others, and

Be it further *Resolved*, That the use of the muffler cut-out in thickly settled sections and in cities should be discontinued, and

Be it further *Resolved*, That the unnecessary use of warning signals should be avoided, and that an adequate warning signal should produce an abrupt sound, sufficiently loud to be heard under all conditions of traffic, nd that its use except as a warning of danger should be prohibited by law, and

Be it further *Resolved*, That in cities, towns and villages, slow-moving vehicles should be required to drive close to the curb in order that the faster moving vehicles may pass in the center of the thoroughfare, and

Be it further *Resolved*, That in view of the fact that the motor vehicle is used for interstate communication, frequently passing through two or more states during a single day, uniform speed regulations should be adopted by all states, and local authorities, such as cities, towns and villages, should be prohibited from fixing local speed regulations, and

Be it further *Resolved*, That in view of the rapid development of commercial motor trucks for inter-city use, the public authorities charged with the duty of building and maintaining bridges should be required periodically to inspect all bridges under their jurisdiction and post conspicuously thereon the wheel load they are capable of sustaining, and

Be it further *Resolved*, That in view of the unprecedented growth of interstate and inter-city motor traffic for commercial purposes, a systematic a d adequate placarding of roads by sign-boards, giving directions as to towns and distances should be required by law, and such laws strictly enforced.

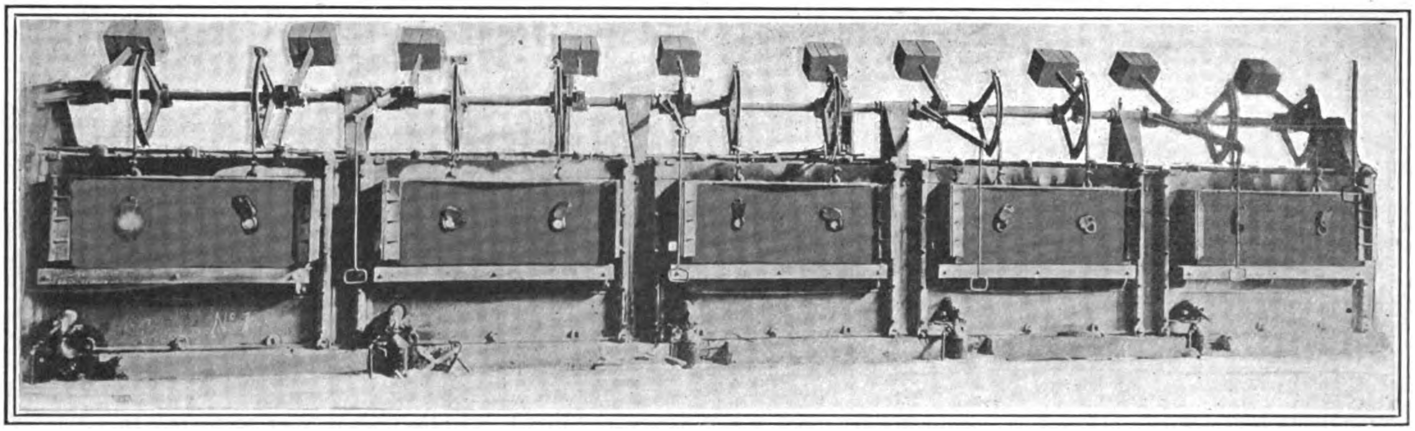

Fig. 1—View of the five new casehardening furnaces installed at Warner plant at Toledo

Equipment for Heat Treatment

CASEHARDENING and special heat treatments enter so widely into the field of making automobile parts that the Warner Manufacturing Company, of Toledo, Ohio, which makes steering, transmission and differential gears, has found it necessary to install a large new plant for this purpose. The equipment of this plant comprises five casehardening furnaces Fig. 1 which are arranged in battery form, and two heat-treating furnaces, and it was designed by Walter Macleod & Co., of Cincinnati, Ohio. Included in the plant are also a steel fan pressure blower, which is directly connected to a motor, a rotary oil pump geared to the blower shaft, and a Taylor multiple indicating pyrometer outfit. Furthermore the equipment includes a 13,000-gallon oil tank, pipes and gauges, and a motor for determining the fuel consumption.

In order to get the maximum amount of work out of the furnaces with the least expense involved, it is necessary to have this equipment designed in the most efficient fashion. All seven furnaces contained in this plant are made of high-class fire brick, encased in heavy sectional cast-iron ribbed plates which are held in their relative positions by means of bolting strips and tie rods. The combustion chamber, in each furnace, is located adjacent to the heating space and the construction of the former space is such as to permit of proper distribution of the gases carried to the heating-chamber arch, so that the charge is heated effectively, yet in a protected position. After heating the material the gases pass into flues in the walls.

Taking into account the tendency of hot gases to rise, the combustion chamber is so constructed as to permit the hot gases to fill it and then to escape, under a uniform pressure, through the ports to the heating chamber. The pockets leading thereto are fire-brick lined. The hearth is a solid foundation of common standard-shape fire brick. The fuel used being oil, an oil burner is stationed in front of the furnace parallel with the combustion chamber, while an auxiliary air blast enters on the opposite end. This blast is controlled by a valve directly under the burner.

In the casehardening furnaces, the heating chambers are each 54 by 72 inches, while in the heat-treating furnaces Fig. 2 they are 32 by 40 inches. The casehardening furnaces have, at 1560 degrees Fahrenheit, a capacity of 190 sets of transmission gears per day of 24 hours. Average penetration of hardening is 1-32 inch.

The variation in temperature in a combustion chamber is not more than 30 degrees Fahrenheit.

Oil and air used for heating are supplied by a unit Fig. 3, composed of a No. 8 A. B. C. steel fan pressure blower which is directly connected to a 15-horsepower electric motor by a flanged coupling.

The oil pump is constructed for the so-called suction-return system and is fitted with check and relief valve, pressure gauge and all other necessary accessories. The pyrometer outfit used is the product of the Taylor Instrument Companies.

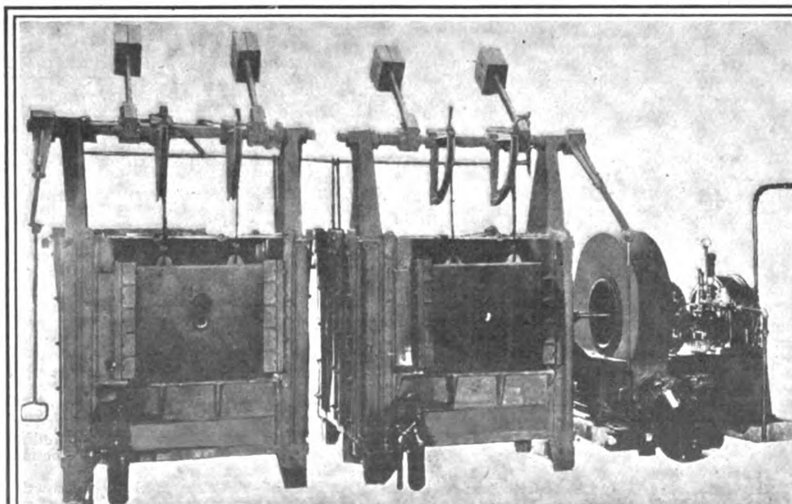

Fig. 2—Two heat-treating furnaces and motor operating them.

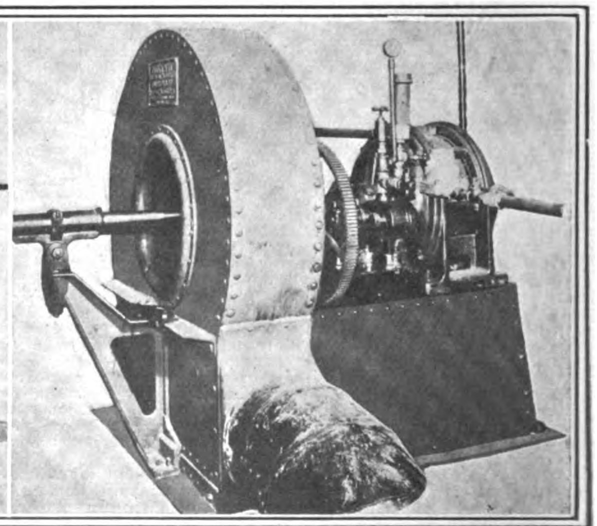

Fig. 3—Steel fan pressure blower and motor

Service Buildings Open in New York

THE F. B. Stearns Company, of New York City, has just opened extensive quarters for the accommodation of its patrons, whose cars are in a state to be repaired. The rapid growth of the concern's business was the cause of the old repair department at 227 West 57th street proving too small for the increasing need, so that the company had to go to the construction of more spacious premises.

The new service department, which in its entirety is devoted to the repair and overhauling of Stearns products, is located at 415 West 55th street. The building, which is shown in the accompanying illustration, is six stories high, these lofts, in addition to a basement, being equipped in a most up-to-date manner in order to take care of the work that comes in. The space is about 40 x 100 on each floor, making a total of about 30,000 square feet.

On the ground floor is stationed the office, and here too the cars make their way to the elevators lifting them to the higher floors. The entrance from the street is wide enough to permit the heaviest trucks to enter. The second floor contains the stock room, with a complete stock of Stearns repair parts. This department takes up almost half of the floor, while the other half is used for overhauling purposes. The next higher floor houses the machine shop and the automobiles, while such repairs are executed upon them as necessitate the proximity of the shop. The other floors are used for storing and assembling work, as well as for general tuning-up work.

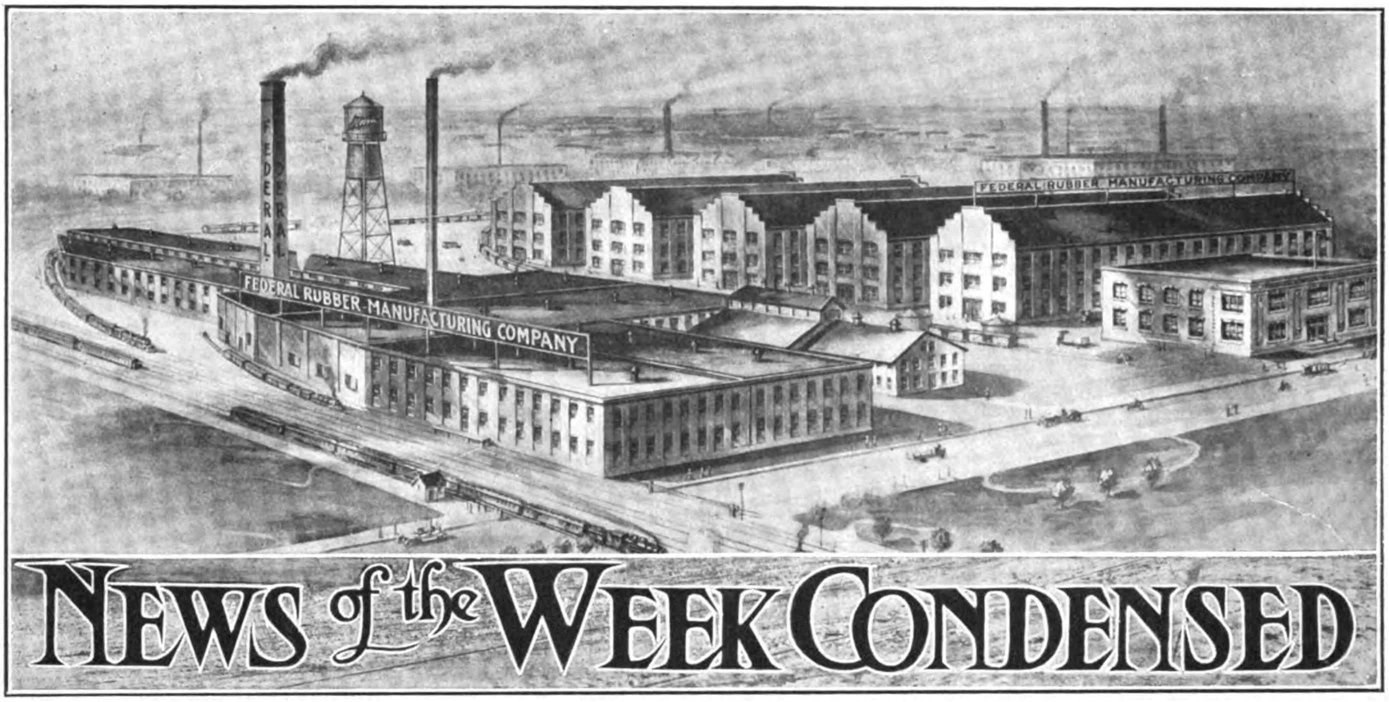
When some weeks ago the finishing touch had hardly been put on the building, the workmen of the company were already busy on the various machines in the building. The building had been opened but for two days and already there were about two dozen automobiles there, expecting speedy treatment. A corner of the third floor is shown, with two cars being worked on and part of the machine shop in sight.

Beautiful new Stearns and Mitchell Buildings

Automobile companies find this neighborhood a most suitable one to install their service departments in, and it may safely be predicted that within a short time many concerns will follow the example set by Stearns and others. This is foretold by the fact that the Mitchell corporation has opened a service building adjacent to the Stearns department, which is seen on the left of the upright illustration. The space occupied by the Mitchell works is about the same as that used by the Stearns people. The New York home of the Saurer trucks is situated at the right of the Stearns building.

At foot West 57th street, the White Company is just finishing its new service department. This is a ground-floor affair, with no upper stories, but it has almost as much total area as the Stearns place, being 100 by 240 feet large. Like the other building, the White place is constructed of reinforced concrete. The lighting system demands special comment, in that plenty of light is available at every place in the building. This is accomplished, not by a full-glass roof, but by placing the roof surface at two levels and connecting these by huge vertical windows permitting lots of light to enter the interior. The White building also serves only as a service department, and no garage work is done in it.

The interior of the Stearns repair shop is spacious and adequately lighted



Bird's-eye view of the new plant of the Federal Rubber Manufacturing Company at Cudahy, Wis.

CUDAHY, WIS.—Since the announcement by the Federal Rubber Manufacturing Company last July of its acquisition of the plant formerly operated by the Federal Rubber Company in this city, and of its purpose to enlarge and remodel the property throughout, this work, in charge of the Westinghouse-Church-Kerr Company, has been rushed night and day. The Federal plant is located on a five-acre tract on the main line of the Chicago & Northwestern Railroad. It is provided with ample switching facilities for the economic handling of its raw material and for the distribution of its finished products.

KIRBYVILLE, TEX.—M. Singletary of this city is to open a garage and machine shop.

SANFORD, ME.—The Ford Auto Co. has taken the agency for the 1912 line of Pullman cars.

LOWELL, MASS.—Frank E. Harris has taken the agency for the Oldsmobile in this vicinity.

TRENTON, N. J.—Harry Stout, 12 and 14 East State street, has added the Pullman car to his line of 1912 models.

SANDUSKY, O.—The Sandusky Auto Parts & Motor Truck Co. has increased its capital stock from $150,000 to $500,000.

NEW BRITAIN, CONN.—T. W. Crowe has been awarded the contract for the garage to be erected by the New Britain Gas Light Co.

MILWAUKEE, WIS.—The Goodyear Rubber & Tire Co. has established a branch at 134-136 Oneida street. H. P. Ziegler is manager.

PHILADELPHIA.—Settlement was made recently by the Automobile Club of Philadelphia for a site for a two-story clubhouse and garage.

MILWAUKEE, WIS.—Edwin J. Groth, 1125 25th street, has been appointed distributor of the Crown positive safety lock for motor cars in this territory.

HAMBURG, GERMANY.—The Ford Motor Co. of Detroit, Mich., U.S.A., has opened a branch in this city. The European trade of the company continues to expand.

SAN ANTONIO, TEX.—The Taxicab Co. of this city has changed its name to the Transfer & Taxicab Co., and has increased its capital stock from $15,000 to $30,000.

AKRON, O.—M. H. Pletcher will handle the Pullman 1912 line in Summit county. Mr. Pletcher will also establish a number of Pullman agencies throughout the state.

PITTSBURGH, PA.—Plans have been completed for a two-story brick and reinforced concrete garage and sales building to be constructed in the East End for the White Co. of Cleveland, O.

HARRISBURG, PA.—According to statistics announced this week by the Pennsylvania state highway department over 44,000 licenses have been issued by the automobile license division up to the present time.

GENEVA, N. Y.—The ferry across Cayuga Lake has been discontinued for the season, making it necessary to use the Montezuma Swamp road via Free Bridge. The road is in passable but dangerous condition.

PORT WASHINGTON, WIS.—The Kraus & Grau Hardware Co. has been appointed Ozaukee county agent for the Cutting, Westcott, Herreshoff and National lines, which are represented in Wisconsin by the Wisconsin Auto Sales Co., 114 Mason street, Milwaukee.

WYOMING, ILL.—E. H. Brown, Stark County agent for the Studebaker, E-M-F and Flanders cars, is planning extensive enlargements and improvements to his garage on Main street this winter. Mr. Brown has again contracted for the Studebaker lines for the coming season.

DETROIT, MICH.—R. E. Fair, manager of the Lion Motor Sales Co., has closed a contract with the Farmers' Handy Wagon Co. of Saginaw for 35 Lion 40s. The Saginaw concern has purchased the cars for the use of their salesmen, who will thus be able to cover their respective territory more thoroughly than by depending on trains and livery rigs.

DETROIT, MICH.—The Republic Rubber Co. of Michigan has been incorporated and will handle the full line of automobile and motor truck tires manufactured by the Republic Rubber Co. of Youngstown, O. The local salesroom and office will be located at No. 1001 Woodward avenue, with C. P. Foley, formerly with the local branch of the Firestone Tire & Rubber Co., in charge.

FREEPORT, ILL.—A. H. Kloepping & Co. have taken over the Bijou Garage on Douglass avenue and will handle the Studebaker lines in Stephenson County for 1912. While the main office of the new concern will be in Freeport, branches will be established in Orangeville, under the management of A. M. Snyder, at Rock City under the management of A. H. Kloepping, and the Freeport end will be handled by George Mitchell. Branches will also be established at German Valley and Pearl City.

CHETEK, WIS.—Harry E. Johnson has established a garage here.

RACINE, WIS.—The Racine Automobile & Motor Works will represent the Buick line in this territory.

AUGUSTA, WIS.—Julius Walthenpuhl has been appointed district agent for the Imperial and is now erecting a garage.

PORTLAND, ORE.—The Rose City Garage of Portland has taken the Oregon distribution of the Baker electric machines.

CINCINNATI, O.—The Eddy Auto Co. is erecting a $10,000 one-story concrete and brick automobile garage on May street.

SYRACUSE, N. Y.—The James Auto Co. will handle the Central New York territory for the Hudson Motor Car Co. of Detroit.

WAUSAU, WIS.—The L. H. Hall Co., agent for the Chalmers line for several years, has become exclusive agent for the KisselKar.

MONDOVI, WIS.—R. P. Goddard, Jr., has been appointed local agent for the Jackson, and has completed work on a new garage building.

LOUISVILLE, KY.—The Louisville Automobile Co., local agent for the Hupmobile, has acquired the agency for the Van Dyke trucks in this territory.

KEWASKUM, WIS. — The John W. Schaefer & Sons Co. is erecting a new garage here. The company will represent the Overland line in several counties.

SEATTLE, WASH.—Fred M. Powell has become identified with the Hugh A. Baird Co. of this city in the capacity of sales manager. The Baird Co. handles the Reo, Franklin and Apperson cars.

CINCINNATI, O.—C. H. Linson, manager of the Motor Car Supply Co. has severed his connection with that company and will go to Minneapolis, Minn., to act as branch agent for the Republic Tire Co.

SYRACUSE, N. Y.—The Velie Motor Vehicle Co., through the Kerr-Doane Motor Co. of this city, has established the following agencies for Velie cars: Norwich, Binghamton, Hornell, Elmira, and Ithaca.

MOBILE, ALA.—The Sowell Auto Co. will conduct the garage formerly operated by the McMain Motor Car Co. The Sowell Co. is composed of Walter Sowell and D. C. Sowell, formerly of Wallace, Ala., and Richland, Miss.

DETROIT, MICH.—A. J. Rousseau, who has been identified with the General Motors Co. for some time, has been appointed sales manager in charge of the western district for the Imperial Automobile Co. of Jackson, Mich.

LOUISVILLE, KY.—The business of the Ford Motor Co. of Detroit has been increasing so rapidly in Kentucky through their Louisville agent, the Banks Motor Car Co., that the factory established a permanent branch here this week.

NEW YORK CITY—George Armstrong, representing Carlos Armstrong, E. Hijos, Playa-Ponce, Porto Rico, on a recent trip to this city, arranged with the Colt-Stratton Co., Cole eastern distributor, to handle the Cole car in Porto Rico.

WHITE SALMON, WASH.—A new bridge is to be built over the river near here to accommodate the heavy loads which will be hauled by 5-ton automobile trucks used in transporting material for the construction of the new concrete dam.

NEW YORK CITY.—The Motor Car Equipment Co. is opening an uptown branch in addition to its main headquarters at 55 Warren street. The branch is located at 238-40 West 56th street, and will be ready for business about the December 10.

NEW YORK CITY.—The American Express Co. has a fleet of fifteen Packard 3-ton trucks in service in this city. After several years of experiment the company has found that the automobiles are cheaper and more efficient than horses in delivery work.

OMAHA, NEB.—S. A. Zapp and J. F. Lohrmann of Fremont have contracted with the Racine Sauley Co. to handle the Nyberg and Columbus cars in their territory. The Casey Auto Co. of Casey, Ia., will also handle the Nyberg cars.

SYRACUSE, N. Y.—F. R. Bump, who was formerly general sales manager of the H. H. Franklin Mfg. Co. of this city has become assistant general manager of the R. C. Hupp organization. Mr. Bump has recently been with the Universal Motor Truck Co.

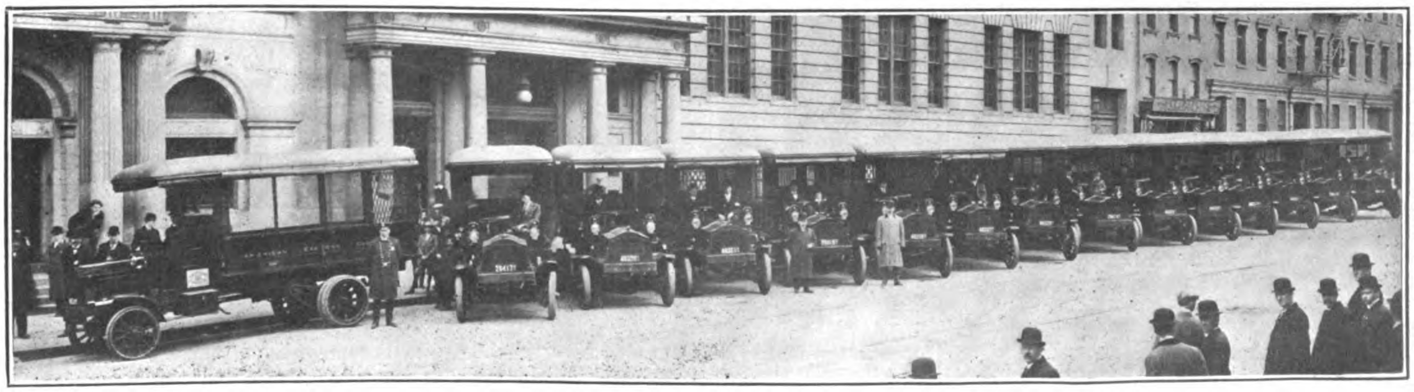
TOLEDO, O.—A new concern has been organized in Toledo to be known as the Ignition Starter Co. It has quarters in the Nicholas building. H. A. Cavanaugh and J. M. Ewing are the promoters of the business. They will equip cars with the Disco self-starter.

KENOSHA, WIS.—Richard H. Welles is at the head of the company which intends to provide the city of Kenosha with motor bus service. Mr. Welles states that the service will be inaugurated about December 1. The service will extend over the entire city, along regular routes, and will be operated winter and summer.

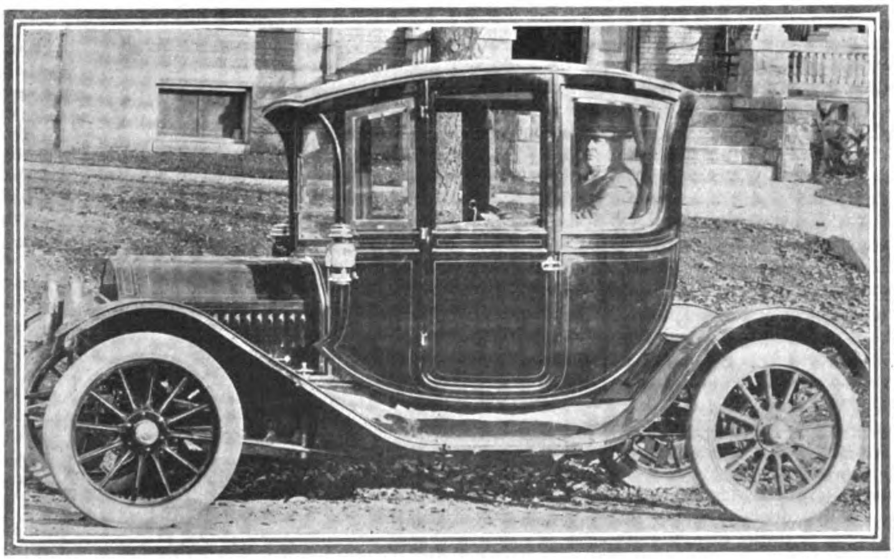
MILWAUKEE, WIS.—Recent agency appointments by the Hickman-Lauson-Diener Co., Milwaukee, state agent for the Ford, include: Marathon Motor Car Co., Wausau; Arthur Voss, Mukwanago; G. H. Hafemeister, Watertown; August Prange, Sheboygan; F. C. Behlendorf, Oshkosh; T. W. Twining, Gays Mills; John Hieligenthal, Lyons.

CINCINNATI, O.—Ira D. Cooper, formerly with the Morgan & Wright Tire Co., has left that organization and formed the Cooper Rubber Co., with the aim of distributing tires throughout Ohio, Indiana, Kentucky, and West Virginia. The new company will also handle its own line of bicycle, buggy, vehicle and solid motor tires. J. R. Burgamy, late of the Coughlin & Davis Co., has associated himself with the new firm.

INDIANAPOLIS, IND.—George Lehnert has been appointed receiver for the Star Motor Car Co. of this city by Judge Collier of the Superior Court. Action asking the appointment of a receiver was brought by Theodore M. Weiss, a stockholder, who alleges the concern is insolvent. The company was organized and incorporated in November, 1909, for the purpose of manufacturing motor cars but has never built but one car. Offices have been maintained in the Lemcke building.



Packard 3-ton trucks in the service of the American Express Company in New York City



President G. A. Matthews, of the Jackson Automobile Co., in his new coupé

HAGERSTOWN, MD.—R. Bruce Carson has taken the local agency for the Cole car.

KEWANEE, ILL.—The Kewanee Garage has been appointed agent for the Cole car.

FOND DU LAC, WIS.—The Auto Tire & Repair Co. has been appointed agent for the Rambler line.

MOSCOW, IA.—The Moscow Automobile Co. has been organized here to distribute the Cole car in this vicinity.

SAN FRANCISCO, CAL.—F. W. Burgers, formerly connected with the Phoenix Rubber Co., will hereafter handle the Batavia tire in this territory.

MILWAUKEE, WIS.—Bonow Bros. have taken over the Boulevard Garage at 266-268-270 Twenty-sixth street and will handle the Nyberg line of cars in Milwaukee county.

PORTLAND, ORE.—Showing the rapid increase in the number of automobiles now in Oregon, the total number of automobiles in this state in July, 1909, was 2100. Now there are over 6500.

RACINE, WIS.—Amended articles of the Mitchell-Lewis Motor Co. were filed with the register of deeds recently. Amendments provide for sixteen directors instead of ten as heretofore.

SYRACUSE, N. Y.—Representatives of the Knox, Rambler, White and Premier automobiles, which now have no agencies in the city, are now here, and it is stated that agencies will be established in a few days.

DETROIT, MICH.—The Detroit Public Library has established a branch at the factory of the Packard Motor Car Co. This step was taken in consideration of the fact that more than 7,000 persons are employed there.

JACKSON, MICH.—The Jackson Automobile Company has brought out a new model. It is a 40-horsepower coupé with 118-inch wheelbase and 34-inch wheels. The car, which is electrically lighted throughout, has the steering wheel on the left and the control levers in the center.

MOLINE, ILL.—The Midland Motor Co. of this city, manufacturers of the Midland car, recently appointed the following new agents: Lewis Sales Co., 3950 Olive street, St. Louis, Mo.; Carrigan Bros., 1006 Olive street, Los Angeles, Cal.; Wm. Easton & Son, Austin, Nev.; Farmers' Exchange & Implement Co., Price, Utah.

GALESBURG, ILL.—Callender & Petrie will handle the Rambler line in this vicinity, with headquarters in Galesburg and a sub-branch in Ophiem. A new garage and salesroom is now being fitted up for them on Prairie street, which will be modern in every respect and ready for occupancy in a short time.

SYRACUSE, N. Y.—The following have been recently appointed agents for the Franklin car: Woodhouse-Lough Co., Plainfield, N. J.; W. A. Worley, Jacksonville, Fla.; C. G. Meyer & Son, Tiffin, Ohio; Fruit-Ohl Co., Sharon, Pa.; Barber & Hunter, North Adams, Mass., and H. B. Sproul & Co., Staunton, Va.

SYRACUSE, N. Y.— Julian Brown, son of the prominent manufacturer, A. T. Brown, of this city, announces that he will soon erect a factory for manufacturing the gas engine recently invented by him and which is attracting a great deal of attention in the trade. Mr. Brown will have plenty of financial backing. The factory site is not yet selected.

NEW YORK CITY.—In referring to the increase of the capital stock of the Thomas Motor Cab Co., of Buffalo, N. Y., from $50,000 to $100,000 in our issue of November 16 an unfortunate typographical error made it appear that the company in question was the Thomas Motor Car Co. of that city. As is well known, the capital of this company is $2,400,000.

BOSTON, MASS.—The Franklin Co. has decided to give up its branch in Boston and hereafter it will be conducted as an agency. O. A. Lawton, who for some time has been manager of the branch, has decided to take the Franklin on as an agency proposition, and for the present he will have his salesrooms at 31 Irvington street. He has the New England territory.

MARINETTE, WIS.—The United Car & Sales Co. has been organized here by Myron Churchill and Harold Scott, to do a general agency and garage business at 1351 Main street. The concern will represent the Buick and KisselKar lines. Alex Nordquist will be in charge of the garage and shops. Messrs. Churchill and Scott recently established the Marinette School of Motoring here.

DETROIT, MICH.—A. F. Mais, recently vice-president and chief engineer of the Mais Motor Truck Co. of Indianapolis, has resigned as chief engineer of the Mais company and accepted a position as consulting engineer for the Studebaker Corporation, E-M-F company. The old Ford plant located near the E-M-F factory in Detroit has been absorbed by the Studebaker corporation and converted into an experimental department. Mais is in charge of this department, which is known as plant No. 10. His office as vice-president of the Mais Motor Truck Co. is still retained together with his interest in the concern.

MILWAUKEE, WIS.—Efforts are being made by garage-keepers in Wisconsin to arrive at a uniform scale of rates for storage, washing and polishing. The accepted schedule is as follows: Two to five-passenger cars: storage, 50 cents; per month, $15.00; washing, $1.00; polishing, 50 cents. Seven-passenger cars: storage per day, 75 cents; per month, $20.00; washing, $1.50; polishing, 50 cents. Limousines: storage per day, 75 cents; per month, $20.00; washing, $2.00; polishing, 50 cents; use of wash-rack, $1.00. Electric pleasure cars, per day, $1.50; per month, including washing, polishing and charging, $32.50. A uniform scale of prices for gas and oils is also to be made.

GALESBURG, ILL.—Hobbie & Martin, who for the past three years have been associated in the general garage business and as territory distributors for the Buick line for the surrounding counties, have dissolved partnership. The Buick line will be carried by W. C. Hobbie, who will have practically the same territory, while W. P. Martin, as manager and owner, will retain the garage located on Seminary avenue. Mr. Hobbie will open a salesroom in the business district with a small garage in connection. George Sperry, who has been with Mr. Hobbie for the past two years, will become his partner, and will take up the sale of Buick cars in Knox, Henry, Warren, and Mercer counties.

YORK, PA.—The Townsend Auto Co. of Easton, Md., has taken the agency for the 1912 line of Pullman cars.

SAO PAULO, BRAZIL.—S. Kremer Sobrinho has become the agent for the Pullman cars in this country.

AKRON, O.—The Cuyahoga Realty Co. will erect a $17,000 garage and storage room at 41-45 North High street.

WOODBINE, IA.—F. C. McCann has secured the agency for the Nyberg car from the Racine-Sattley company of Omaha.

DULUTH, MINN.—W. J. Gorgon is now associated with the Interstate Automobile Co. as a member of the sales force.

BALTIMORE, MD.—James M. Easter is having plans prepared for a garage which he intends to erect at 2100 Eutaw Place.

JACKSONVILLE, FLA.—W. C. Thomas, of the Jacksonville Regal Motor Agency, has secured the agency for Florida for the Haynes car.

GLOUCESTER, MASS.—Perkins & Corliss, the local garage owners, have recently taken the agency for the Ford in this city, Manchester, Essex and Rockport.

NEW YORK CITY—The American Rim Co. has taken quarters at 250 West Fifty-fourth street, where it will handle the Lambert demountable and quick detachable rim.

CHICAGO, ILL.—N. Lazarnick, of New York City, the pioneer automobile photographer, has opened a branch office and studio at 509 South Dearborn street, in this city.

WALTHAM, MASS.—The Motors Specialties Company of this city has discontinued its Boston office and has removed it to the factory where all departments will be under one roof.

BOSTON, MASS.—Hugh Miller has been made resident manager of the Aristos Co., distributors of the Disc-Self-Starter, with offices and salesrooms at 1002 Boylston street.

LOS ANGELES, CAL.—Mr. Gehricke has been appointed manager of the local branch of the Stromberg Motor Devices Co., of Chicago, Ill., at 945-947 South Main street.

DEFIANCE, O.—Edward and John Compo have purchased the large business of the Miller Machine Co. The garage will be conducted in the future under the firm name of Compo Bros. Garage.

BOSTON, MASS.—The Velie Boston Branch is to remain in its present headquarters at 92 Massachusetts avenue throughout the 1912 season, the report that a removal was contemplated being incorrect.

PHILADELPHIA, PA.—At the annual meeting of the Quaker City Motor Club, to be held early in December at the Hotel Walton, Clarence Cranmer will be appointed to the secretaryship, vice A. T. James, resigned.

New salesrooms of the Waverley and Elmore agents at Detroit, Mich.

BOSTON, MASS.—Manager Chester I. Campbell, of the Boston Automobile Show, with Mrs. Campbell, sailed last week for a trip to Europe where he will look over the foreign shows and compare them with the American ones.

PORTLAND, ME.—G. A. Blanchard has taken on the Selden car for this section of Maine, the agency having been closed a few days ago by John D. Murphy, eastern traveling representative of the Selden company, who is now touring the New England states.

BOSTON, MASS.—W. H. Vinal, who organized the Motor Car Co. of Boston and was president of the corporation, has resigned and disposed of his stock to S. S. Anderson. The Motor Car Co. has the New England agency for the Nance six. Mr. Vinal has not made any plans for the immediate future, but he expects to embark in the motor industry later on with a combined pleasure and commercial line. L. W. Abbott has been made sales manager of the company.

Automobile Incorporations

AUTOMOBILES AND PARTS

BOSTON, MASS.—Fothergill Motor Co.; capital, $100,000; to sell and make freight automobiles. Incorporators: R. B. Skinner, A. C. York.

CHARLESTON, OHIO.—Collison-Pierson & Co.; capital, $25,000; to buy and sell automobiles. Incorporators: J. F. Collison, D. R. Pierson, W. S. Taylor, O. H. Ashley, A. B. Koontz.

CHICAGO, ILL.—Harder Autotruck Co.; capital, $100,000; to manufacture motor trucks. Incorporators: Henry P. Chandler, J. M. Johnson, K. Cornwall.

DALLAS, TEX.—Oldsmobile Co.; capital, $10,000; to sell automobiles. Incorporators: Rupert E. Paris, R. N. Mosher, Clinton C. Clark.

DUBUQUE, IA.—Dubuque-Rambler Auto & Supply Co.; capital, $20,000; to sell automobiles and accessories. Incorporators: Arch Frater, B. M. Fitzgerald, W. E. Ellwanger.

INDIANAPOLIS, IND.—Pedalmobile Mfg. Co.; capital, $2,500; to manufacture automobiles. Incorporators: Geo. Herff, J. F. Minthorne, A. T. Purcell, P. A. Porteous.

LOUISVILLE, KY.—Transit Motor Car Co.; capital, $20,000; to manufacture and repair automobiles. Incorporators: E. C. Walker, Geo. H. Laib, W. B. Young.

MEMPHIS, TENN.—Tri-State Auto Co.; capital, $1,000; to sell automobiles. Incorporators: J. F. Hignan, R. L. White.

NEWARK, N. J.—Lenox Motor Car Co.; capital, $25,000; to sell automobiles. Incorporator: Louis Lippman.

NORFOLK, VA.—Virginia Automobile & Repair Corporation; capital, $10,000; to sell and repair motor cars. Incorporator: H. L. Page.

TOLEDO, OHIO.—Royal Auto Co.; capital, $1,000; to sell automobiles and equipment. Incorporators: Marion H. Kennedy, E. B. Parker, B. C. Christen, E. J. Heise, E. M. Warnke.

TOLEDO, OHIO.—Moore Motor Truck Co.; capital, $10,000; to build and deal in motor trucks. Incorporators: D. W. Bliss, E. L. Skidmore, C. H. Rauch, E. F. Moore.

URBANA, ILL.—Illinois Motor Car Sales Co.; capital increased from $12,000 to $25,000.

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

BUFFALO, N. Y.—Herkimer Garage Co.; capital, $10,000; to conduct a general garage business. Incorporators: Rowland J. Conover, Robert E. Conover, Louis K. Jillson.

CARROLLTON, OHIO.—Carrollton Rubber Co.; capital, $10,000; to deal in crude rubber and rubber goods. Incorporators: Homer J. Richards, John H. Richards, J. R. Williams, James C. Oglsvee, Wm. H. Miller.

CHICAGO, ILL.—Empire Top & Supply Co.; capital, $20,000; to manufacture automobile equipment. Incorporators: Henry Graff, Jr.; Albert N. Charles, Joel E. Bullard.

CINCINNATI OHIO.—Auto Accessories Mfg. Co.; capital, $15,000; to make automobile accessories. Incorporators: S. C. Roettinger and others.

FORT WAYNE, IND.—Merchants Motor Delivery Co.; capital, $25,000; to conduct a transfer business. Incorporators: A. W. Harris, W. Han, A. H. Fernwalt.

INDIANAPOLIS, IND.—Co-Operative Automobile Supply Co.; capital, $25,000; to deal in supplies. Incorporators: B. H. Rifenbark, J. C. Curtis, J. H. Boesinger.

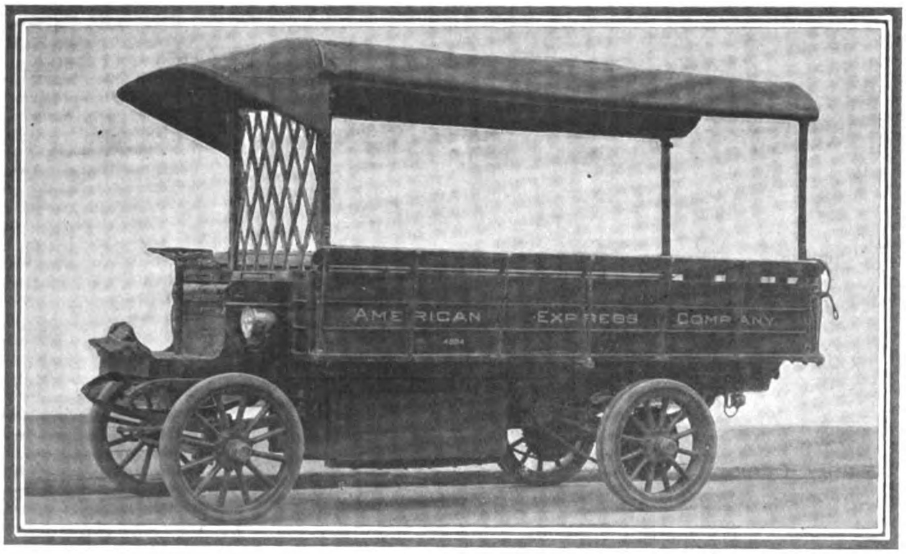
PITTSFIELD, MASS.—Pittsfield Auto Garage Co.; capital, $3,000; to operate a garage. Incorporators: Mary I. Mills, Arthur A. Mills, Arthur J. Mills.

PUNXSUTAWNEY, PA.—Cole Automobile & Transfer Co.; capital, $10,000; to do a general transfer business.

ST. LOUIS, MO.—Curtis Jack & Trust Co.; capital, $75,000; to manufacture combination jacks and hand trucks. Incorporators: J. R. Curtis, H. C. Flunker, A. W. Smith.

WASHINGTON, PA.—American Tire & Filler Co.; capital, $200,000; to manufacture and sell automobiles. Incorporators: Jas. S. Forsythe, F. C. Lewis, H. J. Johns, R. D. Forsythe, E. W. Rolfe.

OF INTEREST to the INDUSTRY



One of the fifty Baker electric trucks ordered by the American Express Company

CLEVELAND, OHIO.—An order for fifty electric trucks has been placed by the American Express Company with the Baker Motor Vehicle Company, of this city. For several years the express company has been experimenting with delivery systems using both horses and motor vehicles with the result that the motor-truck system has been found the more satisfactory.

TULSA, OKLA.—Tulsa's first automobile factory will be turning out cars by January 1. The factory is that of the Dowagiac Motor Car Company, of Dowagiac, Mich.

SCHENECTADY, N. Y.—The Nordyke & Marmon Company, of Indianapolis, Ind., has ordered eighty-two induction motors of the General Electric Company, of this city.

DETROIT, MICH.—The Krit Motor Car Co. has just shipped fifty cars to Great Britain and twenty-three to other foreign countries. The company is devoting more attention to its export trade than formerly.

TOLEDO, OHIO—Machinery is being installed at the new plant of the Electric Auto-Lite Company in the rear of the offices at 135-137 Michigan street. Officers are A. W. Fisher, president; S. L. Kelly, vice-president, and C. Q. Miniger.

FINDLAY, O.—The Universal Machine Company is removing from Toledo to Bowling Green. The new factory has a floor space of 22,000 feet and will be used for the manufacture of the Toledo marine engine. By the first of the year the company expects to manufacture parts for the Modern Motor Car Company.

LA PORTE, IND.—The establishment of a factory to manufacture radiators for plowing engines and possibly automobiles in this city is practically a certainty, and it is expected to erect a factory building this fall. E. H. Scott and Dr. Edward A. Rumely are largely interested in the project.

DETROIT, MICH.—The Anderson Electric Car Co. shipped its first trainload of Detroit Electrics from the factory recently. The company has many orders ahead and is running full time. Ten models are being manufactured this year, one of the latest being a roadster with a 96-inch wheel base, a wheel steer and a control device on the wheel.

NORWALK, O.—The affairs of the bankrupt Norwalk Motor Car Company are rapidly being wound up by Trustee A. J. Schur before Referee in Bankruptcy Benjamin B. Wickham. Recently a sale of the remaining assets of the company was made to the Model Gas Engine Company, of Peru, Ind., the largest individual creditor, the account being something over $5,000.

DETROIT, MICH.—The recently organized Chevrolet Motor Car Co., which has started clearing ground out Woodward avenue for a large plant, has elected officers as follows: President, William H. Little, of Flint, Mich., formerly general manager of the Buick plant; vice-president and treasurer, Dr. E. R. Campbell; secretary, Curtis R. Hathaway; designer and consulting engineer, Louis Chevrolet; assistant secretary and treasurer, W. W. Murphy. The company will manufacture the Chevrolet Six.

DETROIT, MICH.—Contracts were let recently for a large addition to the Scripps Motor Car Co.'s plant on Clinton street and work is already under way. Work is also about to start on the Hupp Motor Car Co.'s new plant at Milwaukee and Mt. Elliott avenues. The plans have been prepared by architects Dunlap and Palmer and the contracts let. Thus the company will have new factories going up on both sides of the river at the same time, ground having been broken for its Canadian branch in Windsor, Ont., some time ago.

INDIANAPOLIS, IND.—The Motor Starting Company has been organized here to manufacture a self-starting device. Quarters have been taken at 427 North Meridian street and factory arangements are to be made immediately. The device consists of a hand air-pump and small carbureter located on the floor near the driver's seat, with a tube running to each cylinder head. A mixture, consisting of one drop of gasoline to sixty-five parts air, is pumped into the cylinders and a spark causes sufficient combustion to start the motor. Lew W. Cooper is president.

DETROIT, MICH.—The pay-rolls of the Packard Motor Car Co. for the month of August, 1911, amounted to $524,407, probably the largest sum ever paid in wages by any one automobile factory in a single month. At that time there were 7,575 employes at work in the Packard shops. Five buildings were under construction to provide additions to the present floor space of 33 acres. This pay-roll of the company has increased to the enormous figures shown above from $16,278 in August, 1894, and for the fiscal year of 1903 and 1904 the pay-roll was less than for the month of August, 1911. The fiscal years of 1910 and 1911 showed a pay-roll amounting to $443,152.

DETROIT, MICH.—Honors are about even between the Herreshoff Motor Car Co. and the citizens who have been fighting the company in the courts, in an effort to prevent the establishment of a motor car plant in a fashionable section of Woodward avenue. In the Recorder's court last Thursday Judge Connolly denied a motion made by the company's attorneys to quash the condemnation proceedings instituted by the citizens interested. In the Wayne Circuit court the following day Judge Donovan refused to issue an injunction restraining the building operations, which at no time have been suspended since they were begun several months ago. The factory is now well along and the probabilities are that operations will have started by the time the condemnation proceedings are heard. It is almost certain that the case will go to the Supreme court for final adjustment.

PATENTS GONE TO ISSUE

CARBURETER—Gasoline vaporizer of the single-chamber type.

2. This carbureter has a casing (Fig. 1) which is open at the top and has a lateral discharge opening near the upper end and a gasoline inlet near the lower end, where also a number of openings are provided. Near its upper end the casing is enlarged to form an annular extension into which the outlet merges. A valve is provided for the inlet with a perforated disc connected to it, and an annular screen in the housing, which forms the inner wall of the extension, has inwardly directed lips. A closure for the upper end of the casing engages upon the lips mentioned and holds the screen in position.

No. 1,009,252—to Michael E. Mallo, Greeley, Colo. Granted November 21, 1911; filed November 26, 1910.

CLUTCH—Of the multiple-disc type directly connected to the transmission.

2. The patent covers the combination with a variable-speed transmission gearset of a clutch casing detachably secured to the front of the gearbox and supported by the same. A clutch shaft stepped at its rear end in the end of the transmission shaft and at its front end in a bearing in front of the clutch casing has universal joint secured to its front end, a multiple-disc mechanism inside the clutch casing connecting transmission shaft and clutch shaft. Means are provided on the clutch casing for operating the multiple-disc friction mechanism within the casing.

No. 1,009,702—to John G. Utz, Detroit. Mich. Granted November 21, 1911; filed November 22, 1910.

AUTOMOBILE WHEEL—In which rocking members and an elastic medium take the place and office of compressed air used in a pneumatic tire.

1. This wheel includes a rim on which a series of annular members is mounted which may rock independently of their relation to the rim. The terminal portion of each member fits snugly between the terminal portions of the adjoining members and movable relative to them. The terminal portions are connected by elastic means controlling the movement of the members, and they support a tread.

No. 1,009,088—to Charles S. Myers, Columbia, Pa. Granted November 21, 1911; filed September 27, 1910.

SHOCK ABSORBER—Friction between contacting discs is used to absorb shocks caused by road inequalities.

4. This patent relates to a shock absorber (Fig. 2) in which a rotary shaft is mounted inside a case and projecting from it to the outside. On the shaft, within the case, a packing gland is mounted, and a disc is also mounted on the shaft. Loose friction plates are provided on each side of the disc. A screw cap is provided for the case, and an annular spring is placed between one of the friction plates and the screw caps.

No. 1,009,454—to Harry C. Turner, Los Angeles, Cal. Granted November 21, 1911; filed August 21, 1907.

STARTING VALVE—A device for starting internal combustion engines without mechanical effort.

1. In this device (Fig. 3) a valve is located in a valve casing and its stem extends through a guide way, being operated by the engine, while the valve admits compressed air from a supply pipe through a conduit to a second valve parallel to the first. From the second valve the compressed air is admitted behind the engine piston to start the same, the first valve being automatically thrown open and out of operation when the air is cut off from communication therewith.

No. 1,009,626—to Baxter M. Alakson, Salem, O. Granted November 21, 1911; filed October 14, 1907.

DEMOUNTABLE RIM—A number of male and female inequalities in rim and felloe serve to insure engagement of the latter.

3. The patent covers a demountable rim and wheel structure comprising a coned wheel felloe embraced by a frustro-conical band, and a cylindrical wheel rim provided with depressions which carry a removable pneumatic tire sliding over the larger base of the frustro-cone. A wedge ring is secured to the inner front face of the rim and bears against the felloe band to close the open joint betwen rim and felloe. Outwardly projecting screws in the felloe engage with the rim depressions, thus keeping the rim in place on the wheel.

No. 1,009,103—to Robert P. Scott, Cadiz, Ohio. Granted November 21, 1911; filed June 15, 1909.

TRANSMISSION MECHANISM—Shaft drive combined with a live rear axle.

2. This mechanism comprises two rotary power transmitting wheels, a wheel fixed longitudinally and laterally with respect to one of the power transmitting wheels, and removable means for fixing the same to the other power transmitting wheel.

No. 1,009,435—to Ralph L. Morgan, Worcester, Mass.

SPARK PLUG.—Containing electrodes for both high- and low-tension currents.

1. The igniter covered by this patent comprises a hollow bushing carrying a low-tension electrode, which supports a high-tension electrode separated from it.

No. 1,008,178—Carl Messersehmid, New York, N. Y., assignor to The Duplex Magneto & Spark Plug Co., Brooklyn, N. Y. Granted November 7, 1911; filed January 6, 1911.

Newest Ideas Among the Accessories

Jacobson Air Compressor

THE Jacobson air compressor, Fig. 1, is of the garage type built by the Jacobson Machine Mfg. Co., of Warren, Pa. It is designed with the object of meeting the specific need of automobile

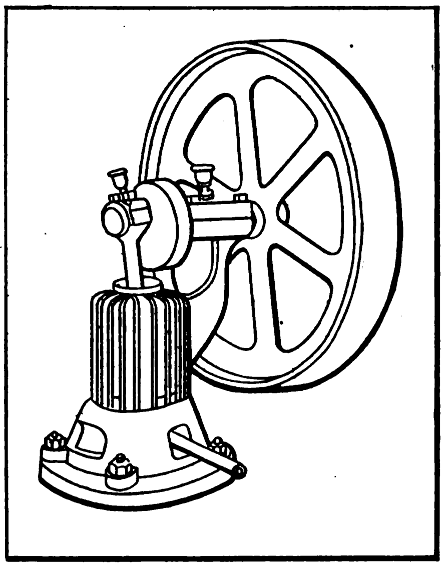

Fig. 1.—Jacobson air compressor

owner or garage operator, by a combination of maximum capacity with minimum volume and weight. As Fig. 1 shows, this type has a cylinder which is air-cooled and cast in one piece with the bearing housing. The bore of the cylinder is 3 inches and the stroke 4 inches, and 200 revolutions of the crank are equivalent to 3½ cubic feet of air delivered by the compressor. The piston, which has three expansion rings, is of the trunk pattern, and the valves are made of a special grade of bronze. The bearings are made adjustable so as to overcome the effects of wear, and all parts are made in standard dimensions for the sake of interchangeability. The flywheel by which the engine may be driven is crowned for this purpose, but a small driving pulley may be procured with the machine, if this type of drive is preferred to the one by the flywheel. The weight of the machine is 200 pounds and the total floor space occupied by it 20 by 24 feet.

Federal Auto Washer

The Federal Auto Washer is shown installed in a garage in Fig. 3. The advantages of this system are that it is attached to the ceiling and, while it has a considerable range of action, will not be found to be in anyone's way in the garage. The top piece is held to the ceiling by four screws, and from it is suspended by a supporting arm and an elbow, a horizontal pipe, 4 feet 4 inches in length. This pipe may be turned in any direction, being connected to the top portion, into which the pipe from the water main leads, by a connection of standard dimensions. A rubber hose is attached to the end of the vertical pipe, and the other end of the hose carries a nozzle by means of which a stream of water may be directed against the body of the car. The flow of the water is regulated by a gate valve interposed at the wall in the branch of the water mains supplying the water, but it is also possible to use a nozzle with another valve permitting of the operator's starting and stopping the water while standing by the car. This washer is manufactured by the Walworth Mfg. Co., 132 Federal street, Boston, Mass., which is also acting as distributor and selling agent for the New England States.

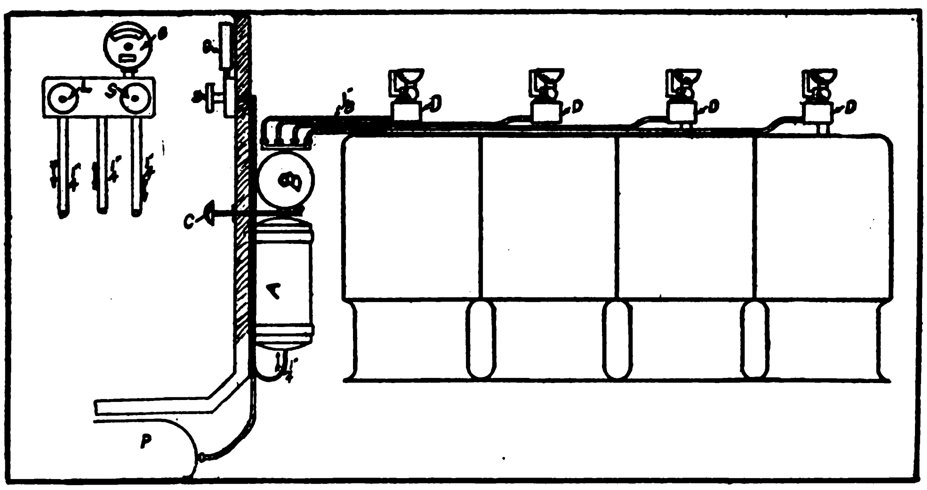

Fig. 2.—American self-starter system

American Self-Starter

The American Self-Starter is one of the systems in which acetylene derived from the gas tank is used to start the automobile engine on the spark. The system is installed in the manner illustrated in Fig.

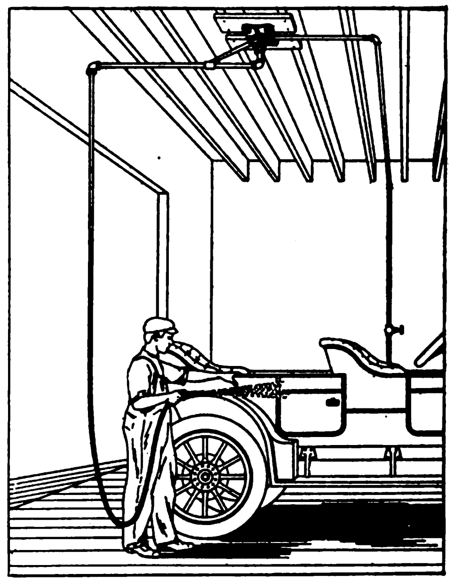

Fig. 3.—Federal Auto Washer

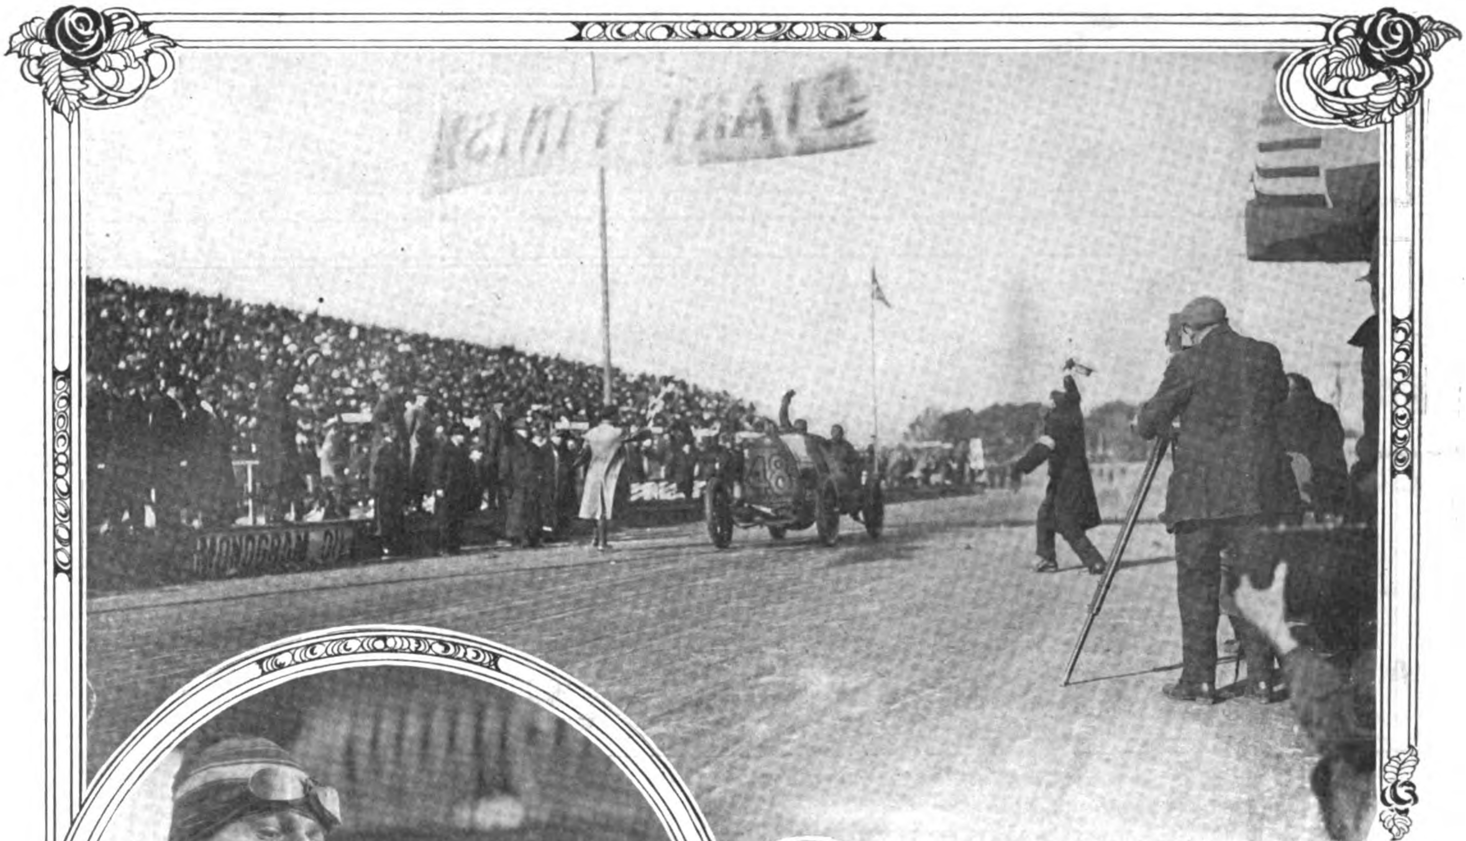
2. The pressure tank A is installed on the front of the dashboard and securely fastened thereto. The push rod C extending from it should be in a position easily reached by the driver's foot. Then the priming cups are removed from the cylinders and the check valves D inserted in their places, and the controller with valves L for regulating the lights, and S for admitting gas to the starter is installed upon the dashboard. Valve L is connected with the lamps and S with the check valves in the cylinder heads, and connection is also made between gas tank P and needle valve B of the pressure tank A. For the latter purpose the maker of the starter supplies ⅛-inch brass tubes and patent lead packing for all joints and unions. Metal clasps are used to tie the tubes together to prevent rattling. For starting G the controller valve S is turned by its handle until the gauge above the controller registers 30 pounds pressure in the pressure tank; then the push rod C is pressed, releasing the compressed gas from the tank and directing it into one or two of the cylinders, whereupon the spark is thrown on. This process, it is claimed, will start the engine in any weather. The American Self-Starter system is handled in the New England States by the New England Sales & Equipment Co., 100 Boylston street, Boston.

VOL. XXV NEW YORK—THURSDAY, DECEMBER 7, 1911—CHICAGO No. 23

THE AUTOMOBILE

Fiat, Bruce-Brown, Wins Grand Prize



Scene When Bruce-Brown in the Winning Fiat Crossed the Tape in the Grand Prize at Savannah. The Winning Driver and His Mechanician

SAVANNAH, GA., Nov. 30—David Bruce-Brown, in a Fiat special racing car, to-day won the Grand Prize race after one of the most spectacular struggles ever seen in a road race in America. In this struggle Eddie Hearne, in a Benz, Ralph De Palma, in a Mercedes, and Ralph Mulford in a Lozier, were his greatest rivals. Brown put his Fiat over the 411.36 miles at an average pace of 74.45 miles per hour, scarcely 1-2 mile an hour faster than the Vanderbilt was won on the same course 3 days before. Brown won by the narrow margin of 2 minutes and 2 seconds over Hearne in the Benz; De Palma, in his Mercedes, was third, being but 3 minutes and 9 seconds back of the Fiat. Bragg, who finished fourth in a Fiat, was 20 minutes back of Brown.

Mulford, in the Lozier, was less than 2 minutes behind Brown at the end of the twenty-second lap, but he went out in the first part of the twenty-third lap, due to breaking of the main shaft extension of the gearset.

The winning Fiat, getting away after a stop at the pits

Brown's average of 74.45 miles an hour sets a new record for road races of this distance in America. By to-day's victory he was enabled to claim equal honors as a road race repeater with Harry Grant, winner of the Vanderbilt cup race last year, when he won it for the second successive time in an Alco car; and also with Thery, the celebrated European driver, who won the Gordon-Bennett race in 1904 and again in 1905 in a Brasier car.

Brown's victory this year was popular. Being the winner of the Grand Prize last year he was a strong favorite, with the masses and much speed was expected from his Fiat racer. His great rivals to-day before the race started, were Wagner in another Fiat and Victor Hemery in a Benz. Last year Hemery was but 1.32 seconds behind Brown, the year before he was but a few seconds behind Wagner who won in a Fiat, and this year many were looking to him to carry off the laurels. It was known in practice that he had the fastest car on the course and this was proved to-day when he made the fastest lap, averaging 81.61 miles an hour for a circuit. But luck was against him good and strong to-day. In the third lap he broke an exhaust valve and was over one hour making the circuit, which eliminated him as a contender, but he effected a repair and made seven laps when he was compelled to retire, due to the same trouble. Wagner, the winner of the grand prize race 2 years ago, was looked upon as a probable leader to-day, in fact, more expected him to win than Bruce-Brown, but he, too, was doomed to disappointment. He had many cases of tire trouble and in taking a turn too fast in the fourteenth lap ran off the course and damaged his steering-gear and withdrew when he reached the grandstand. With his elimination the two great European drivers were out and the American speed pilots on foreign and domestic cars were left to wage the battle.

A cursory analysis of the performance of Brown in his Fiat will show what difficulties he had to contend with from start to finish. His task was not that of defeating Hearne, or Mulford or De Palma, but at different stages of the contest he had to battle with the speedy Wagner, with the equally speedy Bragg, with the speed king Hemery, with Patschke and with Burman. He ran second for the first three laps, then dropped to eighth

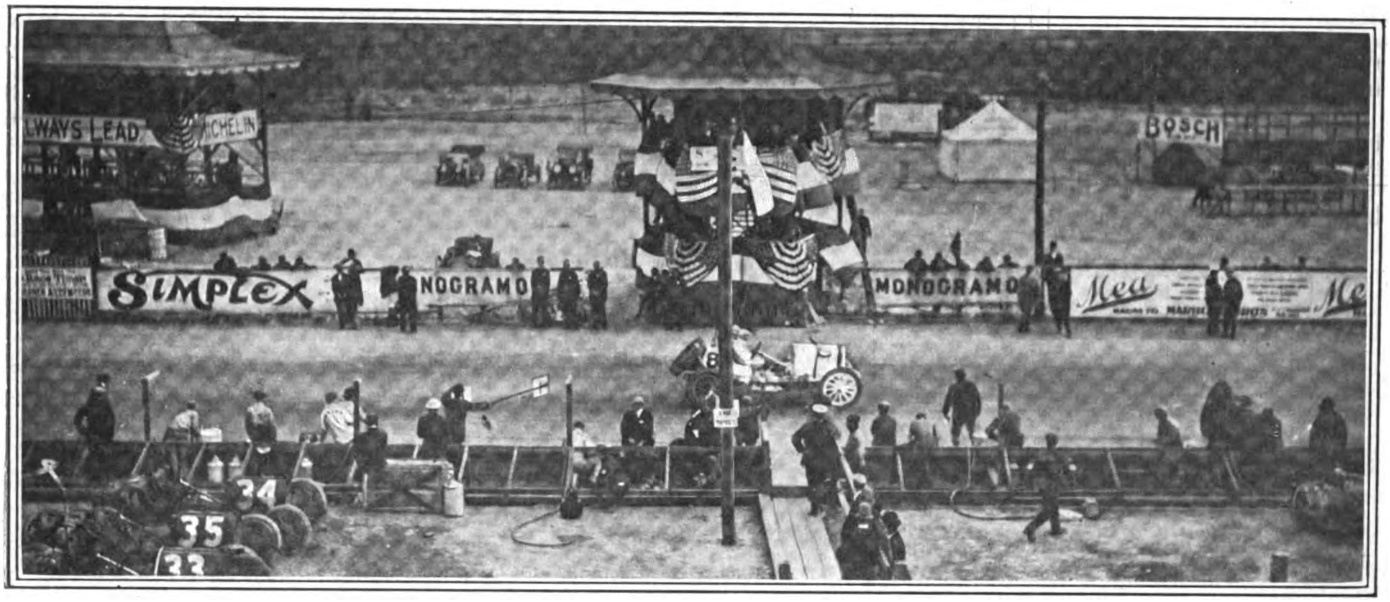
place which he held for a couple of circuits. He mounted to sixth in the sixth lap; went to fifth in the seventh; only to fall back to sixth in the eighth. In lap nine the dropping out of Patschke raised him one and he gained another due to the fortunes of tires in road racing, so that at the end of the circuit he was in fourth place. He remained fourth in laps nine and ten; was third in eleven and twelve; and was second in lap thirteen, being exactly 1 minute back of the flying Hearne in the Benz. But when almost within striking distance of first he stopped to change tires, made a slow lap in 15:52, Benz took the lead and Brown found himself in fifth place. Then he had to begin climbing all over again. But he kept steadily at it. By the end of lap fifteen he was back in third place having got in in advance of Bragg in the other Fiat, and also the Lozier. Lap sixteen saw him in second place with the Benz ahead; but he dropped to third in laps seventeen, eighteen and nineteen. Then at one fell swoop he jumped ahead of both Hearne and Mulford, and took first place. He held it for lap twenty-one, but Hearne was close on his heels, being only 36 seconds back of him and Mulford little more than a minute in the rear. Then came the fatal end of the twenty-second, when all three of them stopped. Fiat got away with an advantage of over a minute on the Benz and it was all over but the shouting, because Brown was first in the twenty-third lap and first in the twenty-fourth. Through



Looking across the track from the paddock. The pits are in the foreground and the timers' stand on the opposite side of the track

all of this changing, the like of which was never before seen in a road race in this country, Brown worked coolly along. He changed twelve tires from start to finish. He changed all of these at the pits, seven being changed at the tire repair station on the backstretch and five at the grandstand pits. In five of the stops he changed two tires at a time, both rear wheels and in the other two stops he changed one tire each. He did not make a tire change at any point along the course.

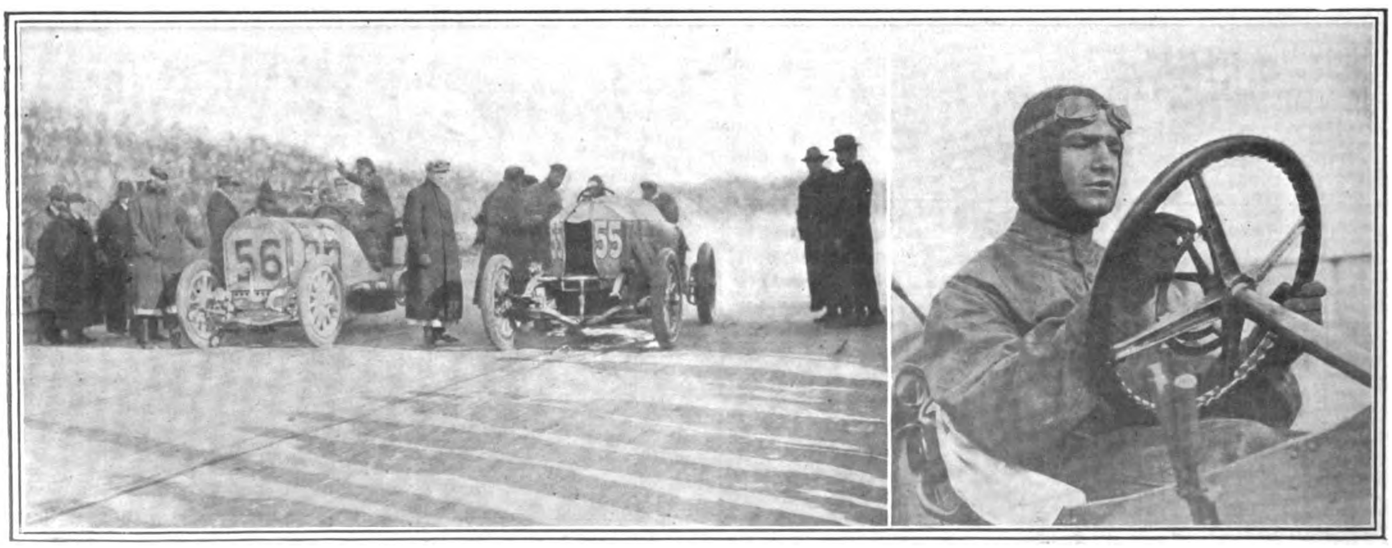
Most Thrilling Race in America

To-day's race was one of the most spectacular ever seen in America. There were sixteen cars that faced the tape and got away in good shape. Of these only five finished the twenty-four laps, but two more, the Abbott-Detroits, were running at the finish. Nine cars were compelled to give up the gruelling struggle. From the start to the end of the twenty-second lap the race might have been won by Brown in the Fiat, by Hearne in the Benz, by Mulford, in the Lozier, or by De Palma, in his Mercedes. At this point Hearne led, being 24 seconds ahead of Mulford and 42 seconds ahead of Brown; De Palma was over 3 minutes back. It required only a little unexpected tire trouble to make any one of the three a leader. Hearne had his in the second to the last lap and in the same lap Mulford was retired, leaving the course clear for Brown and his Fiat.

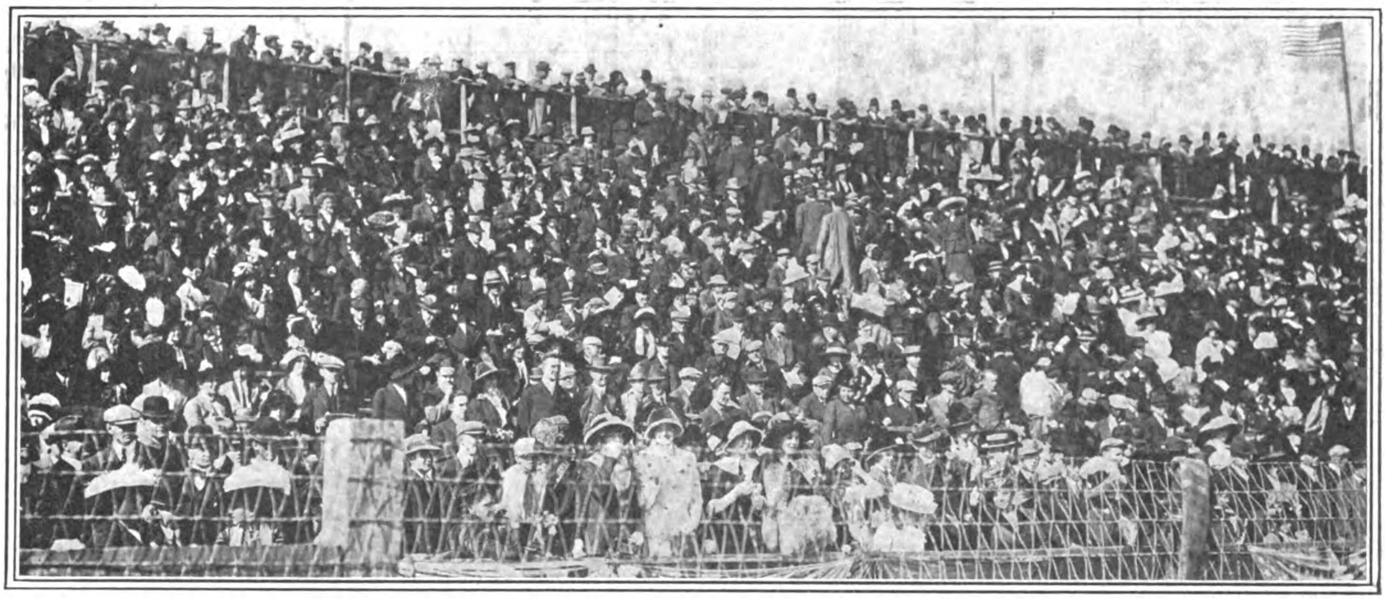
From start to finish the race was one of never-ending interest. The leadership changed no fewer than seven times in the twenty-four laps. Caleb Bragg, in a Fiat, a duplicate of the one Brown drove, led for the first three circuits, but fell behind De Palma in the fifth, due to tire troubles; De Palma held the lead for but a single circuit when it fell into the keeping of Eddie Hearne and his Benz who maintained it for laps five and six. Then he dropped it into the hands of Cyrus Patschke in his Marmon, who held it for laps seven and eight, when he dropped out of the race. From the start of the race Hearne had been making laps in 5 to 6 seconds under Patschke, so that as soon as tire troubles overtook him, Patschke was ready to grab the lead. When the Marmonite eliminated himself at the end of the eighth with engine troubles, Hearne was at hand, being only 9 seconds behind, and took the lead in the ninth with a margin of 1 minute over the Lozier and about the same on Wagner. Hearne held this lead until the twentieth lap, when for the first time, it fell into the hands of Bruce-Brown, who for the five previous laps had been steadily cutting down the lead Hearne had established earlier in the race. When Brown took the lead in lap twenty, he had only 31 seconds on Hearne, but he kept it and led in lap twenty-one by 36 seconds.

Lap twenty-two saw a change of leadership when Hearne by his dogged perseverance once again got into the front rank with a lead of 42 seconds on the Fiat, which lost its advantage, due to tire troubles.

Here, with only two laps to go, came the catastrophe. Brown, Hearne and Mulford all stopped at the pits. They were all there



De Palma's Mercedes and Hemery's Benz were the last away. De Palma ready for the word



The immense crowd at the grand stand included automobile enthusiasts of every section of the country

together. It was the most exciting moment ever witnessed in this or any other country in a road race. The Fiat was first into the pit to change tires. Not more than 3 or 4 seconds later came Mulford and then Hearne. Lozier took on gasoline only and was first away. Fiat second and Benz last. Everybody knew that the Fiat could make the fastest lap and so it did. It took first place in the twenty-third lap and held it for the twenty-fourth, winning by a margin of over 2 minutes. Many thought the Benz would have won if it had not stopped to change tires, but no one really knows. Hearne was fatigued from driving and would not take any chances in holding the car on the turns should a tire go. As it was Brown proved himself the same wonderful uphill fighter he was a year ago and Mulford and Hearne endeared themselves to every one by putting up the gamest fight that has been witnessed in a road race. De Palma, who finished third, was a strong favorite all day.

The elimination story was a particularly heavy one in that of the sixteen starters only five finished the twenty-four laps, and of these the Pope, driven by Disbrow was the only American car. Two other American cars were consistently running at this time, one being No. 44 Abbott-Detroit, piloted by Mitchell, and the other No. 50 Abbott-Detroit, driven by Limberg. Mitchell covered twenty-three laps of the circuit when he was flagged off and Limberg had negotiated twenty-one laps when he was called off, the race being declared over and the course thrown open. Had the two Abbotts been allowed to finish, which they undoubtedly would have done, it would have given America three cars at the finish as compared with four foreign machines that completed in the entire race.

Why the Cars Dropped Out

When it comes to the story of why the cars dropped out, attention is first drawn to the foreign ranks, as they were the first to be broken. Hemery was first in trouble, due directly to an exhaust valve giving away under the terrific speed. Undoubtedly the speed at which Wishart pushed his Mercedes was more or less responsible for the cracked cylinder, which caused his withdrawal. Bergdoll's trouble was not being able to shift from second speed. Wagner was eliminated by too fast driving on the curves and putting his steering-gear out of commission when he ran off the road. The other four foreign cars finished.

Five American cars were eliminated. First out was Cobe, in Buick, who upset on a curve. He was the first to give up the race. Second to drop out was the special Marmon car, driven by Burman. It stopped just before reaching the grandstand at the start of the fifth lap. The trouble consisted in the sprocket on the magneto shaft being destroyed. In lap 10 Patschke, driving the other Marmon withdrew, due to cylinders being loosened from the crankcase. He was leading when he pulled out. Basle, in a Buick, was next, dropping out in the following circuit. Mulford, in a Lozier as already stated, fell out in the start of the twenty-third lap, his trouble being the breaking of the main shaft

extension of the gearset. This shaft protrudes from the forward end of the gearbox and unites through a sliding joint and universal coupling with the clutch. Examination showed a slight flaw in this part, despite which the shaft proved sufficiently strong to carry the car to victory through the seventeen laps of the Vanderbilt Cup race and for twenty-two laps of the Grand Prize event.

Grand Prize in Detail

Lap 1—The foreign half of the racers set out to win everything in the first lap and when the end of the circuit was over, the eight foreign cars were in the van and the eight American cars in a group at the rear. The foreign eight averaged 77.3 miles an hour, as compared with an average of 68.7 miles an hour for the eight domestic cars, a difference of practically 9 miles an hour, a big handicap for the opening circuit. Bragg in his Fiat led the field by making the 17.14 miles from a standing start in 13:01, a speed of 79 miles an hour. But he was not alone, Brown in another Fiat averaged 78.4 miles an hour; De Palma in the Mercedes averaged 77.9; Hemery in a Benz 77.7; Wagner in a Fiat 77.6; Bergdoll in a Benz 75.4, and Wishart, Mercedes, 75.4. Hearne, Benz, who finished second in the race, was last of the foreigners in this lap with an average of 74.9 miles an hour. Mulford, who headed the American octette was close on the heels of Hearne, being but 2 seconds slower in the lap; Patschke with his Marmon was 12 seconds slower, and Burman in the other Marmon 16 seconds behind. Burman was just a minute slower than Bragg for the lap.

Thus did the first eleven racers complete the lap with only a minute's difference between the fastest and slowest. The remaining five cars were slower, as follows: Disbrow, Pope-Hummer, 14:55; Basle in Buick, 15:02; Cobe in Buick, 15:09; Limberg in Abbott-Detroit, 16:09, and Mitchell in Abbott-Detroit, 16:39, the last being at a pace of 61.7 miles per hour. There was a difference of 3 minutes 38 seconds between Bragg, the leader and Mitchell, the tail-ender.

Lap 2—The second circuit saw the eight foreigners still in a group at the front, with the eight American machines bunched in the rear. But there was only 1 second between Wishart, who was last in the foreign contingent, and Mulford's Lozier that was leading the home squadron. This was a Fiat lap, as they led in one, two, three fashion at this point, the order being Bragg, Brown and Wagner, with Victor Hemery, hope of the Benz camp, but 7 seconds behind Wagner, who was looked upon as the fastest of the Fiat trio. This lap saw several changes of position.

By making the lap in 13:09, a speed of 77.5 miles an hour, Hearne jumped from the last of the foreigners up two places, and Wagner, by sending his Fiat over the 17.14 miles in 12:58, 79.3 miles an hour, climbed past De Palma's Mercedes and Hemery's Benz, so the foreigners at the end of the lap stood Fiat, Benz and Mercedes. Mulford still headed the American cars. He made the circuit in 13:35, 75.6 miles an hour, his lap being 10 seconds faster than his first. Burman was second, having made the lap in 13:34, a second faster than Mulford, Patschke, dropped into third by a slower lap in 14:01. The positions of the other five American cars did not change, it being Disbrow, Pope; Basle, Buick; Cobe, Buick; Limberg, Abbott, and Mitchell, Abbott. There was at this point a difference of 6 minutes 32 seconds between the leader, Bragg, and Mitchell, who was bringing up the rear. Only two cars in this lap averaged over 80 miles per hour, these being the Bragg and Brown Fiats. Burman's Marmon was the fastest American car, doing the lap at

on Grand Prize Course

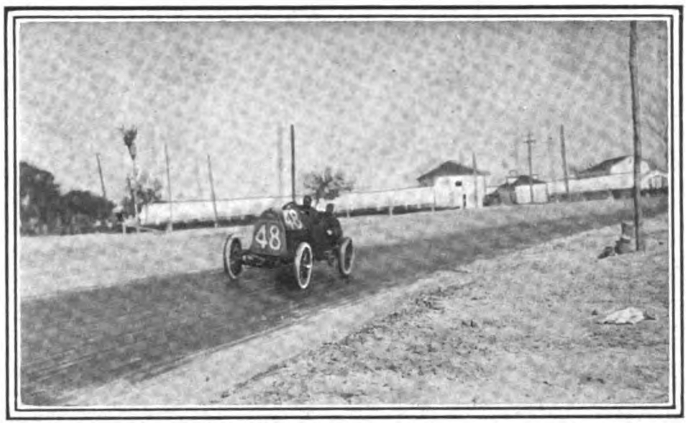
75.7 miles an hour with Mulford next, averaging 75.6 miles an hour.

Lap 3—This lap witnessed the breaking up of the united lead of the foreigners, Burman, Mulford and Patschke with their American cars having broken into the European phalanx, by getting ahead of Wagner's Fiat which had to stop at the grandstand pits for tires, they having passed Hemery's Benz that broke an exhaust valve and Wishart's Mercedes which had chain trouble. It was a case of five Europeans heading the race at this point, closely pursued by the three American cars, then Wagner's Fiat, next four Americans and last Hemery and Wishart, Cole's Buick went through the outer fence at the Montgomery cross road turn and upset. Fortunately nobody was hurt. This could not be looked upon in any other way than that of being a Fiat lap. Bragg and Brown were first and second, De Palma had his Mercedes in third almost a minute back of the Fiats and the two Benzes were fourth and fifth, Hearne and Bergdoll being the order. This lap was a distinctive gain for the home cars, Burman averaging 76.8 miles per hour. Both of the Marmons were faster than Mulford's Lozier, the times being: Burman, Marmon, 13:23; Patschke, Marmon, 13:26; Mulford, Lozier, 13:39.

The remaining four American cars were running more than a minute to the lap slower than these three so everyone looked to Burman, Patschke and Mulford to wage the bitter war against the Fiats, Benz and Mercedes racing machines. Nobody knew at this moment what would be the outcome. The enormous speed of the foreigners had started to show its results in two different ways, in tires, Wagner having to change both rears after but three laps, and in mechanical troubles, both Hemery and Wishart's machines not being equal to the enormous speed possibilities of the course. Would Bragg and Brown still be able to maintain the 79-mile-an-hour pace they were setting? If they could the American car would have but little chance. Not taking into consideration Wishart and Hemery, who were tail-enders, there was at the end of this lap a difference of 10 minutes between the leader Bragg and Mitchell, last of those actually running steadily.

Fiat Loses the Lead

Lap 4—This lap was a Fiat catastrophe. For the first time the Italians lost the leadership, De Palma's Mercedes gaining first place, with Hearne and Bergdoll in the two Benz machines second and third and Burman's Marmon fourth. An American car had jumped from eleventh to fourth place in four laps. The Fiats' downfall was due to tires. Bragg had to change and so had Brown. Brown's stop was a long one, making the lap time 19:39, by far the slowest one he had in the entire Grand Prize race. He dropped abruptly from second to eighth place, and many thought that his hopes for victory had gone with his tires. The race was becoming interesting, with an American car fourth and two others sixth and seventh. Everyone felt settled that the Fiats could not continue their 79 miles an hour without having to change tires every three or four laps, and as the driver and mechanic had to do all of the tire changing work, it was problematic if the slower cars such as Marmons, Lozier, Benz and Mercedes, with fewer tire changes, would not win out. Everybody took a new view of the race at this point. The honor of the fastest lap went to Eddie Hearne in his Benz, his time being 13:15, his fastest lap so far, and a speed of 77.9 miles per hour. Few knew what Hearne could do with his car. He started last of the foreign group, being slowest in the first circuit, but in four laps he jumped into second place and showed that he had a car as fast as the De Palma Mercedes. It might be said that at the end of this lap there were seven strugglers in the lead and all



The winning Fiat negotiating the turn from Waters avenue

Scene on the homestretch in the nineteenth lap, when Mulford's Lozier was within a few seconds of the lead

within 2 minutes of each other. De Palma, the first of the seven, had made the four laps in 53:08 and Wagner, the slowest, in 55:32. Brown's Fiat was not reckoned in this group as its time was 58:31, but a few seconds ahead of Basle's Buick and the Pope. In this lap Hemery limped past the grand stand and drew off to the side of the road to change a new exhaust valve. He was over an hour in making the third circuit and 47 minutes in the fourth, so that he was nearly 1 1-2 hours back of the leader and out of the race, excepting that he announced he was going to make a repair and go after the fastest lap. Wishart with his Mercedes was now 1-2 hour back of the leaders, and there was 11 minutes between the first and the last of the thirteen cars that were running steadily at this point.

Lap 5—This was an unfortunate lap for American representation as it saw Burman's Marmon drop out when it was running in fourth place and leading the American representation by a matter of 32 seconds over Mulford and Patschke who had tied in lap four at 54:56. When Burman fell out Mulford took up his scepter, having gained 4 seconds on his rival, Patschke, in the fifth circuit. The remainder of the Americans, namely, Buick, Pope and the two Abbotts, were running in this order, the same as from the opening lap. The home representation had now dropped from eight to six, with Mulford and Patschke to look after the fast Italian and German cars. The end of this lap saw Hearne in the lead, having got ahead of De Palma who had trouble with a leak in the gasoline line which compelled him to use an auxiliary gasoline line that he already had attached. Hearne now led with a margin of but 29 seconds over Bragg; and Mulford and Patschke were not 2 minutes behind. Then came Wagner, Bergdoll and Brown. Brown was 6 minutes back of Hearne. Hemery fulfilled his previous announcement of going after the fastest lap of the race and he won it, doing the circuit in 12:36 or a speed of 81.6 miles per hour, the fastest official lap ever made on the course. He drove with all his old-time fearlessness. He took all of the turns very fast. When he shot into the homestretch everybody saw by his tremendous speed that he was after the coveted mark. He was slow in shutting down for the grandstand curve and struck it at apparently 70 miles per hour. Entering the turn he held close to the inside, but the momentum of the car was too great to hold it and he skidded wide, almost to the upper side of the bank. He soon straightened up and roared past the grandstand. His skid was the only really bad one made by any of the big cars on the turn, and the hundreds in the grandstand who wanted to see such a performance were satisfied. Bragg sustained his previous reputation by making the second fastest lap in 12:58, the only other one to get under the 13-minute mark. His pace was 79.3 miles per hour.

Lap 6—There was a general changing of positions in this lap, Hearne retaining the lead, but being about the only one of the leaders to hold his place. He had a lead of only 50 seconds on De Palma and but little over a minute on Patschke, Mulford and Wagner. The two Fiat drivers, Wagner and Brown, were closing the gap between them and Hearne, both doing the lap in several seconds under Hearne. Patschke and Mulford were third and fifth, disputing every inch of the course with De Palma and Wagner who was running a little slower than in the early laps and apparently taking more care of his tires. Brown made the lap in 8 seconds less than Hearne, but Wagner had the fastest circuit of the lap in 13:00, 79.1 miles per hour.

Marmon Takes the Lead

Laps 7 and 8—These were the brilliant laps for the American contenders, because Cyrus Patschke put his Marmon racer to the front and led the entire field—the only two laps in which the American colors led—but unfortunately the pace he set was apparently too strenuous, for he withdrew in the ninth lap, leaving Mulford to do the fighting single-handed against the five foreigner drivers who along with Mulford were making the race at this time. At this point Bruce-Brown was not very much in the limelight. He was still back in sixth place, not having recovered from that terrible setback in the fourth lap. But he was slowly coming out of the darkness, doing laps in 30 to 40 seconds lower than Mulford and Hearne. The seventh was a bad lap for Hearne. He had tire troubles, made a slow lap in 15:14, but hung onto second place by 7 seconds over Mulford and Bragg, who were tied for third place. At this point the positions were: Patschke, Marmon, 94:55; Hearne, Benz, 95:30; Mulford, Lozier, 95:37; Bragg, Fiat, 95:37; Wagner, Fiat, 96:42; Brown, Fiat, 98:38; De Palma, Mercedes, 99:29.

These were the fighting seven, the other seven trailing along far behind and practically out of the race. De Palma had fallen from second place in the sixth to sixth place in the seventl due to his gasoline lead. This advanced all of the other racers one place. The first four were not separated by a minute at the end of lap seven or 120 miles, good proof of the desperate struggle that was taking place. Lap eight was a duplicate of lap seven, excepting that Wagner climbed above his team mate Bragg by a lap in 12:55 or 79.6 miles per hour. This lap marked the start of Bragg's bad luck. An oil lead at the forward end of the motor broke, due to the vibration. It was a hard place in which to make a repair and he blistered his hands in doing the work. He also had to make a tire change on the course and stopped at the grandstand to take on a new shoe. Brown gained from 9 to 10 seconds on Mulford and Hearne in the circuit.

Hemery finally withdrew at the end of the eighth circuit with valve trouble. Wishart also withdrew his Mercedes, due to a cracked waterjacket.

Lap 9—The field was now down to ten machines, five American and five foreign contenders with the race not half over. Of these ten, the first six were making the race, the order at the end of this lap being Hearne, Wagner, Mulford, Bragg, Brown and De Palma with only 4.5 minutes between the first and the last. The three Fiats made the fastest laps, 12:48, 12:53 and 13:03. They were 1-2 minute faster than any of the others in the lap and so everybody wondered if the Fiat colors would again come into the lead, they having been in the background since the third lap.

Lap 10—Hearne increased his lead on Wagner who stopped for oil and gasoline and also changed tires, making his lap a slow one, 14:31, as compared with 13:20 by Hearne. But Brown, though down in fourth place, was traveling fast. He reeled the lap off in 12:48, over 80 miles an hour, and was scarcely 2 minutes behind the leader at this point. He was steadily gaining. De Palma stopped 3 minutes and 30 seconds for gasoline and oil as well as to change a right rear tire and so found himself dropped from third to fifth place. Basle, who had been running in seventh place, dropped out due to engine troubles.

Looked Like Hearne Victory

Laps 11 and 12—Lap eleven saw Hearne running steadily in the lead with Fiats second and third and 4 minutes behind him, Wagner and Brown being the chasers. De Palma and Mulford were close up but Bragg was 10 minutes in the background. In lap twelve the positions were the same as in lap eleven, this being about the only case of two successive laps in the race in which positions did not change, with the exception of lap twenty-four, in which they were the same as in lap twenty-three. Hearne's time was the fastest in lap eleven, it being 13:22. Hearne led in lap twelve, but stopped 2 minutes 35 seconds for gasoline and oil and tires. Wagner and Bragg made the fastest circuits, doing close to 80 miles an hour. There was now an interval of 36 minutes between the leader Hearne and Mitchell's Abbott. Through all of these laps the Pope-Hummer, piloted by Disbrow, and the two Abbott-Detroits were showing their dogged consistency, going lap after lap at a steady pace. Disbrow was making nearly all of his circuits in 14:38, and the two Abbott-Detroits about a minute to the lap slower. With the race half over Hearne had a lead of 3 minutes on Wagner's Fiat and 4 minutes on Brown's Fiat. He was 5 minutes ahead of De Palma in the Mercedes and 5.5 minutes lead on Mulford. He seemed to be in a safe position, excepting that it was known the Fiats could make faster laps than he, and if he had good fortune and the Fiats met with tire troubles he would certainly win.

Lap 13—It was in the start of this lap that Hearne had stopped for fuel and made a very slow lap, 16:16. Brown put his Fiat around the circuit in 13:12 and so cut off 3 minutes of the 4-minute lead Hearne had enjoyed. The five leaders, Hearne, Brown, Wagner, De Palma and Mulford, now were more closely bunched than at any other time since the start. It was proving a wonderful race. Hearne was just a minute ahead of Brown. Brown was only 21 seconds ahead of his team mate, Wagner, De Palma was but a minute back and Mulford 1-2 minute behind De Palma. It was now anybody's race. These battlers were almost 20 minutes ahead of the Pope and the Abbotts. Brown was now second and only a minute from leadership. All expected him to cut that minute off in the next lap and take the lead from Hearne who had held it for five successive laps.

Lap 14—The unexpected happened. Instead of taking the lead from Hearne, Brown stopped for tires, was stopped 1 minute 20 seconds at the pit and found himself fifth or last in the bunch of leaders. Never before was there such a five-sided duel. It meant but a tire change to alter the entire state of affairs. A mere stop of less than 2 minutes made the first last and the last first. Wagner was the hero of the lap, making the circuit in 12:48 at a speed of 80.3 miles an hour. It put him in second place, only 24 seconds back of Hearne. He now was looked upon as the leader in the following lap. De Palma and Mulford were 2 minutes back of Wagner and Brown a minute behind them.

Lap 15—This lap was unlucky for the Fiats as Wagner was eliminated. His 80-mile pace of the previous lap was too much. He tried to duplicate in this circuit but overran a turn. Nobody knows exactly what did happen. But the rear axle was a little sprung and the steering out of commission. He drove to the grandstand and withdrew. This left but four leaders in the real fight, as Bragg was 12 minutes behind the group and he was in turn 10 minutes up on the Pope and 20 and 25 minutes on the Abbott. There were yet nine laps to go and the leaders stood in this order: Hearne, Benz, 206:57; De Palma, Mercedes, 208:00; Mulford, Lozier, 208:28; Brown, Fiat, 208:31. There was not 2 minutes between the first and the last.

Lap 16—This lap worked an upheaval; Brown passed both Mulford and De Palma and got in second place just 1 minute 25 seconds back of Hearne, almost as close to him as he had been three laps before. Brown was driving conservatively. For the last five laps he was making circuits in 13:12 or thereabouts, which averaged 30 seconds to the lap better than Hearne and apparently he had settled down to get into the lead by this kind of driving rather than by the terrific speeds that put Wagner out

Hearne's Benz passing Limberg's Abbott-Detroit on the wide curve leading from the Waters road and also caused the oiling troubles on Bragg's Fiat. It was now really a single-handed fight among the Benz, Fiat, Lozier and Mercedes. Mulford, who started single-handed, was still in the ring; De Palma had lost his running mate in the ninth lap and both of Hearne's supporters were gone. It was now a real fight, and with the Fiat cutting the frills out the race was taking on a new aspect. It was real business and not sensationalism.

Lap 17—The great fight in this lap was between Hearne and Mulford, Hearne having the lead by only 27 seconds. Brown met with tire troubles and went slowly in 15:26, practically 2 minutes slower than the other three. Bragg was now running in fine shape but 15 minutes behind this group.

Laps 18 and 19—These two laps were races, the order being Hearne in the Benz, Mulford in the Lozier, Brown in the Fiat and De Palma in the Mercedes. Brown made each of these laps in 30 seconds under the other drivers and so found himself at the end of lap nineteen but 43 seconds from first place, the closest he had been from the start of the race. Hearne still led with Mulford second. This was the standing: Hearne, Benz, 263:03; Mulford, Lozier, 263.18; Brown, Fiat, 263:46; De Palma, Mercedes, 267.25. De Palma had lost his time on changing tires.

Lap 20—Brown leads. This was shouted everywhere, and for the first time the winner of the Grand Prize last year was able to put the Fiat colors to the front since the third lap when Bragg had placed them there. Yes, Brown led and led with but four laps to go. But his lead was only 14 seconds on Mulford and 31 seconds on Hearne. Brown gained his place by fast traveling, doing the circuit in 13:18, as compared with 14:00 by Mulford and 14:32 by Hearne.

Lap 21—The struggle continued, Brown increased his lead from 14 seconds to 36 seconds over Hearne and was over a minute ahead of Mulford. De Palma was 4 minutes back.

Lap 22—The end of this lap saw the most intense moment ever witnessed in a road race. It saw all three racers, Brown's Fiat, Hearne's Benz and Mulford's Lozier, stop at the pits together and with but two more laps to go. A driver will not stop at such an important time unless there is a reason. Brown was first into the stretch in sight of the grandstand. He was cheered to the echo. He slowed into the turn. "He is stopping" was heard on every hand. Back of him raced Mulford. He slowed also and stopped. The entire grandstand was on its feet. Scarcely was he at the pits than Hearne rounded the turn and stopped. Brown was 1 minute and 8 seconds changing a left rear tire; Mulford was 36 seconds taking on some gasoline, and Hearne was 1 minute changing a right rear tire. Many at the Lozier pit did not want Mulford to stop, but he had been signalled the previous lap to stop for fuel and did not take any chances. Many in the Benz pit thought Hearne should not have stopped, but it seems that he was fatigued from the long grind and would not take any chances with a poor tire on the turns. Mulford was first away. He dropped into second and shot off. Brown was hot after him and Hearne was last. According to the official figures, Hearne led for the lap. His time was 304:42; Mulford's time was 305:08, and Brown's 305:24. Brown was last, which was due to the fact that he did not cross the tape before repairing his tire whereas Hearne and Mulford did.

Laps 23 and 24—These were fatal to American interests. Scarcely had Mulford started on lap twenty-three when he went out of the running by twisting the clutch off the outer end of the axle-drive shaft. In taking a street-crossing the car bounded into the air and when the back wheel struck the ground the engine speed up and the car slowed down. Mulford knew the trouble and pulled to the side of the road. The remainder was a procession. Brown was leading. At the end of the twenty-third lap when he got the green flag he was 1 minute 30 seconds ahead of Hearne. Nothing but tires could stop him. The lap was a fast one, too, the time being 12:53 or nearly 80 miles per hour. De Palma was 3 minutes behind. In the last or twenty-fourth lap, Brown slowed down to 13:12, still 1-2 minute faster than Hearne, but only a couple of seconds faster than De Palma made the circuit. At this time Brown was laps ahead of the Pope and the two Abbott-Detroits. He was 50 minutes ahead of Disbrow and an hour ahead of the leading Abbott, all of which were lower-powered cars.

KlineKars Win Handily at York

YORK, PA, Dec. 1—KlineKars finished as winners yesterday afternoon in five of the seven events in which they were entered in the meet of the South Jersey Motor Club, on the York fair ground track. The track record for five miles was twice broken and a new record for one mile established. About 1,000 persons witnessed the races.

The first track record was broken in the third event, when the five-mile time was lowered by a KlineKar to 6:46 3-4 from 7:07. The best mile of the five was made in 1:24. The same car driven by Menker in the special handicap again established a new record, doing the five miles in 6:25 1-4.

Four events were omitted from the program, which originally included ten. These were the special handicaps for winners and losers, the time trials and the second heat of the division 20 class. For the time trials there was substituted a special handicap race between an Abbott-Detroit car driven by Padula and a Mercer driven by Ringler.

The event between Padula and Ringler provided a fast and exciting race. Ringler had his opponents' handicap of 20 seconds well made up by the sixth heat, but waited for the last mile before going in to win. Then, at full speed and taking the turns in a faultless manner, he closed up on the Abbott racer and beat Padula to the tape. The summary:

Car	Driver	Position	Time
5-mile Non-Stock			
KlineKar	Menker	1	7:37¾
Abbott-Detroit	Padula	2	......
Buick	Haupt	3	......
5-mile Non-Stock

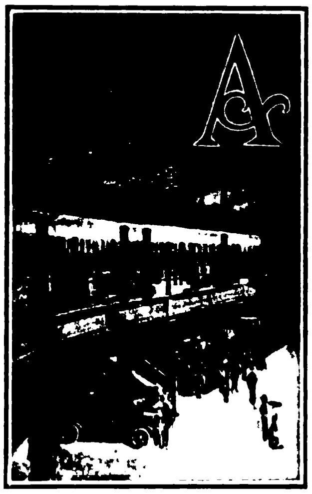
Loziers Are Shaft-Driven Cars

In last week's issue of THE AUTOMOBILE, in the story of the Vanderbilt race, the statement was made that "the Loziers are chain-driven machines," etc. Of course every well-posted automobilist knows that the car that won the Vanderbilt is shaft-driven. The car to which the writer had reference was the Mercedes, but through an unaccountable error the name Lozier was substituted.

News of Shows, National and Local



REVELATION in the decorating of automobile shows is promised at the twelfth national automobile show in Madison Square Garden, January 6 to 20. For several months past those in charge of the show have busied themselves producing a proper setting for the motor cars, motorcycles and accessories and no expense is to be spared to make the setting the most attractive ever seen in the historic building. Not only in the matter of decoration but in every other detail is the show committee striving to eclipse all former exhibitions. As this is to be the last automobile show to be held in the Garden, old patrons are assured of witnessing a spectacle which is bound to be lasting in their memory. As usual, the full description of the decorative scheme has been withheld by the show committee because of minor changes but it will soon be released. The Garden interior this year will be richer and more magnificent than for any previous affair, although perhaps more refined in treatment.

Partial M. & A. M. Show Program

Announcement has been made of a partial program for the Motor and Accessory Manufacturers during the approaching show season in New York. The annual meeting will be held at the Waldorf-Astoria, commencing January 10 at 10:30 a. m. The feature of this meeting will be the election of four directors. There is no well defined policy of succession in office in the M. A. M. and consequently the personnel of the official roster is uncertain.

The annual banquet, reputed to be one of the most elaborate of the metropolitan show season will be held at the Waldorf-Astoria, January 11, at 7 o'clock.

In addition to the big showing of the members of the association at the Madison Square Garden exhibition, it has been announced that twenty-eight of the members will show at Grand Central Palace.

The following new entries have been received by the Motor & Accessory Manufacturers, for the exhibitions arranged by the management:

For Madison Square Garden, for both weeks: Warner Instrument Co., Beloit, Wis.; first week only: Detroit Electric Appliance Co., Detroit, Mich.; Noera Manufacturing Co., Waterbury, Conn.

For Chicago show, both weeks: R. E. Hardey Co., Chicago, Ill.; Texas Co., New York City; U. S. Tire Co., New York City; first week only: Chicago Telephone & Supply o., Chicago, Ill.; W. F. Spocke Machine Co., Indianapolis, Ind.; Standard Thermometer Co., Boston, Mass.; Hess Springs & Axle Co., Carthage, Ohio.

Denver Space Almost All Gone

DENVER, Dec. 4—Definite arrangements for the annual Denver automobile show have been completed and under the auspices of *Motor Field* of this city the big event will be held at the Auditorium March 4 to 9. Already 14,500 of the 15,100 available feet of floor space has been assigned and it is expected that within the next week the allotments will be exhausted. Lively interest is being shown in the enterprise by the local dealers and it is expected that the Spring trade will show a decided advance over the slack fall business as a result of the attractive displays which will be made.

An effort toward building up the motor truck trade in Colorado will be made. One day will be designated as Motor Truck Day and rural dealers who have territory that is considered especially open to truck sales will be invited as guests of the management.

Importers Draw for Salon Space

Drawings for space at the coming show of the importers was held yesterday afternoon at the Hotel Astor. The show will open January 2 in the banquet hall of the hotel, occupying the same quarters as last year. Among the cars to be exhibited are the following: Renault, Itala, Isotta, Minerva, Opel, Benz, C. G. V., Darracq, DeDion, Napier, Picric, S. P. A., Metallurgique, Lancia and Mercedes.

Other Shows in Prospect

TOLEDO, O., Dec. 4—Toledo will have an automobile show this winter according to the plans which were definitely evolved this week. The show will be given under the direction of the Toledo Automobile Dealers' Association, January 15 to 20 inclusive and will be held in the large terminal railway building on Cherry street. It has been determined that the entire management of the exposition shall be placed in charge of Hugo V. Buelow, of Detroit, an expert in this line of work. The entire ceiling of the exhibition building will be of trellis, the walls will be covered with light blue bunting with a heavy flounce of old gold color. A carload of Southern smilax has been ordered from Alabama, 20,000 artificial roses will be made up, a large number of paintings to adorn the walls, statuary costing $5,000 and 10,000 incandescent lights will add to the beauty of the structure.

DAVENPORT, IA., Dec. 4—The directors of the Davenport Automobile Association have set the date for the annual automobile show on Feb. 28-March 2, which places the local exhibit between the St. Louis and Des Moines shows and thus enables dealers to arrange for exhibits at all three. This year the show date does not conflict with the Chicago Truck Show as it did last year. Half of the display this season will be trucks.

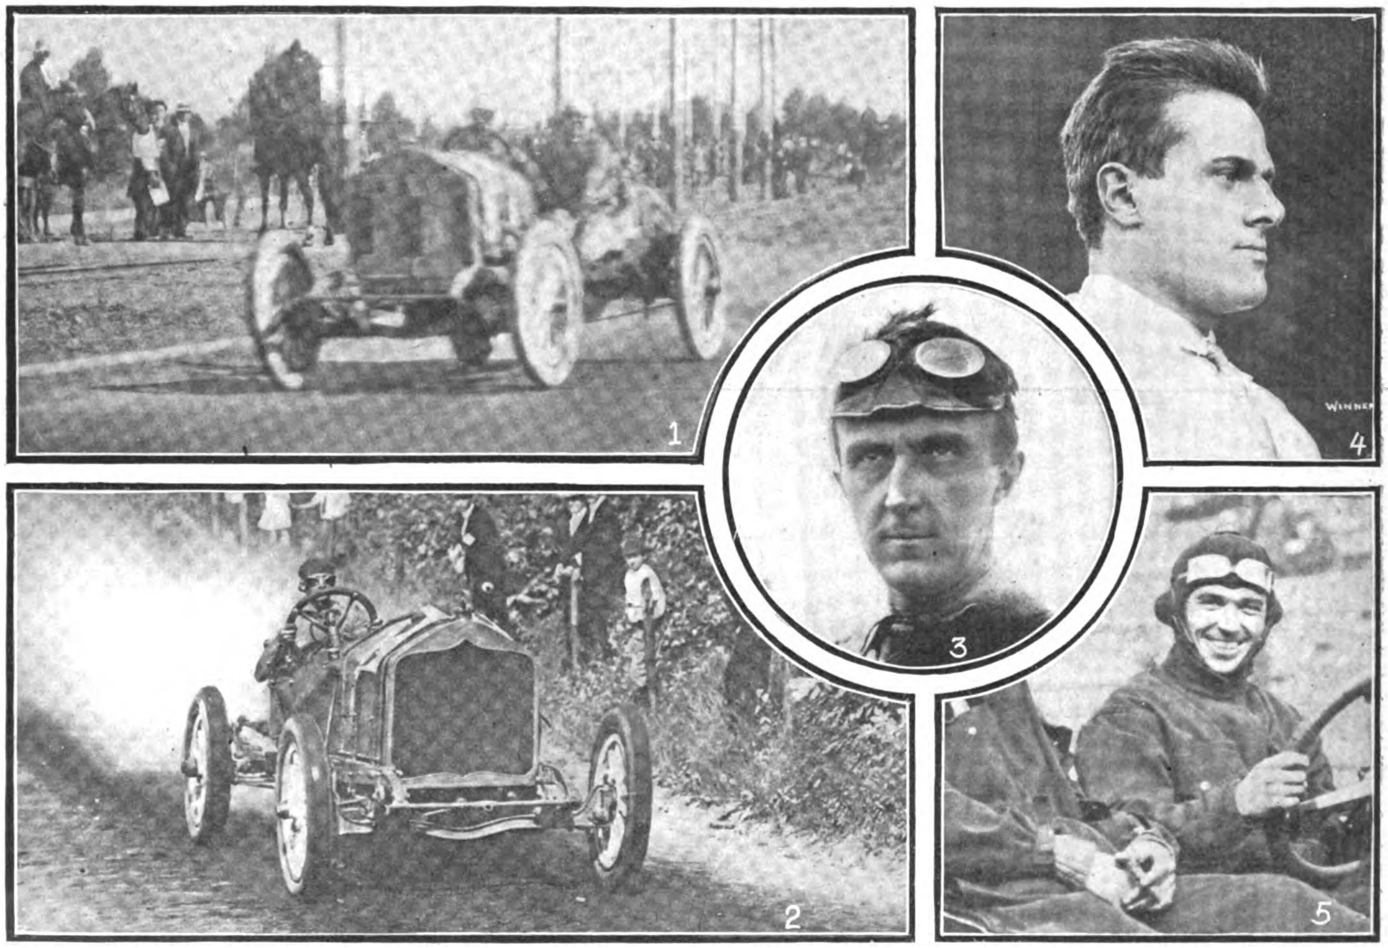
ROCHESTER, N. Y., Dec. 4—The Rochester Automobile Dealers' Association will hold its annual automobile show the week of January 22-27 in the State Armory. Pleasure cars, commercial vehicles and accessories will be shown. Great interest is being manifested by the public as well as by the dealers and a most successful exhibition is expected.

DETROIT, MICH., Dec. 4—At the second and final drawing for space for the 1912 Detroit automobile show, held in the offices of the Detroit Automobile Dealers' Association last week, the remaining 4,000 square feet of floor space was distributed among 13 independent concerns as follows: Oakland Motor Car Co., Anderson Carriage Co., Krit Motor Car Co., the Marquette Co., the Motor Wagon Co., W. A. Patterson, of Flint, Mich., the Hupp Corporation, Flanders Manufacturing Co., Commerce Motor Car Co., C. S. Briggs, showing his new "Detroiter," the Churchfield Motor Co., of Sibley, Mich.; the Miller Car Co. and the Grinnell Electric Co. An unusually elaborate decorative scheme is being worked out. The work will be performed by one of the largest decorating concerns in the United States.

Résumé of the 1911 Racing Season

NEW racing records were made in all departments of contest work in the automobile season of 1911. On beach, track, road, hill and speedway the flyers traveled faster than they ever had before. A new set of world speed marks was established in several of the classes.

The season of 1911 proves that the art of manufacturing automobiles is more perfect than it has been in the past, and the proof may be briefly cited from the single fact that the wonderful time made by a Fiat car over the 30-mile Florio road course in Italy several years ago was beaten this year by one or two American-made cars, approximately stock models, over shorter circuits.



1—Herrick in the National, making new American road record at Santa Monica. 2—Wilcox in the National, breaking the record in the Dead Horse hill climb. 3—Ray Harroun, speedway champion of the world. 4—David Bruce-Brown, winner of the Grand Prize. 5—Witt, who created new 161-230 and under-160 records with E-M-F and Flanders.

On the speedways of Indianapolis and Los Angeles some remarkable performances were accomplished.

Dirt-track racing, while much less popular than before, showed decided progress in speed, while on the hills the general average of performance was much better than in 1910. Beach racing also demonstrated its value as never before.

The features of the 1911 season were the road races for stock cars and special racing machines. The stock cars only performed as such in one big meeting, while the special cars showed their paces in six major events.

Hairline finishes that marked the running of most of the big races in 1910 were absent this season. In 1910 the Fairmount Park, Vanderbilt Cup and Grand Prize were won by seconds and mighty few of them. This season the winning cars have had more margin, but in no case except the Fairmount Park race was the victory what may be termed hollow. Even then only about 3 minutes separated the first two cars.

The season has been strange from the rising of the curtain until its final drop. Starting off with the promise of an organized racing circuit to insure good fields and skilled administration for the speed events to be held in all the racing centers, the program flattened out and for a while it seemed that the knell of racing had been rung. The grand circuit idea found no favor with the manufacturers and under the circumstances it is remarkable that the Indianapolis race held May 30 proved to be such a popular event.

This race was the longest and hardest contest for automobiles ever staged on a special speedway. It attracted the largest and most varied field of entries that ever faced a starter and the largest paid attendance in the history of the sport. It was a marvelous race won by a six-cylinder Marmon car accurately handled by Harroun in his only major start of the year, assisted by Patschke with some great speed work.

The world's speed record in a road race was established October 14 in the annual Santa Monica road race at Los Angeles, when a National car driven by Herrick averaged 74.628 miles in an hour for 202.08 miles. The record made by the National in this event stands as the official mark for a completed race, but the time made by the car for 202 miles has been exceeded twice. The Lozier car in winning the Vanderbilt Cup averaged a fraction more per hour and the Benz car that finished second in the Grand Prize made 76.2 miles an hour for twelve laps. But these marks are at best intermediate records and as the figures show the rate of speed made over the shorter distance was not maintained

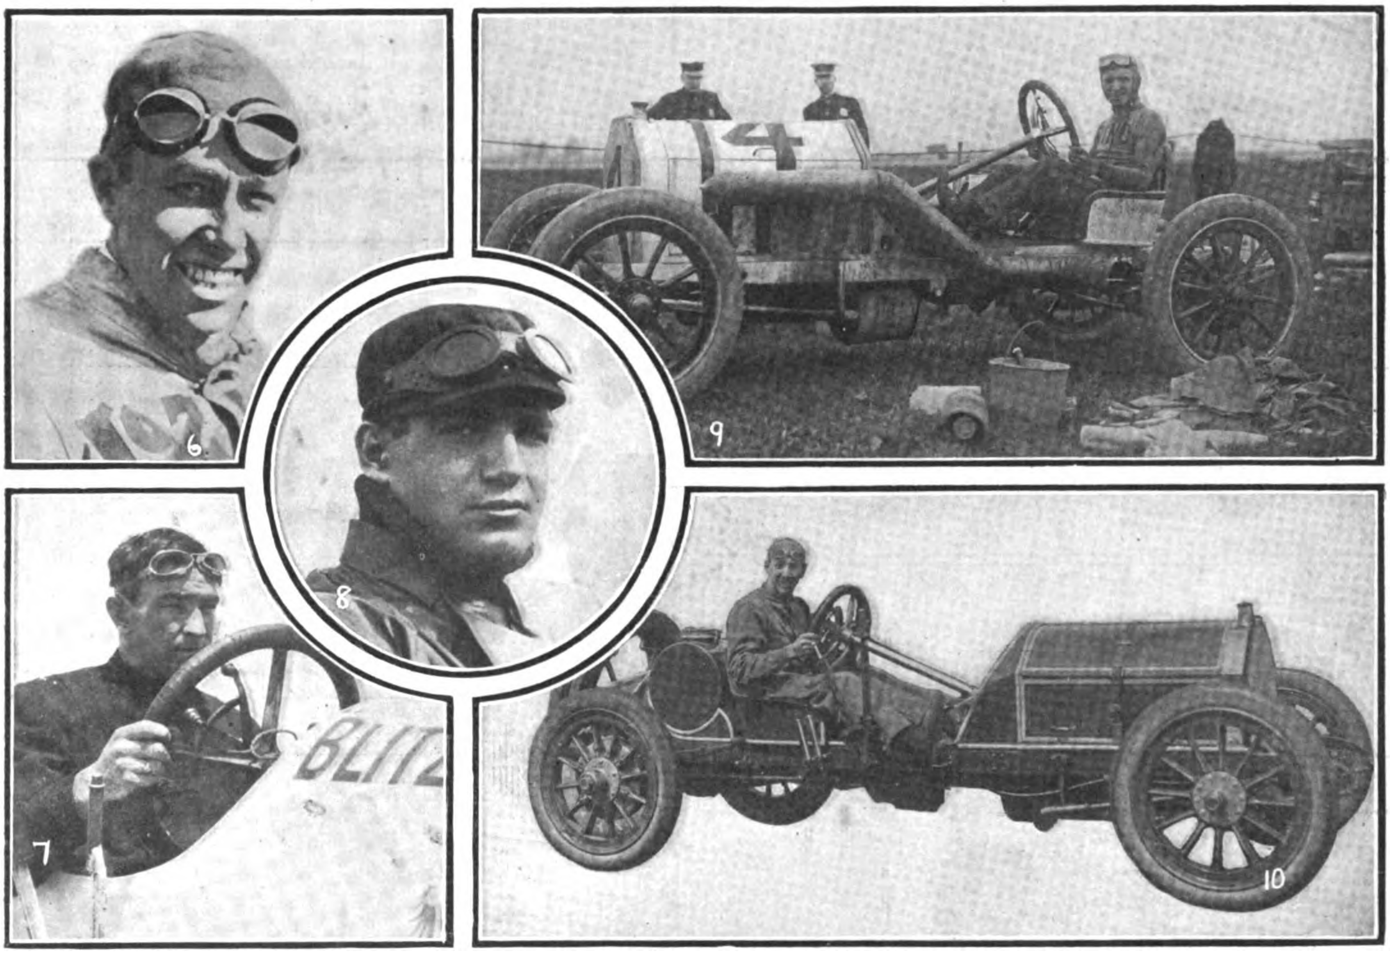
The Fairmount Park race is always much slower than any of the other big events because of the numerous dangerous curves and grades, but in this year's running of the event the course record was broken by a Benz car driven by Erwin Bergdoll. The new mark set is 61.149 miles an hour, almost 13 1-2 miles an hour slower than the record performance of the National at Santa Monica. This race was run in four classes, each being considered a race in itself.

The Elgin national stock car races proved victories for the

These were divided under five heads: Track, hill-climbs, road races, speedway events and beach races. There were 207 races run on circular dirt tracks at various points in the country, but largely centered in the district near New York City.

The tabulation under this head shows that the Simplex won more dirt track races than any other make of automobile. The figures might be somewhat confusing unless it is remembered that Ralph De Palma campaigned a powerful Simplex car most of the past season, winning race after race with it against small fields. This should not detract from the performance of the car, but due weight should be given to the fact that the showing of the Simplex on the dirt tracks was to a considerable extent based upon the work of one car.

The Mercer is second in this table with 20 winning races. Hughes, the factory driver, raced Mercers at track meets with much success, but the high standing of the car in the list is due



6—Ralph Mulford, this year's Vanderbilt winner. 7—Bob Burman, who drove the Benz and Opel to new records. 8—Ralph De Palma, competition champion of the year. 9—J. R. Rainey in the Cino, a winning combination. 10—Hughie Hughes, who drove the Mercer to many victories on track and road.

National in the two large classes and the Mercer and Abbott-Detroit in the smaller divisions.

But the climax of the season was the meeting at Savannah, where four great contests were decided. The winning Fiat, Lozier, Mercer and E-M-F established new marks in their various divisions. The performance of each was of the highest character. The Vanderbilt Cup winner closely approached and the victor in the Grand Prize race went faster than the old Florio record, while the showing of the smaller cars was much better than the existing records, for their classes and the distances run up to the time of the running of the races.

All told during the season of 1911 there were 361 contests decided of a major character. These were all duly sanctioned and officially administered. Of course there were more races run that were important locally and sanctioned, but in the following tabulation only the more important events are considered.

not only to the winning races in which Hughes drove, for Harvey Ringler, of Philadelphia, also contributed several wins to the total. The National and Cino are tied for third place in the standing with 18 victories each. The Cino victories were largely scored around Cincinnati, but Nationals raced all over.

The Benz, Buick, E-M-F, Case, Velie, Abbott, Staver, Inter-State and Opel made creditable showings. The latter was returned winner in five races along toward the close of the season and proved to be one of the speed sensations of the racing season.

One of the saddest angles in track racing is the showing made by a number of heaps of junk that masqueraded under the names of various well-known factories. For instance, a Peerless of 1906 was raced against other cars of current model; a Marmon that had once been a flyer, but which had outlived its usefulness, made a pitiful showing against cars that would have been easy for it in another day. Numerous other factories that take no interest in racing were pained to learn in the press that old cars bearing their names had finished out of the money and behind cars that would have proved easy for current models.

In hill-climbing there were 71 races run of sufficient importance to tabulate. The National cars won 23 firsts, most of the victories being scored by the factory team, although a few private owners and district agents added to the total. The Ford and Buick tied for second with the Oakland and Knox next in order. As a general proposition the time made over the various hills negotiated was better than it was in 1910.

There were 25 road races during the season, counting as races

Ideal hill-climb scene—stock car event at Algonquin

the performances of the various divisions of Classes B and C. The National won eight firsts, Mercer four, Fiat, Lozier and Buick two each and the remainder were divided among seven different makes.

On the speedways the National also led with five victories, but was closely pressed by the Simplex. The performance of the Marmon at Indianapolis was the most notable feat of the year on the speedways, but the Fiat made a wonderful showing in the 24-hour race run at Los Angeles where it turned 1,491 miles. On the beaches the National won 17 times.

Grouping all the contests it is found that the National leads by an overwhelming number of victories, scoring 72 wins during the season. In total number of victories this make stands first in each division except dirt track racing. The nearest competitors of the blue cars were the Mercers and Simplexes, with 30 wins each.

Buick, Ford, Cino, Benz and E-M-F are next in line and then follow the remainder of the 52 makes that took part in the racing of the year to the extent of at least one first.

How the Cars Performed

There were seven makes of foreign cars in American racing in 1911. These were Benz, Fiat, Opel, Mercedes, S. P. O., Hotchkiss and Lancia. The latter concern was represented by a single old car which failed to gain any appreciable laurels. The first three named raced the best product of their factories and there were two Mercedes cars in American contest work that would rank high anywhere.

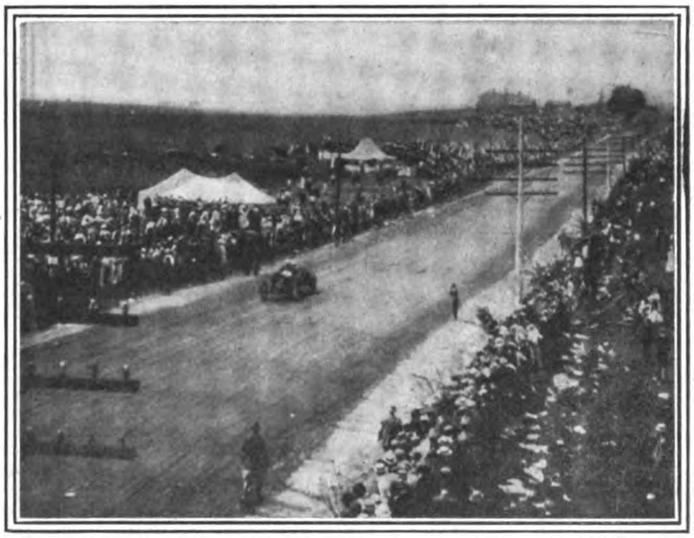
Coming down to the drivers, the tabulation shows that Ralph De Palma won 32 events, leading Burman by 10 victories. De Palma drove Simplex, Mercer, Fiat and Mercedes cars, winning mostly on a Simplex driven on dirt tracks.

Burman drove Benz, Opel, Mercedes and Marmon cars, scoring most often with the first named. In Wilcox, Zengel, Merz, Herr and Herrick the National factory was well off for pilots, as shown in the winning tabulation. In Disbrow and Dingley the Pope factory was well represented. The Mercer victories were scored by Hughes and Harvey Ringler. Kulick scored much success and Tower, of the Studebaker team, won many times with the E-M-F and Warren. Howard Bauer, of the Oakland company, had a high percentage of wins in a small number of starts. His performances were mostly hill climbs, at which form of contest he is regarded as being a leader. His specialty, however, is driving in endurance and reliability runs. Raimey, driver of the Cino, made an excellent showing in the winning column.

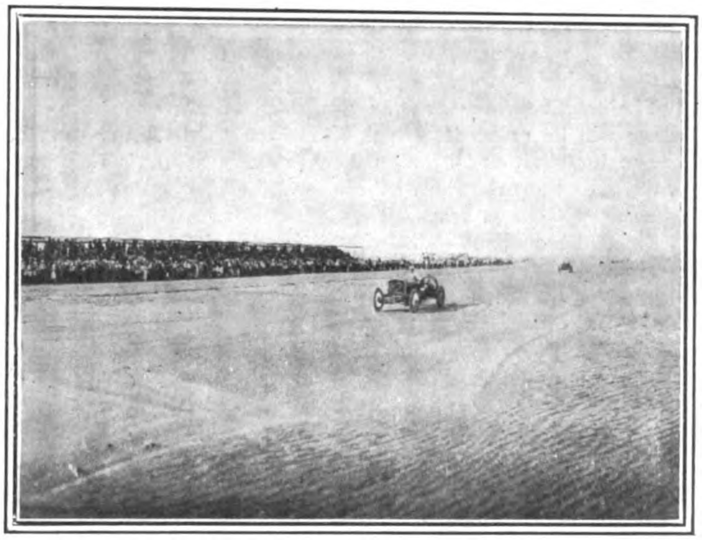
Bruce-Brown, winner of the Grand Prize, only started a few times during the year, but his work showed that he had forgotten nothing of his knowledge of driving. Harroun only started in one real race, the 500-mile international sweepstakes at Indianapolis, and won it. Mulford also was an infrequent starter, but he won his class in the Fairmount Park race, finishing second to the Bergdoll Benz. He also won the Vanderbilt Cup race.

Frank Witt, who drove the winning E-M-F in the Tiedeman Trophy race, made only a few starts during 1911, and the same may be said for such sterling performers as Belcher, Knipper, Hearne and Bergdoll.

Characteristic American Racing Scenes



The Elgin course during the National Stock Car Championships



Galveston's beach racing course during the spring meet

The factory campaign of the National company and the activity of De Palma, Hughes and Raimey in minor events, which count in the totals with the same force as the winning of a big road race, have served to confuse the perspective. On the figures the National is the champion of the year and De Palma is the kingpin driver. Burman is second in the list.

The tendency as shown in 1911 is toward centralization, but on different lines from those suggested by the futile grand circuit fiasco. A speedway near New York is projected and in the Central West is a movement to build a circuit for track racing.

The Long-Stroke Motor for Cars

Part II

BY PROFESSOR W. D. ENNIS

The Engineering Problems of the Long-Stroke Motor Are Discussed in Both Theoretical and Applied Form—Tractive Force is the Real Criterion of a Motor's Value—The Longer the Motor Stroke the Slower the Crankshaft Speed and the More Durable the Engine—Motor Weight Per Horsepower Capacity Is Reduced—Greater Economy in Fuel Is Obtained—More Room for Accessories in the Long-Stroke Motor.

IN a previous installment of this paper, which appeared in THE AUTOMOBILE for November, the writer discussed some of the more evident and obvious factors which should be considered in fixing the ratio of stroke to bore in automobile motors. The present article deals specifically and quantitatively with these and some other more fundamental, if less apparent, factors. The tractive or pulling force exerted by a four-cycle gasoline motor cylinder is compiled from the established formula

$$F=\frac{pd^2sr}{2Nw}, \qquad \text{(I)}$$

in which

F = tractive force in pounds per cylinder, at the cylinder;
d = diameter of piston, in inches;
s = stroke of piston, in inches;
r = revolutions per minute of crankshaft;
N = revolutions per minute of road wheel;
w = diameter of road wheel in inches;
p = average pressure continuously maintained in the cylinder: say about 17 for an ordinary cylinder well operated, single-acting.

The tractive force actually available for propelling the machine will be reduced from this by from 15 to 25 per cent. at the motor shaft and by a further, probably approximately constant, amount at the rim of the wheel.

Since the quotient $\frac{r}{N}$ is what is commonly described as the *gear ratio,* the tractive force for a given car varies directly with the gear ratio. Now, the quantity d^2s may be written as $D \div 0.7854$, where D is the cubical displacement of the piston per stroke, for $0.7854\ d^2$ is the cross-sectional area of the piston and $0.7854\ d^2s = D$ is its displacement. Equation I then becomes

$$F=\frac{pDr}{0.7854 \times 2 \times N \times w},$$

and if we take $p = 17$, $\frac{r}{N} = g$, this gives

$$F=\frac{17\,Dg}{0.7854 \times 2 \times w}=\frac{10.82\,Dg}{w}. \qquad \text{(IIa)}$$

A 4 x 5-inch cylinder would have a displacement $D = 0.7854 \times 4 \times 4 \times 5$; its tractive force at a 10-to-1 gear would then be

$$\frac{10.82 \times 0.7854 \times 4 \times 4 \times 5 \times 10}{32} = 213 \text{ pounds},$$

if its wheels were 32-inch diameter.

Then the pulling forces, which can be theoretically exerted by *four-cylinder* motors under the assumed conditions, will be as shown in the chart, it being understood that the reductions previously referred to must be made if the results are to correspond with those of practice.

Terms for Tractive Force

Since s is the stroke in inches, $\frac{2s}{12}=\frac{s}{6}$ is the distance in feet traveled by the piston in one revolution, and $\frac{rs}{6}$, which we may call S, is the piston speed calculated in feet per minute. Then,

$$F=\frac{3\,pd^2S}{Nw}. \qquad \text{(II)}$$

Also, the circumference of the road wheel is equal, ignoring slipping of tires on road, to the distance traveled by the car in one revolution, and this is $\frac{\pi w}{12}$. In 1 minute the car will move $\frac{\pi wN}{12}$ feet, or in 1 hour it will travel

$$\frac{\pi wN \times 60}{12 \times 5280}=\frac{wN}{336} \text{ miles},$$

which speed we may call V_o.

Then
$$V_o=\frac{wN}{336}$$

and

$$F=\frac{pd^2S}{112\,V_o}=\frac{pd^2sr}{672\,V_o}. \qquad \text{(III)}$$

For $p = 17$, $F=\frac{d^2S}{6.6\,V_o}=\frac{d^2sr}{39.5\,V_o}$,

and if S be taken at 1,000,

$$F=\frac{151.5\,d^2}{V_o}. \qquad \text{(IV)}$$

This last expression is less general than any of the preceding, but is the simplest form possible, the ideal tractive force being a function of the cylinder diameter and car speed only.

TABLE OF THEORETICAL TRACTIVE FORCES.

Speed of Car, Miles per Hour.	Tractive Forces Per Cylinder, in Pounds, for Cylinder Diameters Stated.								
	4-in.	4¼-in.	4½-in.	4¾-in.	5-in.	5¼-in.	5½-in.	5¾-in.	6-in.
5	484	549	611	684	758	836	918	1000	1192
10	242	274	306	342	379	418	459	500	596
15	161	182	205	228	252	278	305	333	364
20	121	137	153	171	189	209	230	250	292
25	97	110	122	137	152	167	183	200	218
30	81	91	102	114	126	139	153	167	182
35	69	78	88	98	108	119	131	143	156
40	60	68	76	86	94	105	115	125	146
45	54	61	68	76	84	93	102	111	121
50	48	55	61	68	76	83	91	100	109
55	44	50	56	62	69	76	83	91	99
60	40	45	51	57	63	70	76	83	91

Equation IV holds only for a piston speed of 1,000 feet per minute, a figure roughly standardized as a basis for rating. The power of any engine may vary directly with its piston speed; the faster it runs, the more work it can do. The tractive *force* is, however, independent of the piston speed. This is true of both internal combustion and vapor engines. In the former, if the gear ratio be kept constant, a change in piston speed is absolutely without influence on the tractive force. See Equation I.

To show this most clearly, we write Equation I in the new form,

$$F = \frac{pd^2sg}{2w}, \qquad \text{(V)}$$

in which $G = \frac{r}{N} =$ the gear ratio as commonly defined.

Then an ordinary four-cycle motor at 3 to 1 rear axle gear, with 34-inch wheels on the car, should give for each 4½ by 4½-inch cylinder a pulling force of

$$\frac{17 \times 4\tfrac{1}{2} \times 4\tfrac{1}{2} \times 4\tfrac{1}{2} \times 3}{2 \times 34} = 68.3 \text{ pounds.}$$

Generally speaking, if we regard p as constant at 17 pounds, then for a given car at a given gear, g and w being fixed, the tractive force varies with d^2s; for the car considered, it is

$$\frac{17\, d^2s \times 3}{2 \times 34} = \frac{51}{68} d^2s.$$

Without gears an internal combustion cylinder could exert only one constant tractive force—the steam engine may cotinuously adjust its tractive force to the load by changing the point of cut-off and thus varying p. No great variation in mean internal cylinder pressure is possible or desirable in the internal combustion engine. The gears must be depended upon to vary the tractive force when necessary.

Since F is proportional to d^2s, it might appear that there is no special reason for increasing s in order to attain high tractive forces. But we must go into the matter more searchingly.

Piston Speed and Rotative Speed

In comparatively recent steam engine practice, a piston speed of 600 feet per minute was considered normal, and anything above this excessive; yet to-day in both steam and stationary gas engine design speeds up to 1,000 and even 1,200 feet per minute are common, and no serious disadvantages have accompanied these increased speeds. They have been attained, at least in steam engine work, *by increasing strokes* while leaving rotative speeds, revolutions per minute, as they were formerly. When the stroke of a releasing gear engine was limited to 48 inches, a piston speed of 800 feet was about the limit, because the releasing type of valve gear does not work well at rotative speeds exceeding 100 revolutions per minute. With a 5-foot stroke, the same type of valve gear permits of a 1,000-foot piston speed; and this with only minor difficulties, if any, with rod packings and guide and cylinder lubrication. It is the *rotative speed* that limits the performance of any engine, the revolutions per minute.

This is for two reasons: First, because certain types of valve gear, particularly those involving automatic features, do not work satisfactorily above certain speeds. In the internal combustion engine the use of positively actuated valves of the lift type, with suitably stiff springs, has placed this limit at least as high as 1,500 revolutions per minute, a limit far above any ever regarded possible in power plant engines, and probably never to be desirable for such service. Second, because a reciprocating engine wears out by reason of the shocks to which it is subjected. Every revolution includes two serious shocks, each comprising a total reversal of the direction of piston movement. The life of the engine may be expressed, other things being equal, in the total number of reversals it can stand. The more frequently these reversals are made, the shorter the life. High rotative speeds, therefore, implies durability, increase repair expense and decrease the useful life of the machine. The piston speed is a relatively minor matter. If high piston speed can be attained without high rotative speed, only minor difficulties will be encountered.

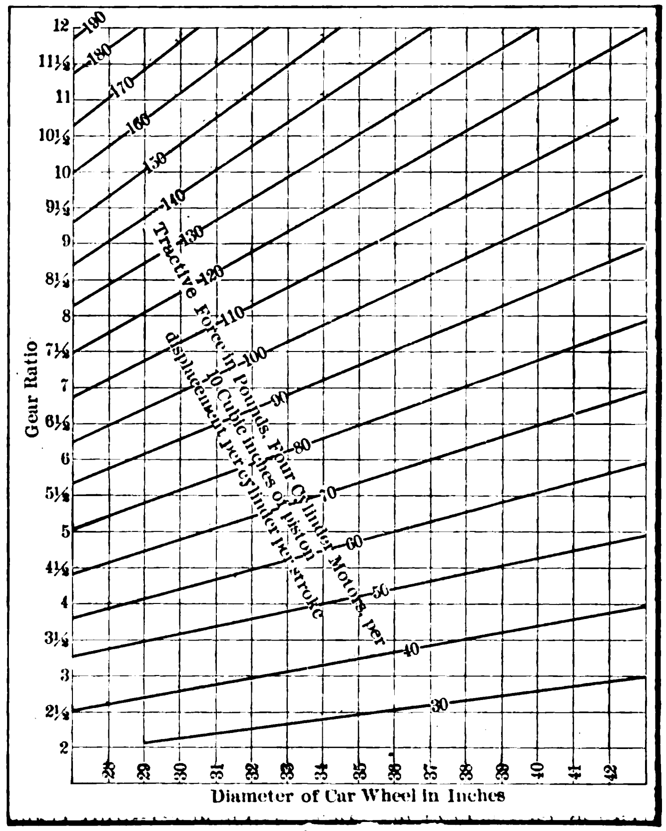

Fig. 1—Chart showing tractive force for various wheel diameters and gear ratios

The Long Stroke

To accomplish this end, the long stroke may be employed. For a given piston speed and horsepower the longer the stroke the lower will be the rotative speed and the more durable the engine. For a given number of revolutions per minute and gear, the longer the stroke the greater will be the piston speed, tractive force and horsepower. Design limits the revolutions per minute and running conditions determine the gear. The long stroke then gives maximum pulling force, power and speed. It may add slightly to the initial cost of the motor and may require special design in the arrangement of parts, but these disadvantages, if they are disadvantages, are trifling.

Efficiency of Long-Stroke Motors

The question is also worth considering from the standpoint of fuel economy. It is sometimes claimed, and the claim seems at first sight reasonable, that a long stroke gives opportunity for more complete expansion, and this improves the cycle of operations. The case is put as in Fig. 2. If 1234 represents the indicator diagram of the ordinary engine, increasing the stroke is thought to give the additional power 4561 at no increased expenditure for fuel. But it should be remembered that the pressure at the end of the suction stroke 71 is principally a matter of valve port friction, and is not much affected by the length of the stroke, so that compression in the long-stroke engine begins at 8 and its indicator diagram is 890*h*, as compared with 1234 for the ordinary motor. This diagram may still seem to give more work.

Let us carry the analysis a little further: Let the pressure at the beginning of compression be fixed. The law of the compression curve is probably not much influenced by the length of the stroke, so that to obtain the pressure and temperature prescribed by the nature of the fuel at the end of the compression stroke we must maintain a suitable volume ratio at the two ends of this stroke. In other words, the percentage of clearance should be the same no matter what the stroke of the engine. The compression pressure limits will then be the same for all strokes, but the volume limits will increase with the length of the stroke. The temperature and pressure after combustion will be unchanged, and consequently also the pressure at the end of expansion. Lengthening the stroke will thus be absolutely without influence on the pressure conditions of the cycle. The length of the indicator diagram will, however, be increased.

This true condition of things is suggested by Fig. 3. The indicator diagrams are 1234, 5678, the latter being for the long-stroke engine, and giving the greater amount of power. But this gain in power is not accomplished without cost. At the end of the suction stroke the cylinder is filled with combustible mixture at the pressure $P_1 = P_5$, at a definite temperature which is about the same for either type of engine, and a volume V_1 in the one case and V_6 in the other. The *weights* of mixture present in the two cases are directly proportional, therefore, to the volumes V_1 and V_5. At the end of the exhaust stroke there remains in the cylinder a volume V_9 or V_0 of mixture, the weight of which will be related similarly to its volume. The weights of mixture *drawn into the cylinders* will in the two cases then have the ratio

$$(V_1 - V_9) \div (V_5 - V_0),$$

or will be *proportional to the lengths of the indicator diagrams*, that is, to the displacements per stroke of the piston. And since pressure factors for the two diagrams are the same, the powers developed will be proportional to these diagram lengths, so that power ouput will be directly proportional to weight of fuel and air drawn in, and consequently *the ideal efficiency will be unaffected by the length of the stroke;* yet the longer-stroke engine may have certain practical advantages on the ground of reduced piston leakage.

Clearance in the Motor

In a steam engine clearance causes loss, and the effort is made to minimize it. In the internal combustion engine large clearance is necessary in order to obtain the pressure condition essential at the end of compression. While steam engine clearances vary from 3 to 8 per cent or more in small engines, and great refinement in valve design is practiced in order to reduce it, gasoline engine clearances may range from 20 to 40 per cent., and may as easily be too low as too high. In the steam engine the *amount* of clearance (linear) is practically fixed by the workmanship and the type of valve gear, and the *proportion* of clearance (in relation to piston displacement) is consequently reduced by using a long stroke, that is, a high piston displacement per stroke for a given cylinder area. No such argument holds in the automobile motor. It is true that short-stroke motors need less linear clearance than those of long stroke, but there are no designing difficulties in reducing linear clearance far below the permissible standard for internal combustion motors.

Some Practical Considerations

There are now to be considered some factors which, though permitting of less exact analysis, must be regarded in any final estimate. Among the incidental advantages claimed for the long stroke there are:

1. Reduced maximum pressures on parts.
2. Less motor weight per horsepower of capacity.
3. Longer life of motor.
4. Reduced wall area of compression space.
5. Greater economy in fuel.
6. More room for valves and better intake and sparking arrangements.

These we will now investigate.

1—Maximum Pressures

Assuming that the percentage of clearance is the same in both types of motor, then in Fig. 3.

$$P_2 = P_6.$$

If combustion is equally effective in both types,

$$P_3 = P_7 \text{ also.}$$

These latter pressures are the maximum *specific* pressures in pounds per square inch in the cylinder. The total pressure between piston and cylinder head at or near the end of the stroke is then

$$\frac{\pi}{4} d^2 P,$$

d being the diameter of the cylinder in inches and

$$P = P_3 = P_7.$$

At fixed piston speed and a given gear the horsepower of a motor is proportional to the square of the cylinder diameter. At a fixed rotative speed (the true determining condition) horsepower is proportional to d^2s, the square of the diameter multiplied by the stroke. An engine must be designed for a required tractive force and horsepower, so that the value of d^2s may be said to be fixed by the conditions. Suppose this value to be 125: so that if $d = 5$, $s = 5$; if $d = 4$, $s = 7.8$; if $d = 3$, $s = 13.9$, etc. The motors, 5 x 5, 4 x 7.8 and 3 x 13.9 inches respectively, will at uniform revolutions per minute all give the same power, but the maximum pressures for uniform values of P will vary as the squares of the diameters, or will be in the ratios $5^2 = 25$, $4^2 = 16$, $3^2 = 9$, being about three times as much for the 5-inch cylinder as for the 3-inch.

This enormous difference in pressures is directly related to

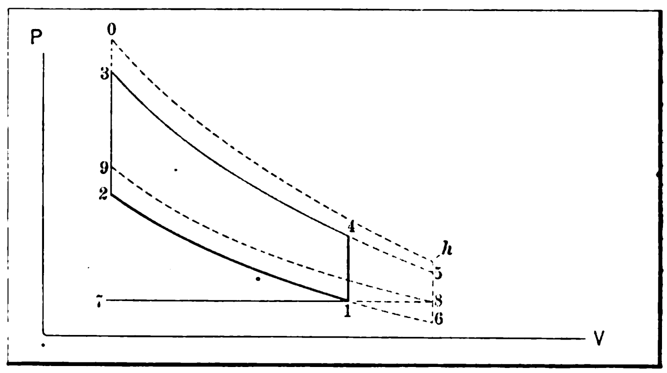

Fig. 2—Theoretical diagram showing the apparent increase in work by use of the long stroke

maximum stresses on cylinder head, piston pin, crank pin and shaft, and controls the design of those parts. Furthermore, the higher pressures cause more lost work in friction, and thus reduce the output of useful work from the engine.

2—Motor Weight

The wall area of the cylinder is made up of that of the head, $\frac{\pi}{4} d^2$, and that of the barrel, which we may call $\pi d s$. If differences in wall thickness be ignored the total wall area, volume of metal and weight of the cylinder will be proportional to $\frac{\pi}{4} d^2 + \pi d s$. This quantity increases less rapidly than the horsepower (a function of d^2s at constant revolutions per minute) as the diameter is increased, so that at first sight it would seem as if large diameters and short strokes were favorable to light weight per horsepower.

But the stress on the metal in the barrel of the cylinder is proportional to its diameter, and the wall thickness must be increased in the same ratio as the diameter, even though the specific pressure inside remains constant. We may, therefore, regard this part of the wall as varying in weight directly as $\pi d s \times d = \pi d^2 s$. The cylinder head may be regarded as a sort of compound beam supported at its rim and uniformly loaded. The breaking stress varies as the length of the beam, that is, as the diameter of the head, so that the weight of metal in the head is proportional to

$$\frac{\pi}{4} d^2 \times d = \frac{\pi}{4} d^3,$$

and the whole weight of metal in barrel and head varies as

$$\frac{\pi}{4} d^3 + \pi s d^2,$$

a quantity which for usual values increases more rapidly with d than does the horsepower. The long stroke may, therefore, reduce weight of motor per horsepower of capacity.

For example, compare a 4 by 4 motor with one 4 by 6. The horsepower capacities bear the ratio

$$\frac{4 \times 4 \times 4}{4 \times 4 \times 6} = 2/3 = 0.667.$$

The head areas are each $0.7854 \times 4 \times 4 = 12.6$ square inches. The wall areas are, short stroke, $3.1416 \times 4 \times 4 = 50.4$ square inches; long stroke, $3.1416 \times 4 \times 6 = 75.53$ square inches. The total areas are $50.6 + 12.6 = 63.2$ and $75.53 + 12.6 = 88.13$ square inches, respectively. The ratio of these figures is

$$\frac{63.2}{88.13} = 0.716.$$

Suppose the first motor to weigh 200 pounds and its output to

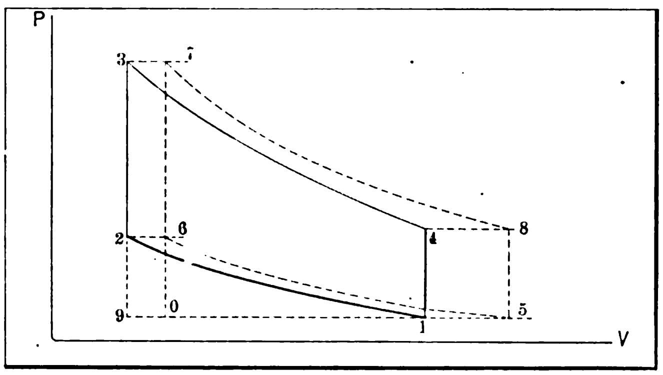

Fig. 3—The true gain in work is not so great as the apparent gain, as here shown

be 35 horsepower; then the second will weigh $0.716 \times 200 = 143.2$ pounds, and its horsepower will be $35 \times 2/3 = 23.3$. Its weight per horsepower is $143.2 \div 23.3 = 6.11$ pounds, while that of the long-stroke motor is $200 \div 35 = 5.71$ pounds. If the 35 horsepower had been obtained by increasing the number of cylinders of the short-stroke motor the required weight would have been $35 \times 6.11 = 214$ pounds, or 14 pounds greater than that of the long-stroke motor.

3, 5—Longer Life and Greater Economy

The former of these factors has been discussed under ***piston speed and rotative speed***, the latter under ***stroke and ideal diagram*** and ***clearance***. Some additional considerations as to the latter may be suggested by the paragraphs on ***maximum pressures***. A considerably longer life may be expected from the long-stroke motor; any direct increase in thermal efficiency due to its use seems likely to be small.

4—Reduced Wall Area of Compression Space

If a be the proportion of clearance, the length of the clearance or compression space is $a s$ and its side wall surface is $\pi d a s$. Adding the head surface, $\frac{\pi}{4} d^2$, we have $\pi d a s + \frac{\pi}{4} d^2$ as the total surface exposed to radiation at the end of the stroke. This varies more rapidly than the horsepower, as the diameter is increased, so that long-stroke motors have proportionately less wall area in the compression space than those of short stroke.

Consider a 4 by 4-inch and a 3¼ by 6-inch motor, both giving the same horsepower. If 30 per cent. of clearance is needed the linear clearance of the first motor may be taken as 1.2 inch, and its clearance wall surface is $(3.1416 \times 1.2 \times 4) + (0.7854 \times 4 \times 4) = 15 + 12.6 = 27.6$ square inches. That of the 6-inch-stroke motor (with 1.8 inch of linear clearance) is $(3.1416 \times 3\frac{1}{4} \times 1.8) + (0.7854 \times 3\frac{1}{4} \times 3\frac{1}{4}) = 18.3 + 8.3 = 26.6$ square inches, the slight advantage being in favor of the second motor.

It is difficult to see any vital importance in this peculiarity (at least in connection with automobile motors). Possibly the maximum pressure, $P_3 = P_7$, Fig. 2, might be increased slightly by a reduction of wall area, with consequent good results as to thermal efficiency, and, of course, some loss of any proposed advantages in respect to maximum pressures and motor weights; but the cylinder walls must be cooled anyway, and at high piston speeds with comparatively small cylinders it is doubtful whether any difference in maximum pressures or shape of expansion curves could be traced to a difference in wall area of compression space.

6—Room for Accessories

The necessarily longer clearance space does, nevertheless, affect in an important way the arrangements for admitting, igniting and exhausting the combustible mixture. The area of the head being $\frac{\pi}{4} d^2$ and that of the side walls of the compression space $\pi d a s$, while the prescribed volume of clearance space is $\frac{\pi}{4} d^2 a s$, we find that the space on the head varies as the clearance volume (and consequently at fixed revolutions per minute and clearance ratio, as the horsepower), while the available space on the side walls varies less rapidly. With long strokes and small diameters side wall space is more available for accessory attachments.

Summary of Facts

The long-stroke motor seems to have fully justified its existence. Some of the arguments advanced in its favor may fall to the ground under close examination; it is a mechanical rather than a thermal device, and its advantages are mechanical rather than those related to thermal efficiency. In steam-engine practice equality of bore and stroke is a feature only of high (rotative) speed engines. With piston speeds pretty well standardized, the higher the rotative speed the shorter the stroke, and the lower piston speeds, shorter strokes and higher rotative speeds have all been necessarily associated with the smaller engines. This condition of things probably influenced early standards in the design of internal combustion motors There is no sufficient reason why it should continue to do so. It was a wrong condition, and steam-engine builders are now resorting to higher piston speeds, particularly in large units. Large gas engines have led the way by demonstrating the feasibility of piston speeds exceeding 1000 feet per minute. With the high-duty requirements of the automobile motor it is reasonable to go still further, and if 1000 revolutions per minute has been found satisfactory for a 4-inch stroke, giving 1000 feet piston speed, the same rotative speed with a 6 or 7-inch stroke, giving 1500 to 1750 feet piston speed and an increase of 50 to 75 per cent. in power with the same diameter of cylinder, is justifiable.

Cleaning Rusty Parts—It has been discovered by accident that a rusty part which could not easily be cleaned by pickling in an acid bath can be disposed of quickly by first immersing it in a strong alkaline bath, which also serves to remove whatever grease may adhere to it. A strong solution of soda or caustic potash is heated and the part is left one-half hour therein. Then a solution of one part of hydrochloric (muriatic) acid to four parts of water will remove the rust. Thereafter the part is rinsed in a weak solution of carbonate of soda and brushed with water and pumice. The rinsing is necessary only if the part must be used at once. Otherwise it is simply wiped dry.—From *Cycle et Automobile Industriels*.

Digest of the Leading Foreign Papers

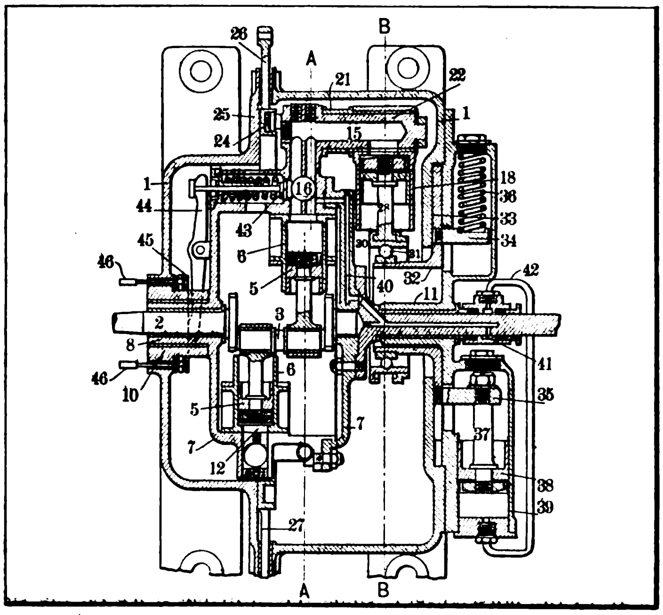

Fig. 1.—The Louis Renault hydraulic transmission

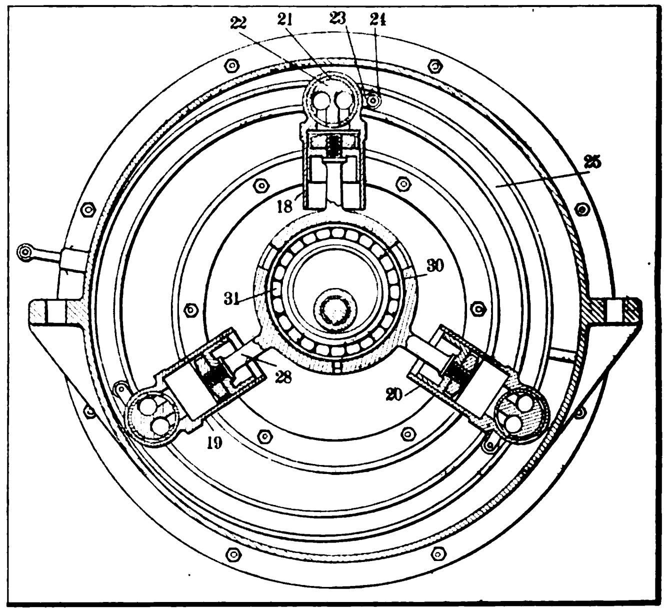

Fig. 2—Mounting of driven pumps—Section B B in Fig. 1

Hydraulic Transmissions—II
Renault and Hele-Shaw Types

THE author describes and illustrates a series of mechanisms in which the functions of an infinitely graduated clutch, permitting the starting of a vehicle—a heavily loaded truck for example—at a highly reduced speed, are supposed to be combined with those of a change-gear mechanism, by which the power applied to the driving wheels is increased in proportion as their speed is reduced. In a preliminary discussion of the subject it was argued that in most hydraulic transmissions the designers are deluding themselves with regard to the power obtained at low vehicle speed. The reduced speed of the drivenshaft is generally obtained by a graduated slip in the action of the oil against the driven parts, which slip, however valuable for clutch and starting action, creates friction in the oil conduits and is consequently transformed into heat, but is not delivered to the drivenshaft in the form of power. In one part of the series, the Williams-Janney hydraulic transmission, in which this defect is to a great extent avoided, was described in THE AUTOMOBILE of November 2, and this construction, which has been adopted by the Delaunay-Belleville company of France, is a modern adaptation from the American Cooper-Hampton patent of 1894. Among other constructions described those designed by Louis Renault of France and Professor Hele-Shaw of England, are notable by reason of the prominence of the designers and the fact that in both a direct drive at the adjustment corresponding to high gear in a mechanical transmission is obtained by locking the driving and the driven parts together by immobilizing the oil between them. In neither case, however, does the author seem to consider that the power efficiency at low vehicle speed has been established.

By carefully following the reference numerals on Fig. 1, while realizing that each of the three driving pumps in this relatively complicated mechanism has a corresponding driven pump and that the oil piping connecting them is partly transverse of the mechanism and partly circumferential, the reader may arrive at an understanding of the Renault hydraulic change-gear and transmission, the patent for which dates back to 1906.

In a general way the mode of operation is as follows: When the pistons 5 of the three driving pumps are prevented from moving because the passages are closed which connect the oil in them with the circulation, the rotation of the motor shaft 2 effects, instead, the rotation of the inner casing 7, to which the driven shaft 9 is secured, and the latter is therefore rotated as in direct drive. If the passages are open which permit oil discharged from the driving pumps to go freely into the circulation without passing through the driven pumps, the transmission is in neutral. If these passages, valves 43 in the drawing, to the circulation (the mass of enclosed oil) are closed, the driven oil exerts a pressure upon the pistons of the driven pumps, but these are mounted upon a ball-bearing which is normally concentric with the axis of rotation of the mechanism and cannot reciprocate; in other words, the driven pumps cannot discharge oil and the drive is therefore still direct. It is, however, only a strong spring, 36, which holds the inner ends of the driven pistons in their inoperative position of concentricity. Suppose the throttle of the motor is opened wide while the load is much increased, the pressure on the driven pistons is then much increased and may be sufficient to overcome the spring resistance referred to. To this end passages communicate the pressure to a separate adjustment piston, 37, working in a separate cylinder, by the movement of which against the spring's resistance the sleeve is displaced more or less from the concentric position. The greater the surplus pressure over and above that of the spring, the greater the displacement and the resulting eccentricity. Now, the driven pistons are enabled to reciprocate, the valve mechanism being of course such as to coordinate their movements with those of the driving pistons and with reference to the masses of oil displaced in each system of pumps, the driving and the driven. If the driven pistons are adjusted so as to discharge only a small portion of the oil which the driving pumps could deliver if they were free to move, the action of the driving pumps will be correspondingly reduced (as on direct drive it is reduced to nothing) and the balance of the available energy in the motorshaft will be expended in turning the inner casing 7, and the drivenshaft secured thereto; the speed of the drivenshaft being reduced as compared with that of the motorshaft in proportion as more or less oil is permitted to escape through the driven pumps.

When high pressure in the whole system of passages causes the ball-bearing sleeve which determines the possible movements of the driven pistons to take a strongly eccentric position, the rotation of the casing 7 and of the drivenshaft is of course reduced to a minimum, and it seems to be the designer's idea that for this reason the mechanism accomplishes the same that is accomplished on the low gear of a mechanical transmission. The author, on the other hand, considers that the designer has produced only a clutch, with graduated slippage.

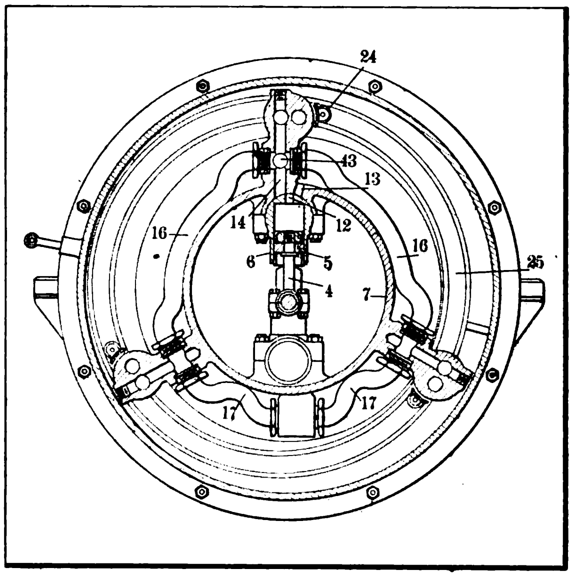

Fig. 3.—Transverse section of Louis Renault hydraulic transmission, on line AA in Fig. 1

The detail of operation of this hydraulic set follows: The motor shaft 2 controls the three pistons 5 which move in pump cylinders 6 pivotally secured to a drum 7, to which is secured in turn the driven shaft 9. The pumps communicate with the fluid in the drum and casing through the passages 12, which alternately register with the admission channel 13 and the discharge pipes 14, and they communicate mutually as well as with three largerdriven pumps 18, 19 and 20, Fig. 2, by the passages 15 shown in Fig. 1 and 16 and 17, shown in Fig. 3. The fluid feed of the driven pumps is regulated through the cylindrical distributers 21 around which the pumps oscillate and which themselves oscillate on the shafts 22 with a movement controlled from the crankarms 23, which moves on rollers 24 in the circular path 25, and whose eccentricity with relation to shafts 2 and 9 is regulated by the rods 26 and 27.

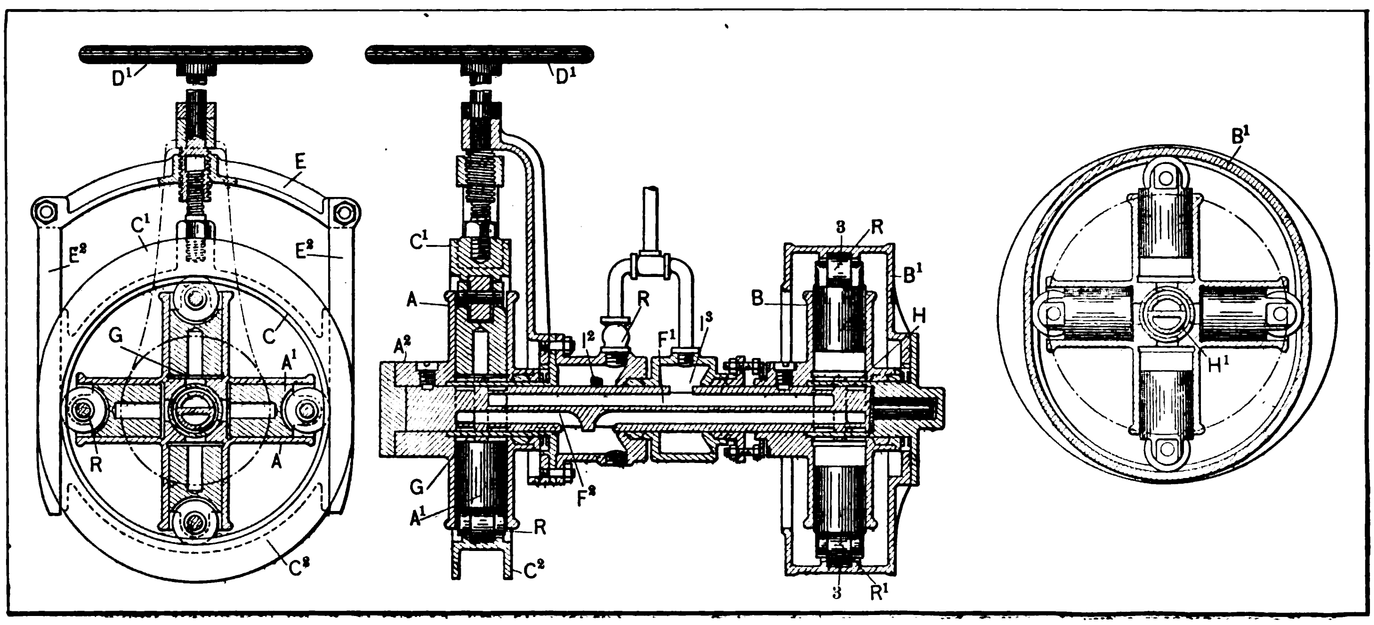
The piston rods 28 of the driven pumps are fixed upon the outer race 30, of ball bearing 31, mounted upon the sleeve 32, which forms the integral cylindrical hub flange of plate 33, which may be placed in a more or less eccentric relation to the axis of the mechanism, being controlled in this respect at 34 and 35 through the spring 36 and the piston 38, the latter moving in a cylinder 39, which communicates with the two systems of pumps by channels 42, 41, 40 and 16.

Normally spring 36 maintains 32 concentric with driven shaft 9 and, in this adjustment, if the valve 43 is opened by means of the control device 46, 45 and 44, so as to place the pipes 16 in direct connection with casing 1—full of oil—and with drum 7, the three pumps 6, turned by shaft 2, will draw oil therefrom and will discharge it into 15, 16 and 17 without the fluid exerting any notable pressure on the pistons of the driven pumps. If 43 is closed, this pressure is increased but without displacing the pistons of these pumps, because the cylindrical flange 32 is concentric with shafts 2-9; and the drum 7 and shaft 9 are drawn along together at the speed of the motor shaft 2.

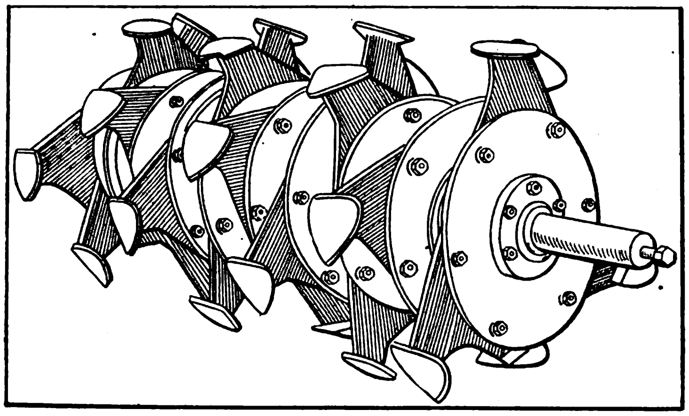
If the pressure in the oil circulation is increased beyond the limit determined by spring 36, piston 38 is moved and displaces plate 33, with its flanged hub 32, eccentrically, so that the pumps 18, 19 and 20 begin to discharge oil proportionately to the eccentricity. The speed of shaft 9 is hereby automatically reduced in proportion to any increase in the resistance against its rotation.

To reverse the vehicle movement, it is sufficient to apply the control levers 36 and 37, which act on the locking device 25 by which the eccentric adjustment of the driving pumps may be changed about, causing the periods of oil intake and oil discharge in the driven pumps to be reversed with relation to those of the driving pumps 6. Shaft 9 will then turn in the opposite direction to that of the motorshaft and with less speed.

In the Hele-Shaw hydraulic transmission, Fig. 4, the system of driving cylinders A and the system of driven cylinders B are both secured upon the shaft F. The pistons of cylinders A impinge by rollers upon a circular track in two parts, C_1 and C_2, the latter integral with or secured to the control system E and E_2, which may be operated by means of the handwheel D_1 so as to separate the two parts of the track, thereby varying its shape from circular to oval. The rollers R_1 of the driven cylinders B travel on an elliptic path B_1, Fig. 5, which is not subject to variation. The intake and discharge of oil from cylin-



Figs. 4 and 5—Cross and transverse section of the Hele-Shaw hydraulic transmission



Combined rotary plough and harrow tool, made in Germany

ders A and B are regulated by the circular valve disks G, Fig. 4, and H1, Fig. 5, which are secured respectively to shaft F and to B1. If the track C1-C2 is maintained strictly circular, the motor shaft A2 rotates the whole system, A, F. B, and B1, as a unit, the immobility of the pistons A1 in their cylinders preventing the pistons of the B system from budging in theirs, and causing the B system to take along the oval track B1 and the driven shaft which is secured to it, as if these parts were integral with the motor shaft and the system of driving cylinders. The pistons of the B cylinders will, on the other hand, be free to move in proportion as the parts C1 and C2 are separated (ovalizing the track for the rollers of A), and if their movement is sufficient to cause the cylinders B to accommodate their positions to the ellipticity of the track B1, at the speed of the motor shaft's rotation, B1 will remain stationary. This is the result when the C track is adjusted to be as oblong as the B1 track always is. At a further lengthening of the C oval, the reverse should be effected. On the other hand, the nearer the C track remains to the circular shape, the smaller is the angular velocity of B1, but it seems questionable if the force which compels B1 to rotate under these circumstances is efficiently applied or is mainly to be looked upon as wasted in slip between the rollers of cylinders B and the track B1.

The return channel for the fluid, through the interior of shaft F, is in communication, at I3, with an oil reservoir from whose oil reserve losses from leakage are made good; and the pressure-channel F2 communicates, at I2, with a valve R which limits the pressure in the mechanism.—From serial article by Ch. Faroux, in *La Vie Automobile.*

Motor Power Creates New Farm Implements—In the manufacture of agricultural motor implements the thought is coming to the surface that it should be possible to do with a single tool the work which is now either done imperfectly with the plough alone or with considerable waste of labor succesively with a plough and a harrow or with spade and hoe. The perfect condition in which, for example, the mole leaves the ground which it throws behind it, suggests a tool somewhat of the shape of its obliquely working shovel-like forefeet provided with pointed claws on the cutting edge. An innovation in this direction is the Linard-Hubert motor plough with "striking shares" which took part in recent agricultural contests in France. Another is shown in the accompanying illustration of the tool used with the farm-work tractor made by Heinrich Lanz of Mannheim, Germany, under patents to Koeszegi. This tool is a rotary hoe. The triangular hoe blades are not tangential to the circle in which they rotate but at a sharp angle with a tangent and have been found efficient in various trials by agricultural societies in Germany for producing the desired loosening of the deeper portions of the soil as well as the proper mixing of manure with the top soil, while the edges of the discs of which they form a part take care of the first breaking of the surface.—*Deutsche Technik,* November 1.

Harking Back a Decade

FROM *The Motor Review,* December 5, 1901:

Banker Brothers have incorporated under Pennsylvania laws under the title Banker Brothers Company, capital $50,000. The company is considered the largest dealing in motor vehicles at retail in the United States. It has taken on the Peerless line in addition to its other stock.

The horse-drawn stages on Fifth avenue, New York, are all destined for the discard. The new electric stages with red wheels and yellow bodies make a fine show.

With the first of the year the Winton Motor Carriage Company announces that its capacity will be between twenty and twenty-five complete automobiles a week. J. Bechtel, formerly superintendent of the Black Manufacturing Company, at Erie, making bicycles, has been added to the Winton staff as a mechanical expert.

William E. Metzger has been appointed Detroit agent for the Winton. Carl G. Fisher, of Indianapolis, will distribute the Winton line in that territory. Harry Fosdick, of the Locomobile Company, has resigned to accept the Winton agency in Boston.

The Stearns Steam Carriage Company announces that in future when it sells a car, it will send an expert instructor with the car to its purchaser to teach the buyer how to run it. The buyer is expected to pay the expert's expenses, but the company will pay his salary.

The first motor delivery wagon to make its appearance in Lawrence, Mass., is a steam car made by the Mobile Company of America. It has a covered body, capacity of 1,600 pounds and a speed of 20 miles an hour.

The Knox company secured enough business from the recent show to keep its factory busy on three and four-wheelers for a period of three months. The four-wheel model for 1902 is an attractive car and proved itself a hill-climber recently by going up the Cross street hill at Springfield, Mass., making the ascent half way on high gear. The car performed well despite the fact that it was a crisp morning.

The E. R. Thomas Motor Company explains the fact that its new cars were not exhibited at the recent show on the ground that it does not believe in fall shows. The chief objection raised was that other manufacturers attend fall shows simply to get ideas for their own product. Hence it reserved its exhibit until a time when it will be too late for competitors to copy.

The first race meeting ever held in Washington took place Thanksgiving Day. Three events were run, one of which was for gasoline cars. This was captured by Lewis Hill, name of car not given.

The National Capital Automobile Club and the Washington Touring Club have decided to amalgamate. The new clubrooms will be in the Pope building.

Ten members of the Rhode Island Automobile Club have contracted to buy 20-horsepower Winton cars especially adapted to racing. Plans are on foot to build or secure a race track near Newport.

Exports of automobiles and parts from New York for last week were just under $7,000 in value.

The Krastin Automobile Manufacturing Company, recently incorporated at Cleveland, expects to employ 200 men in its new plant. The company has experimented with a new type of gasoline automobile and expects to begin operations immediately.

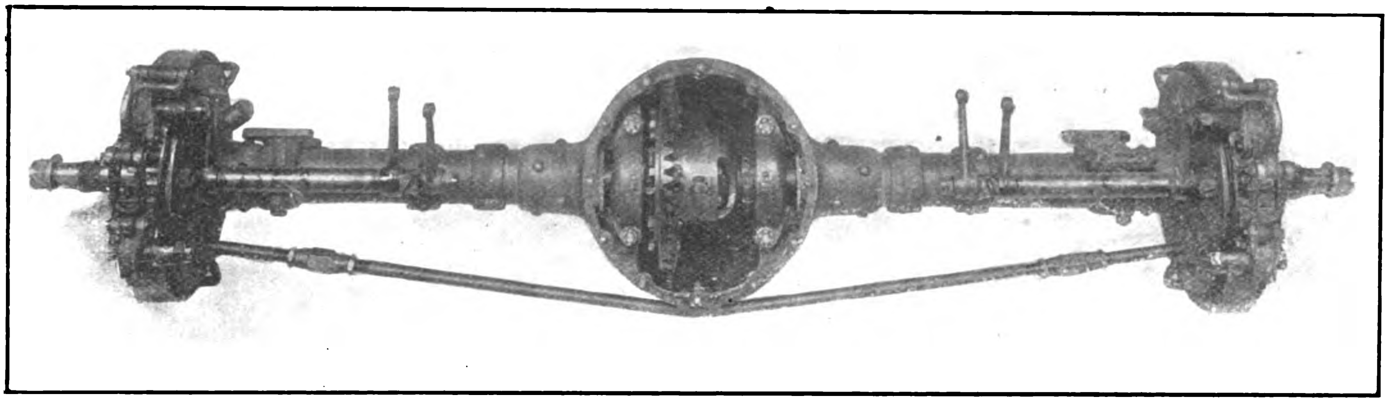


Fig. 1—View of the G. J. G. rear axle, showing rigid construction

Unit Power Plant Features the G. J. G.

FOR the season of 1912 the G. J. G. Motor Car Company, of White Plains, N. Y., has brought out a chassis, equipped with a unit power plant. The motor has four cylinders cast in pairs, with a bore of 3 3-4 inches and stroke of 4 1-2 inches. The horsepower of the motor is rated by the makers at 26. The valves are all on the same side of the cylinder. Water jackets are cast integrally and are made so as to provide easy water circulation. The material from which the cylinders are made is reverberatory air-furnace iron. To provide an easy turning moment for any position of the piston the cylinders are offset a distance of 3/8 inch.

The pistons are made of extra length so as to provide a good bearing surface, and eliminate chances of compression leaks. They are provided with three eccentric rings fitted with lap joints. The material in the pistons is also of reverberatory air-furnace iron, and in order to provide for a good fit, both the pistons and rings are ground to size. The wristpin is fitted into a bushing of good size and so arranged as to give a small amount of clearance for the upper connecting-rod bearing. The wristpin bushing is open at either end so that oil may pass into it, and through an opening into the bearing. There is a slight counterbore in the cylinder just above the top of the stroke.

The connecting rods are fitted to the wristpin by a clamp joint through which a bolt passes by means of which the tightness of the wristpin bearing may be regulated. At the lower end of the connecting rod the bearing is of good width. The material in the connecting rods is open-hearth steel, and they are drop forged and hardened. At the lower end they are fitted with bushings of die-cast cadmium nickel bronze. The connecting rods are of I-beam section, according to the usual practice.

The crankshaft is made from a drop forging of carbon steel which is heat-treated and ground. It runs upon three main bearings and is flanged at the rear end in order to provide a fastening for the flywheel, which is bolted thereto. The three bearings are located as follows: two at the ends of the crankcase and supported by webs in this casting, while the third rests upon a bridge formed by a vertical partition which extends across the crankcase.

The camshaft is a one-piece forging hardened and ground to size, and having large diameter. The cams, which are integral parts of the camshaft, are provided with a wide face to eliminate rapid wear. The camshaft is driven by means of three spur gears located in a casing at the forward end of the motor. This casing is shown at G, Fig. 3. These three gear wheels constitute the entire driving mechanism for the camshaft, water pump, magneto, etc., and hence noise due to clashing gears is eliminated as far as possible. The valves are made with nickel steel heads and carbon steel stems, and are set side by side on the left side of the motor. The lifter rods are actuated directly by the cams, and the mechanism is made certain by the employment of large springs which are fitted on seats just above the adjusting screws. The springs and adjusting nuts are readily ac-

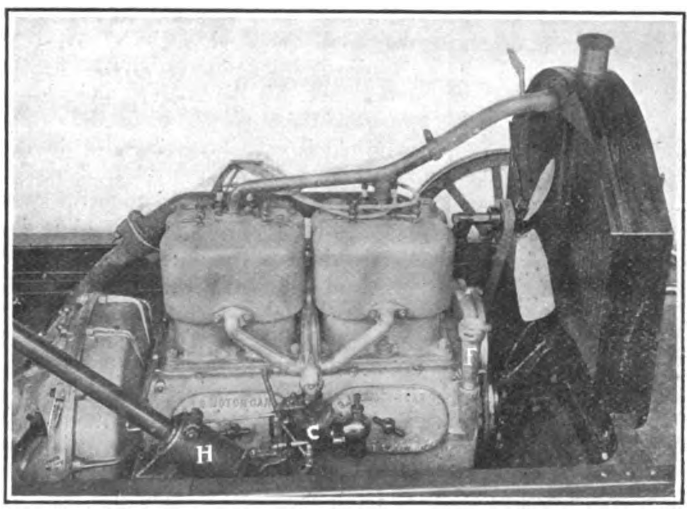

Fig. 2—Water and gas manifolds are cast integrally

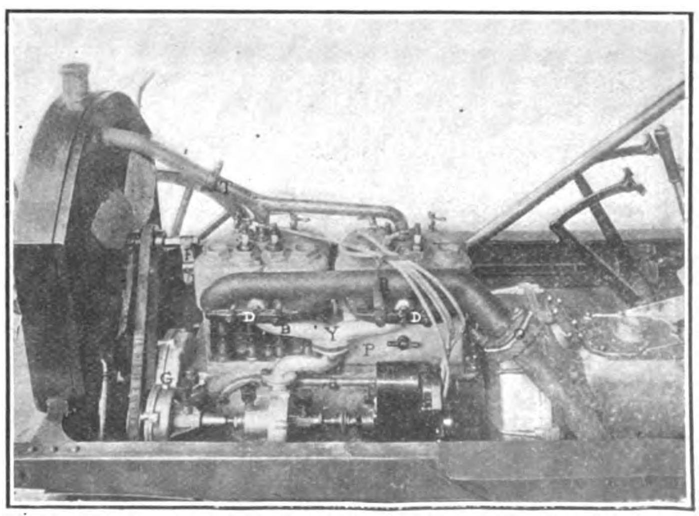

Fig. 3—The compact valve side of the G. J. G. motor

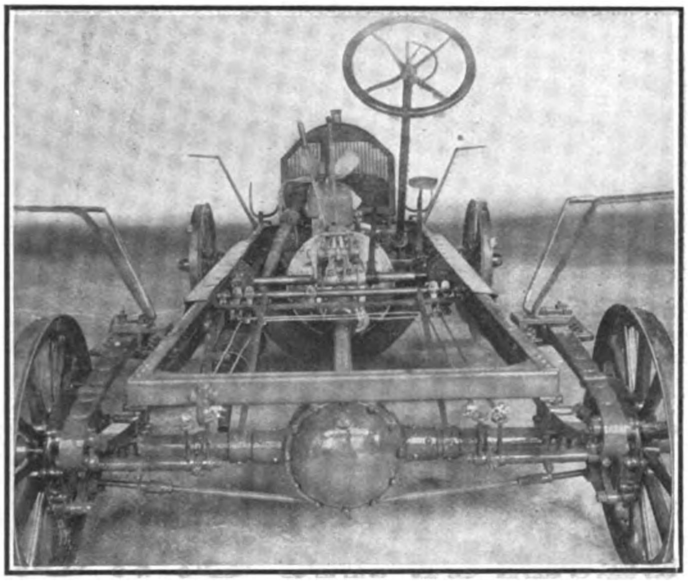

Fig. 4—End view of chassis, showing rear axle suspension

cessible by the removal of the side cover-plate P. This cover plate is held by a bolt which can be turned by hand as may be seen from the illustration. The adjustment nuts are for the purpose of regulating the valve action when it becomes necessary after having ground the valves to a considerable extent. These adjustment nuts will also compensate for wear in other parts of the valve mechanism.

The water by means of which the motor is cooled is circulated by a centrifugal pump which is driven by a gear through a transverse shaft. The water intake manifold surrounds the gas intake manifold and passes from the left side of the motor between the two central cylinders transversely across the crankcase to the right side of the motor. After having passed clear of the cylinder castings the water intake pipes are led to the lower part of the jackets on the right side of the motor, and are fastened there by elliptical flanges through which pass two bolts. After having circulated through the jackets, which are so shaped as to be wider near the top, or more heated part of the combustion chamber, the water is led back to the upper part of the radiator. The connection between the water outlet manifold and the radiator intake is of rubber hose 1 1-4 inches in diameter. It is fastened to the manifold by means of a clip T. A similar clip secures it to the intake pipe of the radiator. The radiator is of the Mercedes type and is cooled by means of a four-bladed aluminum fan, driven by an adjustable belt from the forward end of the magneto shaft. The fan bracket is supported by a small flange on the forward end of the first cylinder at F.

The lubricating system is a combination of the force-feed and gravity methods. The oil is contained in a reservoir which is formed by the lower part of the crankcase casting. A gear pump at the forward end of the casting lifts the oil from the reservoir and transmits it to a lead above the crankshaft. This oil flows into pockets along the walls of the base chamber so arranged as to lead directly through ducts to the main bearings. The oil flows through these ducts by gravity and amply lubricates the bearings, which are lined with die-cast cadmium nickel bronze scraped to fit.

Other leads are fitted over the crank bearings and so arranged that the oil will also flow into them by gravity, thus giving them an ample supply. Besides lubricating the crank bearings the oil will be thrown by centrifugal force, due to the rapidly revolving crankshaft, up into the cylinders, the walls of which will be covered by a supply of oil after the engine has been running for a short time. The piston on its downward stroke becomes covered with the oil, then on the next succeeding upward stroke carries it to the upper part of the cylinder, thus lubricating this important member. Besides lubricating the cylinder the oil thrown off the revolving crank also lubricates the camshaft and all other revolving parts of the motor.

Details of the Lubrication Scheme

After having lubricated the motor the oil will drip back to the lower part of the casing and eventually drain to the bottom of the crankcase. A screen is inserted through which all the oil must pass before it can again enter the oil pump. At the suction opening of the oil pump there is a slight depression in the bottom of the crankcase reservoir which forms a sort of oil-well. This depression will insure a quantity of oil for the pump in case the engine should be going up a hill without having an ample supply of oil in the base. The pump is on the same shaft as the timer and is so arranged that no stuffing gland is used; therefore, there will not be any chance of leakage at that point. On the right side of the crankcase at the forward end there is a projection into which the oil filler pipe F, Fig. 2, is inserted. It is provided with a screen of wire gauze through which the oil which is put into the crankcase must pass. This precaution obviates the chances of waste or other foreign material entering the crankcase while the oil supply is being replenished. The crankcase which contains the oil system is of aluminum alloy of barrel design. This construction gives great rigidity and durability.

Ignition is effected by means of the Bosch dual system, consisting of Bosch high-tension magneto, which delivers current to one set of spark plugs while an independent set of spark plugs may be used in combination with a battery and coil set for starting purposes.

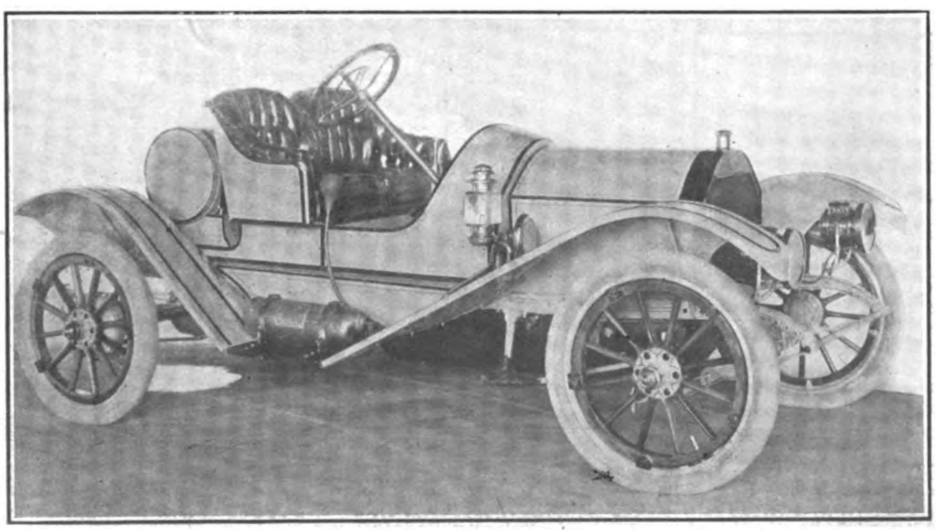

Fig. 5—Runabout body which is fitted to the G. J. G. chassis

The carbureter C is located on the right side of the motor supported by the intake manifold, which passes as described from the carbureter to the other side of the motor, and thence to the intake port. Since the water manifold is cast integrally with the gas manifold a uniform quality of gas is assured at all times on account of complete gasification of all the gasoline due to the heat. The intake manifold is provided with a flange to which the Y-shaped piping is fitted as shown at Y, Fig. 3. From this point the gas passes directly to the intake ports.

The exhaust manifold is provided with an outlet of 2-inch steel tubing. It is held in position by means of broad flanges and stud bolts B which pass through the dogs D. On the rear dog a clip is fastened as shown at R which holds the wires from the magneto and secures them against the vibration of the car. The exhaust manifold is led back to a position parallel to the rear end of the rear cylinders. It then dips down and ends in a flange at Q where the exhaust pipe which leads to the muffler is joined to it and held tight against leakage by means of a gasket fitted between the flanges.

The clutch is of the multiple-disc type and is contained in the flywheel. A view of the clutch housing may be had in Fig. 7 at C. This housing, which is continued back from the crankcase, is of aluminum alloy and ribbed so as to give strength and rigidity. A vertical flange passes around the circumference of the housing and forms the means of connection between it and the gearset housing. A hand-hole is fitted at H so that inspection is easily possible. The clutch is so designed that a constant stream of oil is poured upon it while the engine is in motion. The discs of which the clutch is composed are of saw steel tempered and ground. The clutch is operated by means of a pedal shown at P, so constructed that a very light pressure upon it will release the clutch.

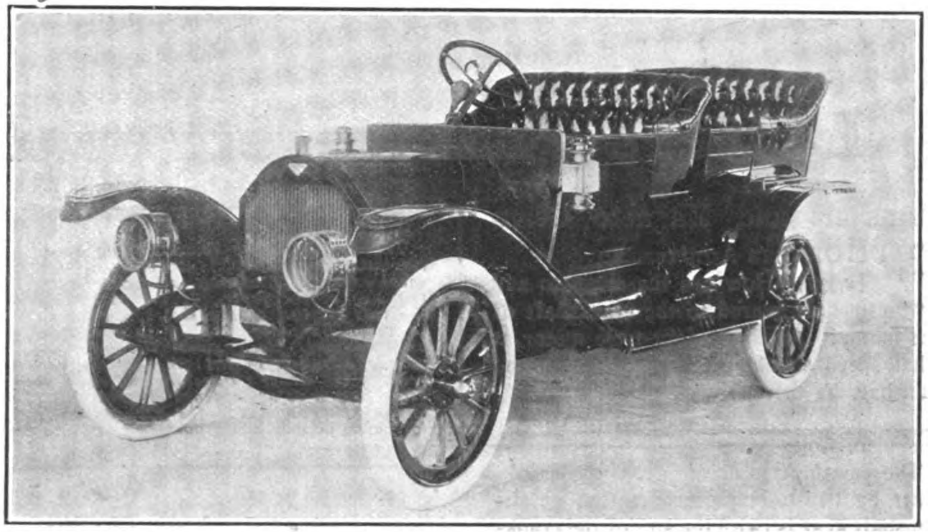

Fig. 6—The G. J. G. fore-door touring car for 1912

Power is transmitted through a short shaft to the gearset. This is of the three-speed selective type, having 2¾-inch shifter rods extending from the rear of the case. Each of these shifter rods is 1⅜ inches from the center line of the motor and 4 14/32 inches above the shaft. The change speed lever is shown at L and works in the H-quadrant Q. The gearset shafts are carried on imported ball bearings, while the gears are all designed so as to have a large diameter and a wide face. The material of the gears is high carbon steel, heat-treated and hardened. The gear-shifting shafts are equipped with a positive interlocking system so arranged as to positively eliminate the possibility of two pairs of gears being in mesh at the same time. All studs, nuts and shafts are made from selected high-grade steel.

A universal joint fitted in the casing D takes up the transmission of power from the gearset and delivers it to the propeller-shaft. The propeller-shaft is surrounded by a torque-tube in order to eliminate strains due to irregularity of the road.

From the propeller shaft the drive is transmitted to the differential and semi-floating rear axle and thence to the rear wheels. The rear axle is encased in a pressed steel housing which is fitted at the differential with a circular inspection plate. In order to provide stiffness a tie rod is fitted which passes from the extremities of the axle beneath the differential casing and is joined by turnbuckles upon which adjustments may be made for tightness. The front axle is an I-beam drop forging having the spring seats forged integrally.

The Braking System Is Adequate

The brakes are on the rear wheels and work through equalizers on 10 3-4-inch brake drums. The service brakes are operated by means of a pedal, while the emergency brakes are controlled by the lever B, Fig. 7, on the left side of the driver's seat. The wheels are of the wood artillery type, having twelve spokes both front and rear. They are adapted for 32 x 3 1-2 inch tires all around. The tread is 56 inches, and the wheelbase 104 inches.

The chassis frame is of channel construction without drop. It is supported in front by semi-elliptic springs, while in the rear the springs employed are elliptic with scroll ends.

The steering gear is of the irreversible worm-and-sector type. It is inclosed in a housing at the lower end which may be seen at H, Fig. 2. The hand wheel is of 18-inch diameter constructed on an aluminum spider which holds the spark and throttle levers and quadrants. There is an adjusting screw fitted so that all wear on the worm may be taken up, thus increasing the life of this part of the steering gear. The control of the car is by means of the spark and throttle levers on the steering wheel, the brake and clutch pedals, and the two levers which are located on the left side of the driver's seat. An accelerator is also included in the equipment of the car, as well as a muffler cutout.

Other equipment consists of a full set of Dorian quick detachable, demountable rims, with an extra rim, gas head lamps and Prest-O-Lite gas-tank, oil side and tail lamps, horn, tire repair kit, oil can, pump, jack and full roll of special tools. The color is coachbuilder's deep blue, with black stripe, gold hairlines, and black leather upholstery. The bodies furnished on this chassis are the runabout or touring type as desired.

Pistons of Aluminum Alloy—Several German, French and English houses now produce aluminum alloys whose strength and fusion point are sufficiently high to admit of the material being used for pistons and connecting rods. Such parts would have not only the advantage of lightness but, at equal strength with parts of steel, would be superior in rigidity and in ability to carry away heat from the combustion chamber. For this purpose the piston made of aluminum alloy might be provided with interior radiation fins, as has been done in a few instances before suitable alloys had been made commercially available.—From *La Vie Automobile*, Nov. 4.

Letters Answered and Discussed

Camshaft and Magneto Gears

EDITOR THE AUTOMOBILE:

[2,937]—How are the magneto and camshaft geared to the crankshaft of the motor? And in a four-cycle motor at what speed should the magneto-shaft and camshaft be driven?

C. B. AMES.

Pueblo, Col.

The camshaft is driven from the crankshaft by two-to-one gearing; that is, the camshaft gear is twice the size of the crankshaft gear, and hence the camshaft rotates at half the speed of the crankshaft. Usually the magneto is driven at the same speed as the latter. Fig. 1 shows the relative sizes of these gears and the way they are connected when a single camshaft is used; that is, when the valves are all on one side of the motor.

Nut-locking Device

Editor THE AUTOMOBILE:

[2,938]—Do you know of any way of preventing the jarring loose of small nuts (such as those on the magneto and carbureter), due to the vibrations of the motor

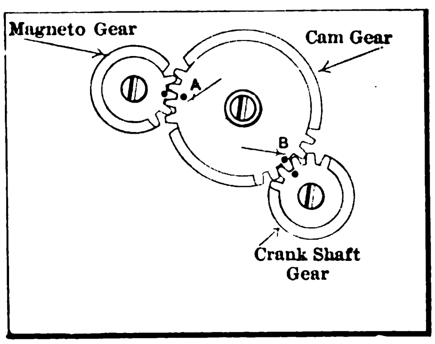

Fig. 1—Gearing for driving magneto and camshaft

and jar of the road? I have lost a number of them in this way and have wondered if there was not some means of holding them except by the use of an extra nut as a locknut.

C. N. TAYLOR.

Murfreesboro, Tenn.

Perhaps the form of locking device which you desire is shown by Fig. 2. This does not require the use of an extra nut, and is very simple. The spring piece is fastened with a pin at the smaller end and the other end is made so that it will just fit over the nut. When the nut is to be turned the piece is pressed down until the nut is clear. You should be able to purchase these holders where automobile supplies are kept, although it would not be a great deal of trouble to make them yourself.

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

More Acetylene Gas Trouble

Editor THE AUTOMOBILE:

[2,939]—I have had considerable trouble with the gas supply for my headlights. They frequently sputter and go out when I am on the road and I find it necessary to blow out the piping in order to rid the system of water before I can get them to burn again. Is there any way to prevent this water from getting into the piping? I use an acetylene generator.

M. E. LONG.

San Francisco, Cal.

The way to rid the system of this water is to slant the gas piping down to a condensation trap. This trap should be drained occasionally in order to remove the accumulated moisture. It is a good plan to blow out the piping with a pump from time to time also. In our issue of November 9, on page 817, will be found an illustration showing a trap of this kind in place.

Horses vs. Motor Trucks

Editor THE AUTOMOBILE:

[2,940]—As a subscriber to your valuable magazine, I wish to ask if you can furnish any data regarding the relative cost and saving between a motor truck and a horse-drawn vehicle. Any figures that you may be able to furnish will be greatly appreciated.

CHAS. F. MACKIN, JR.

Newark, N. J.

Any data that could be given in this connection would be of little or no value, as the conditions under which motor trucks are operated vary widely. The question of care in operation would also enter, thus involving the human element. When the speed and carrying capacity of the average large motor truck are compared with those features of the horse-drawn vehicle the former would seem to have sufficient advantage to counterbalance its increased first cost and expense of maintenance.

From figures covering over 1,000 gasoline trucks, it has been found that the operating expense is about 6 cents per ton mile, while for the same number of electric trucks this item becomes 7 cents per ton mile. These figures are exclusive of drivers' wages and garage expense.

Universal Joint Loss

Editor THE AUTOMOBILE:

[2,941]—What is the loss of power in the ordinary universal joint used in automobiles between the engine and the rear axle?

H. L. WOODRUFF.

Anderson, Ind.

The loss to which you refer does not ordinarily exceed 5 per cent. It will depend entirely on the angle at which the shafts are working. The greater the angle between the axes of the shafts, the greater the loss.

Tire Pointers

Editor THE AUTOMOBILE:

[2,942]—In reading through your October 19th issue I noticed a letter in which one of your subscribers asked whether letting out the clutch in turning corners saved the tires. In your answer you stated that it did, and that there were a number of other little ways in which the driver could save on tire expense. Would it be possible for me to hear from you with reference to any of the "other little ways"? I do not care how brief your information may be, as the mere suggestions will aid me considerably.

SIDNEY W. SALOMON.

New York City.

There are many other suggestions which might be offered as to the best ways of lowering tire expense, among them being to refrain from applying the brakes too hard or too suddenly, causing the tires to slip along the pavement or road and wearing them unnecessarily. Further, never run on a flat tire if possible to prevent it, as this is sure to rim-cut the shoe, often rendering it useless. Do not allow the tires to stand in oil or grease, and keep them free from rust along the beads where they come in contact with the rims. Rust eats into the rubber in a short time. Do not run in large ruts and avoid straining the shoes by hitting rough places at high speed. When drawing up to a curb, be careful not to snag the shoes against the stone.

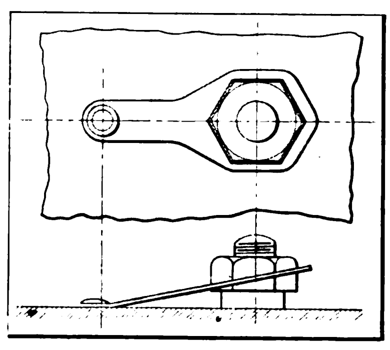

Fig. 2—A good nut-locking device

Support the Rod

Editor THE AUTOMOBILE:

[2,943]—There seems to be a good deal of play and a tendency to sag in the rod which runs from the ball-and-socket joint below the steering column to the steering knuckle arm on my car. I have tightened this rod up as much as possible but it still rattles when the car is driven. Can you suggest any means of preventing this?

J. R. DAY.

Allentown, Pa.

The thread is evidently worn, and it would be wise for you to have the rod replaced, as it is not advisable to risk any mishap to the steering gear. A leather strap support for the side-rod, as shown by Fig. 3, is sometimes used, and no doubt this would stop the rattle to which you refer, at the same time preventing the sag of the rod and the excessive wear on the thread. This strap should be fastened somewhere near the ball-and-socket joint, as shown.

Radiator Drain Cock

Editor THE AUTOMOBILE:

[2,944]—How can I get the water out of my radiator? In laying up my car for the winter I want to drain the water from the motor, but there seems to be no provision for doing this. Will you please tell me where the drain cock is usually located, as I may conclude to have one put on.

C. J. ANDREWS.

Morton, N. Y.

Most cars have a radiator drain cock located, as shown by Fig. 4, in the water outlet pipe at the bottom of the radiator. If your car is not provided with a drain of this kind, you should either fit one to the pipe yourself, or have a repairman do it for you. No car should be without such a fixture, as it is often necessary to draw off the water from the cooling system for one purpose or another.

Engine Ratings

Editor THE AUTOMOBILE:

[2,945]—As I am a subscriber to your valuable magazine, I want to ask a question to determine in my mind the different horsepowers of different bores of engines. For instance, a 3 3-4-inch by 4 1-2-inch motor is rated at 25 horsepower; one 4 1-8 inches by 4 1-2 inches is rated at 35 horsepower; one 4 inches by 4 1-2 inches at 30 horsepower, and one 4 3-8 inches by 4 1-2 inches at 45 horsepower. How can a motor jump, say, 10 horsepower on an increase of only 1-4 inch in bore? Please explain and give me the table of different bores. Do they change the gears to make this difference? If so it must kill the speed of the car.

J. A. CROUP.

Graysville, O.

The rated horsepower of a motor does not depend solely on the diameter or bore of its cylinders. There are several other factors which enter into this rating. The cylinder bore, piston travel per stroke, number of explosions per minute and the explosion pressure are all taken into account in computing the indicated horsepower of a motor. The formula used is as follows: $IHP = \frac{PLAN}{33,000}$, in which IHP is the indicated horsepower, P is the explosion pressure acting on the face of the piston, L is the length of piston stroke in feet, A is the area of the piston in square inches (which involves the cylinder diameter) and N is the number of explosions per minute (usually equal to half the number of revolutions per minute in a four-cycle engine). This is the exact method for determining the rating and it will be seen that two motors of the same bore might have widely different horsepowers. For purposes of comparison the A. L. A. M. rating for engines is usually employed. The formula adopted is $\frac{D^2N}{2.5}$. D is the cylinder bore in inches, N the number of cylinders and 2.5 a constant, based on the average view of the A. L. A. M. engineers as to a fair conservative rating for a four-cycle motor at 1,000 feet per minute piston speed. This, however, is merely comparative and in a great many cases does not come very close to the actual power of the motor. Based on this latter formula, there is a table of cylinder bores with corresponding horsepower values published by the A. L. A. M.

The gears have nothing to do with the rating of the motor.

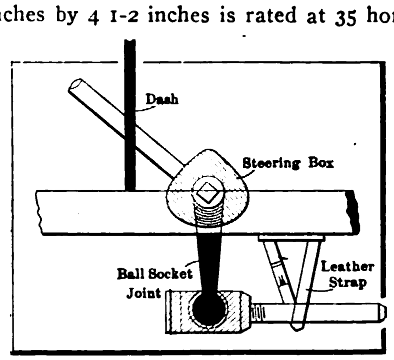

Fig. 3—Strap support for steering side-rod

Desire to Start Club

Editor THE AUTOMOBILE:

[2,946]—The automobile owners in our locality are preparing to organize a club for the purpose of bettering road conditions and erecting signs along the road for the guidance of drivers. I thought it possible that I could secure information through your columns where we could get some data as to by-laws and other matters pertaining to the formation of such an organization.

A. P. ODE.

Calmar, Iowa.

If you will address the American Automobile Association, 437 Fifth Avenue, New York City, the desired information will be gladly forwarded to you.

Care in Laying Up Cars

Editor THE AUTOMOBILE:

[2,947]—Would you kindly give me a remedy to prevent the rusting and damaging of my radiator and water cooling system while my car is out of service, as I have put it away for four months?

Wallace, W. Va. J. B. MOORE.

In laying up your car for the winter the cooling system should be drained of all the water by opening the drain-cock at the bottom of the radiator. Then the motor should be started and run for a minute or so to dry up any moisture which may still remain in the system. Of course care should be taken not to heat up the motor in doing this.

The gasoline should also be drained from the tank, and the car should be jacked up and rested on blocks or horses in a substantial manner so that the tires may be deflated to a low pressure. It is even better to remove the tires, wash them carefully, wrap them in strips of paper or cloth and store them in a dark place the temperature of which is as nearly constant at about 50 degrees as possible. If the wheels are not jacked up the tires are apt to flatten from standing too long on one spot.

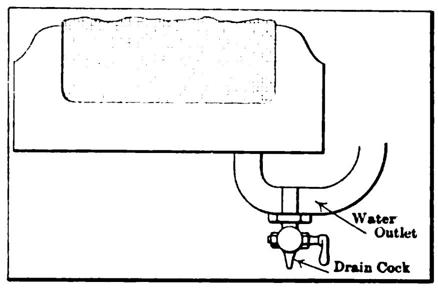

Fig. 4—Showing drain cock in water outlet

Not Very Far

Editor THE AUTOMOBILE:

[2,948]—Apropos the anti-freezing mixture discussion, how far could a four-cylinder automobile go with impunity without water in the radiator in zero weather, also in freezing weather when the temperature is about 32 degrees Fahrenheit. I am speaking, of course, relative to water-cooled cylinders.

GREENHORN.

Cleveland, O.

While we have not heard of the experiment being actually carried out, the automobile would run just long enough to allow the cylinders to get red hot, the lubricant to burn up, the pistons to seize and the wristpin bearings and others to burn up. In a word, a water-cooled motor should never be allowed to run for more than a minute or two without water circulating properly through the cooling system, if serious results are to be avoided. The high temperature within the cylinders makes it necessary to carry the excessive heat away by means of an effective circulation of water through the jackets, even in the coldest weather.

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

REMOVING GEARS FROM THEIR SHAFTS—Often it is very difficult to remove magneto or camshaft gears which are fastened to the shafts with keys, or which have been sweated on, especially if they have remained in place for a considerable length of time. Occasionally the shaft is bent, due to the force exerted when the gear is driven off from one side in the usual manner with hammer blows on the end of a rod or other tool, which, in turn, is held against the hub of the gear. A very good method for the removal of these gears is shown by Figs. 1 and 2. Two views of the tools used are shown at A and B, Fig. 1. These tools can be made of any pieces of steel which are handy, or out of an old file or two. The space between the prongs need not be over an inch to an inch and a quarter for use in connection with camshafts

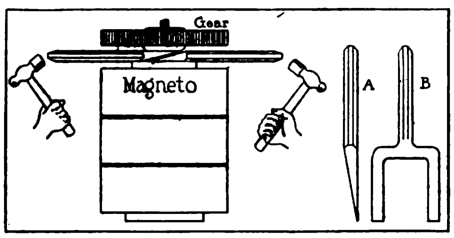

Fig. 1.—Removing magneto gear and the special tools to use

and the like. It should be wide enough to easily clear the diameter of the shaft. The prongs should be tapered from a point at the ends to about three-eighths of an inch at the thickest parts, and they should be about two inches long. For removing a magneto gear, two of these tools are used, as shown by Fig. 1. They are placed back of the gear with their tapered parts in contact, and are driven toward the center with hammers. The wedging action lifts the gear from the shaft. Fig. 2 shows the same tools being used for the removal of a camshaft gear. In this case the shaft is placed in a vise with the gear hub close to the jaws. The tools are then driven in between the tops of the vise jaws and the gear hub in the same manner as before. It should not be necessary to strike very heavy blows with the hammers, although sometimes these gears are very firmly fastened to their shafts.

FLAME PROPAGATION.—The internal expansion engine such as is used in automobiles is peculiar in that the expanding gases which drive the piston are heated directly within the cylinder. The ideal condition in any motor is to attain the highest possible mean effective pressure, this being not only true in the gas engine but in all engines which are operated by means of a cylinder or other expansion chamber. The indicated horsepower of an engine depends directly upon the mean effective pressure and, all other things being equal, will vary directly with that factor. It is not an easy matter to determine the mean effective pressure within the cylinder of a gasoline motor without an extensive apparatus, but the various conditions which affect it are well known so that in the design of the motor it can be varied to any degree required within practical limits. There are two conditions which are of the greatest importance in fixing this quantity; one of these is the compression and the other the rate of flame propagation.

The amount of compression is easily determined by the volume of piston clearance left within the cylinder after the piston has reached the highest point in its stroke or the upper dead center. The rate of flame propagation is affected by a variety of features in the construction of the engine and the condition and quality of the gas which is within the cylinder. The current theory as to the propagation of the flame in the cylinder of a gas engine is that the flame spreads in all directions at the same rate of speed through a quiescent mass of gas. This condition is approached more or less in the cylinder of a gas engine, although it cannot be ever entirely the case owing to the presence of some of the dead gases of the previous explosion in every automobile motor.

In any gas engine cylinder there is a given quantity of gas which will have to be ignited and burned, and the sooner this charge is burned in relation to the stroke of the motor the less chance there will be for any of the unburned gas to escape with the exhaust products and the sooner, in relation to the stroke, will the maximum pressure be reached. Since it takes a definite and fixed length of time to burn each similar charge within the cylinder of the gas engine, the sooner the gas is completely fired the further will it have progressed in its period of burning and expansion and the lower will be the terminal pressure. The pressure of the gases on exhausting is just so much thrown away, and hence the necessity for producing conditions which tend toward rapid combustion and flame propagation. It is for this reason that a perfect mixture is a condition which is to be desired, since either a lean or rich mixture will fire much more slowly than a perfect combination of gas and air. The mean effective pressure is governed by the position of maximum pressure of the indicator card and the pressure at exhaust, and, as is pointed out above, the sooner the maximum pressure is attained with reference to the stroke of the engine the lower will the terminal or exhaust pressure be.

The propagation of the flame is much more rapid if it is allowed to start in all directions at once, and it is for this reason that it is not good practice to have the spark concealed behind a wall or in a pocket. The rapidity of flame propagation is also affected to a great extent by the pressure of the gases. This is another point in favor of high compression, as a gas which has been compressed to the extent that is common in the automobile engine cylinder will burn very rapidly and hence will attain its maximum pressure very early in the stroke. It has not as yet been possible, however, in spite of the high compressions to attain a perfect combustion of the gasoline in the cylinder, hence a large amount of combustible material will also be found in the exhaust products.

PISTON RINGS.—As is well known, one of the greatest sources of loss of power in a motor is the leak of the compressed gas past the piston rings. This leak may be due to the fact that the cylinder is out of round,

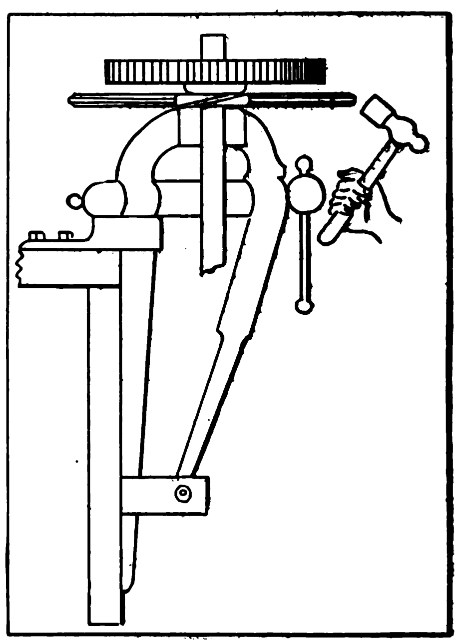

Fig. 2—A camshaft gear can be taken off in much the same manner

it may be due to the rings being worn, or to their being ill-formed or designed. In the modern motor, the rings are almost invariably of the eccentric type, that is, their thickest part is opposite to the point where they are split to admit of their being sprung over the pistons and into place. The metal is thinnest at the joints. The theory

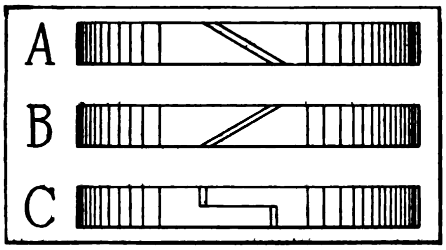

Fig. 3—Rings with lap joints are best

involved in their design so as to get the correct eccentricity is rather exhaustive, but the reason for their being made this shape is that, when the ring is in place, it will, theoretically, expand equally and exert the same force in all directions against the cylinder wall. Circular rings will not do this, but will have the greatest tendency to spread out at the point where they are split. This causes leakage, and, hence, this form of ring has almost entirely been abandoned in favor of the more correct, yet harder to make, eccentric ring.

The usual ways in which rings are split are shown by Fig. 3. At A and B are shown diagonal cuts, but the best form is seen at C. It is easier for the gas to get through the diagonal joints than the lap joint, as the angles of the latter offer more resistance to its passage.

Many motorists may think points of this kind of little importance, but if it is ever found to be necessary to replace worn or broken rings, the lap joint ring should be used in preference to the other. Much time has been devoted by automobile experts and engineers to this particular seemingly small item of design, and it is on account of just such refinements that the representative motor of to-day is as perfect and reliable as it is.

When Replacing Gaskets.—Care should be exercised in renewing worn-out gaskets so that the packing is not cut smaller in internal diameter than the holes, thus partially or wholly obstructing the passages. In cutting gaskets, the best way to go about it is to take the part which has the clear holes for the bolts or screws and support it firmly in a vise or in some other manner. Take the material from which the gaskets are to be made and lay it smoothly over the opening, where the gasket is to go, and with the ball peen of a hammer tap it lightly around the edge of this opening. This marks the rubber or other gasket material with the exact outline which the gasket is to have, and it is then a simple matter to cut the correct shape. If the gasket material is very thin, this tapping around the edge with a hammer will usually cut the desired shape immediately, and will make a very good job. In case copper or other thick material is to be used, the hammer makes the outline and the gasket can then be cut out accurately by the use of shears, chisels and punches. Gaskets made in this way are more accurate, and there is less possibility of their being out of shape so as to clog the joints.

Pipe Bender Useful.—It is often found necessary to bend a pipe so as to make it accommodate a desired space, or so that it will lead in a different direction. Pipe benders of different sizes are manufactured for the purpose, and several of them should be included in the garage equipment. Fig. 4 shows a form of bender, which is made up of a coil of wire, slightly tapered at one end so as to be readily removable after the pipe has been bent to the desired shape. The pipe is first heated so as to be easily worked, then the proper size bender is inserted in it, and the pipe bent over a form. The bender prevents the pipe from flattening out at the bend, and preserves its circular form. After the operation the bender is withdrawn and the pipe allowed to cool.

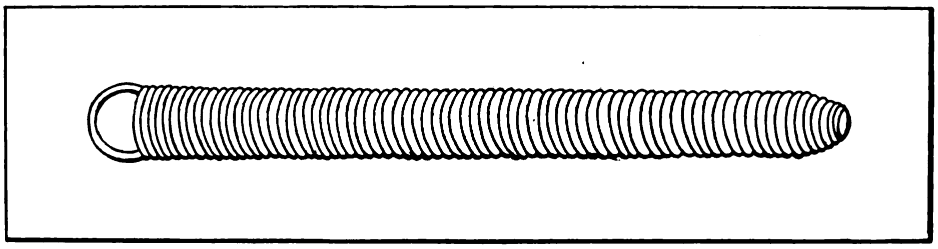

Fig. 4—Pipe benders are sometimes useful in the garage

This tool is sometimes useful in fitting manifolds and their immediate piping, also for attaching cooling-water pipes. There should be as little obstruction to the passage of the water or gas as possible, and bad bends where the pipe is flattened should be avoided, as they do not admit of free passage and increase the fluid friction.

The Cone Clutch.—Cone clutches are of two types, the internal and external. The external clutch is one in which the flywheel forms the female member and the male cone is forced into it by means of a spring or springs; this is the most common type of clutch in use to-day; it is the simplest to manipulate and the adjustments are easily made. The clutch is comparatively inexpensive and any repairs which have to be made will generally be in the nature of refacing the clutch with new leather or of simply treating the leather with which the clutch is fitted. By allowing a leather-faced clutch to slip too much, a glaze is imparted to the facing which spoils the engagement; in fact, in many cases where this glaze is excessive the clutch will either not take up at all or will take up so fiercely that the occupants of the car will be violently jerked about.

Leather can be made to give better service by applying a dressing. The leather of a clutch is the same as the leather of a shoe in that it will need occasional dressing to keep it in condition. A shoe which is never dressed soon acquires a hard, brittle condition which can only be remedied by the application of a softening compound. The dressing to be applied in the case of the leather-faced cone clutch is neat's-foot oil. The clutch leather will absorb this preparation readily at first and several applications should be given with the clutch pedal blocked out so that it is disengaged. When the leather appears to be well saturated allow the clutch to stand disengaged for the night and it will be found that in the morning the leather will have become greatly rejuvenated and regained a large amount of its lost flexibility.

With a leather-faced cone clutch easy engagement is often obtained by inserting springs beneath the surface of the leather. The springs are either of the coil type or are flat. When the coil springs are used they are generally placed on the inside of the cone and are used in connection with plungers which pass through the cone and press against the inner surface of the leather. When the flat springs are employed they are generally fitted in a recess in the metal cone beneath the surface of the leather, and when fitting the leather they are sprung. They bear constantly against the surface of the leather and lift it in spots. There are about twelve of these fitted on a 16-inch clutch.

A clutch brake is often fitted with this type of clutch so that it will be automatically applied when the pedal releasing the clutch is pressed down. This will greatly facilitate the changing of gears. It is very essential in the life of the clutch that the car should be started on the lowest speed and then gradually brought up to the highest speed so that there will be no tendency to slip.

Carry a Small Board When Touring.—Many times when on the road it is necessary to jack up a wheel for one reason or another. A small piece of 2-inch by 4-inch board about a foot long will then come in very handy to stand the jack on, especially if the road is muddy, or the ground very soft. This also serves to make the jack higher and gives it a greater height of lift.

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

A Difficult Repair

EDITOR THE AUTOMOBILE:

Perhaps some automobilists would hesitate to undertake the repair which I have shown by Fig. 1, but I did not have a great deal of trouble doing it, and perhaps some of your readers would be interested. Two of the teeth on one of the timing gears became damaged, and, as there was no repair shop handy, I made the repair as shown. The face of the wheel was dovetailed out, and then a bronze casting, B, was made, having approximately the shape of the teeth and the dovetail at the bottom. This was driven into the recess in the gear face. Next a template was made from one of the good teeth A, and the rough cast teeth B were then filed to conform with it. Holes were then drilled and tapped into these new teeth, and two set screws D were put in, the metal strip C being interposed between their heads and the gear. Of course, this repair would be harder to make if the gear were of steel in place of the softer bronze.

Lansing, Mich.

Use of Old Casings

Editor THE AUTOMOBILE:

I have been very much interested and have found many valuable suggestions in your automobile repair articles. In the issue of November 23 A. D. Hard gives some good pointers as to the use of old casings.

I have found it very hard to spring any kind of a complete casing over another one. Tears from tire-irons, especially on old casings, will inevitably occur. My method is to build up an old casing from the inside, filling in all irregularities and cleaning both casings, as suggested by Mr. Hard. Then make a copious application of cement to one-half of the inner side of the casing which is to be used outside. Kink the one to be used inside by grasping the beads with both hands and pulling outward and upward at the same time, using counter pressure with the knee. This causes the inner casing to look like an inverted bar horseshoe. While holding the inner casing kinked as described, have an assistant apply a coating of cement to the circular part and place it within the debeaded outside casing. Then carefully allow the inner casing to spring back into its original shape, at the same time working it into the outer casing. The cement can be readily applied between the uncemented portions; then, if too much of the bead has not been cut off, a remnant of it will go under the rim.

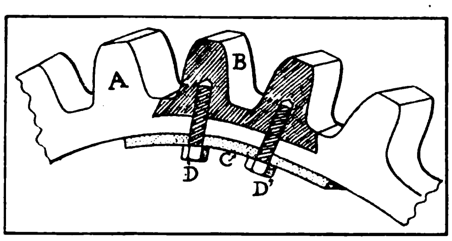

Fig. 1—Showing method of replacing damaged gear teeth

Put the casing on the wheel immediately, and apply ten pounds pressure to the tire for a half-hour. After that time, inflate the tire to its normal pressure and keep the wheel jacked up for at least 48 hours, in the meantime wiping off any exuding cement and pressing with the fingers at any places along the bead edges where there is a tendency for separation.

In all tire repair work by amateurs sufficient time is not allowed for drying before use. I have found the slow drying rubber fillings much more permanent than the quick drying ones. The first mentioned kind takes two or three days to dry, but it does not crack and makes one continuous filling, while the latter kind cracks and works out.

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

Scavenging the Cylinders

I have another hobby. I always descend hills with the clutch in the desired speed and the batteries off, thus allowing a full charge of gas to circulate through the engine and muffler. This cools the engine, cleans the combustion chambers and exhaust valves and softens up the carbon in the muffler.

If the spark is well advanced and the throttle opened wide on an immediately succeeding level stretch most of the carbon will be burned out of the muffler.

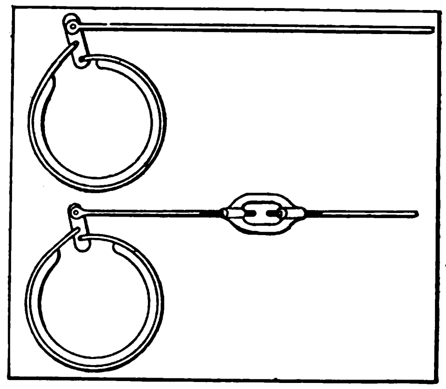

Fig. 2—Turnbuckles are easily attached to the brake-rods

I also invariably speed up my engine on stopping, even if I do not intend to start on compression. This forces all dead gases out of the cylinders, since by throwing the gears into the neutral and shutting off the engine the flywheel turns it over and forces new gas into the cylinders. Dead gas, standing, will usually precipitate solid carbon.

"MOTOR WOULD-BE-WISE."

Plymouth, Pa.

Put on Turnbuckles

Editor THE AUTOMOBILE:

I have an old car which formerly did not have provision for the adjustment of the brake-rod tension. I decided to put turnbuckles on these rods, as shown by Fig. 2. I cut the rods in two at the middle with a hacksaw, then took out about an inch of each rod, so as to allow for the adjustment. A thread cutting die was then procured and a male thread cut on one end and a female thread on the other. I then had two turnbuckles cast, and the same number of threads cut in them as on the rods. After applying them to the rods I found, of course, that the efficiency of my brakes was very much increased.

Dubuque, Ia. C. P. ROGERS.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Rather Dreamy

EDITOR THE AUTOMOBILE:

My conception of a modern motor car will certainly come in the class of "ideal," but the mark of 1912 will hardly apply, as it is rather doubtful if my car will be on the road before 1915.

The motor of this car will be of six cylinders cast in pairs, operating on a two-part cycle. The crankshaft is carried on four large plain bearings and is drilled for lubrication under pump pressure. Two fly-wheels will be used, both of small diameter so as to allow the motor to be set very low in the frame and still have ample clearance. The rear fly wheel will house a dry plate clutch consisting of a small number of large size plates, each pair of which is separated by a friction member which takes the wear and is easily renewed. The front fly wheel is not attached direct to the crankshaft, but is driven through a multiple disc clutch held in engagement by a spring of such strength that at certain engine speed a slight slippage will occur which will dampen the periodic vibrations common in most six cylinder motors.

Each cylinder is of the two piston design, the upper power cylinder having a bore of four inches and a stroke of six inches. The lower charging cylinder is of such size as to have a volume slightly in excess of the power cylinder and connecting passage. Pure air only is drawn into the charging cylinder from the crankcase. This tends to muffle the noise of air induction, produces a slight vacuum in the crankcase which prevents oil leakage, heats the air slightly and charges the air with an oil mist which will be sufficient lubrication for the charging cylinder. The compressed air charge is conducted to the adjacent power cylinder of the pair through a combined rotary valve and passage way. One valve is used for each cylinder, two being placed in each block on opposite sides between the cylinders. These valves are operated through worm gears by two secondary shafts driven by a single silent chain from the crankshaft. The upper end of each valve extends through the top of the cylinder casting and carries a cam which operates the fuel pump atomizer for that cylinder. The strokes of these pumps are adjustable from zero to maximum, and are controlled the same as with the usual throttle. The ignition system is double throughout, except the dynamo, and both operate all the time. The dynamo, which also supplies current for the car lights, is driven by silent chain from the rear end of one of the secondary shafts. Current is kept constant by means of a governor which instead of controlling the speed of the armature controls its position in the field. As the speed of the motor changes, the armature is shifted in and out of the field. When the motor is stopped this governor automatically switches on the current from the storage battery to supply the lights.

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

The cooling of this motor is through a new type of radiator carried on the dashboard, the hood of this car being of the Renault, or, more properly, the Franklin type, as there is no radiator visible from the outside. By means of a mercury pressure regulator, the temperature of the cooling water runs to about 300 degrees before boiling, which adds greatly to the efficiency of the engine. Water circulation is by a thermo gravity system, as the bottom of the radiator is well above the bottom of the water jackets.

The excess compressed air is carried in a tank and used for starting the motor and inflating tires. The gear box is carried on the rear axle and is "nearly gearless," as only two gear sets are furnished, one for reverse and one extra low for extra hard pulls, starting on direct drive being possible with this flexible motor.

Brakes are of the multiple disc type, carried in the rear wheel brake drums, and operated by the two foot pedals. No brake lever is used and the speed change lever is carried in the center of the car.

The wheelbase of this car will be about 120 inches, with tires 36 x 5.

Any standard body will be fitted to suit the user.

Accessibility, ease of replacing wearing parts, comfort for the passengers, noiselessness and high motor efficiency are points striven for in this ideal car.

GUESSER.

Brocton, Ill.

Desires Interchangeable Body

Editor THE AUTOMOBILE:

In my opinion, the ideal automobile for 1912 would be a six-cylinder, 40 horsepower car, weighing about 3200 pounds, and fully equipped with top, lamps, tools, horn, baggage rack, tire irons, speedometer and clock.

The motor would be either of the valveless type or it would have valves in the head, with the valve-springs enclosed. The carbureter would be of the double-jet type with an auxiliary air valve, adjustable from the seat. The cooling system would consist of a cellular radiator of ample size, gear-driven pump and gear-driven fan. Ignition would be by means of a storage battery and Bosch magneto with two sets of spark-plugs. The splash system of lubrication with auxiliary force-feed to the crankcase would be used. The transmission would be of the selective type, four speeds forward and reverse, with direct drive on high. Shaft drive with bevel gear would be used, and I would have both internal expanding and external contracting brakes on the rear hubs. I would want the brake-bands so arranged as to be readily adjustable and all parts of the braking mechanism accessible.

As for the body, it would be arranged with the driver's seat on the right. Several bodies would be part of the equipment, and they would be made to fit the same chassis, so that touring car, roadster, phaeton, limousine, coupé or landaulet could be used as desired.

The wheels would be made for 36-inch by 4½-inch tires, and the rims would be quick detachable. The springs would be semi-elliptic, and there would be shock-absorbers attached. I would want a B. & L. Castor front axle, so as to make driving easier and safer. The steering gear would be irreversible, of the worm and sector type.

This car would not be very expensive, if made in sufficient quantity.

F. G. ENSON.

Newburgh, N. Y.

Specifies Two Mufflers.

Editor THE AUTOMOBILE:

My idea of a 1912 automobile is as follows: Knight motor, bore 2½ inches, stroke 7 inches, four cylinders, underslung frame, 122-inch wheelbase, 38-inch by 4-inch tires, four speeds ahead, four-passenger body with plenty of room in the tonneau, full floating axle, 20-inch by 2½-inch brakes, tires carried under the back seat. I would also have two mufflers, one alone to be used in the country and the two together where absolute silence would be desired.

SHERMAN FAIRCHILD.

Oneonta, N. Y.

Automobile Metallurgy Made Easy

By E. F. Lake

Part III

Elongation and Reduction of Area

(Next Week—Torsional Strain)

ELONGATION, which is sometimes called extension, and reduction of area, which is sometimes called contraction, are also important factors that are shown by the tensile testing machine.

When a test bar is pulled until it is broken, it stretches or elongates. This elongation is always given in percentage. A certain gauge length is taken as a unit. The distance that the specimen stretches beyond this, from the time pulling is started until the break occurs, is figured as the percentage of this unit, and this is called the percentage of elongation. The elongation up to the elastic limit is very slight in most metal and does not indicate any particular property of importance; it is also difficult to obtain. Two inches on the length of a test bar has generally been accepted as the unit from which to figure the percentage of elongation for automobile materials. For some other uses, and in some other places, 8 inches has been standardized as the unit.

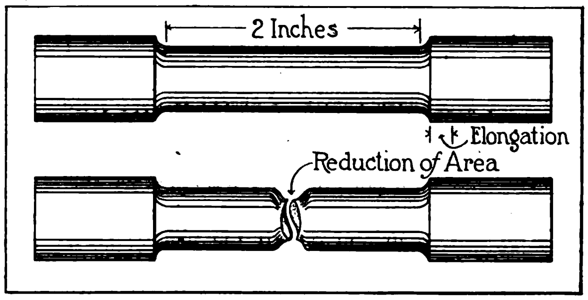

Fig. 1—Test bar before and after it was pulled apart

Elongation gives an idea of the plasticity and ductility of metals. While these are properties that may be beneficial in some places and for some kinds of work, they have very little place in automobile construction, unless it be for bearings or in places that require very little strength or stiffness. As plastic means softness in metals, those that are plastic are easily forced out of shape and they would have a high percentage of elongation. Ductility means that metals can be easily drawn or twisted and thus forced out of shape, whereas stiffness is what is required of nearly all automobile parts.

A certain amount of elongation is necessary, however, as this would indicate properties that overcome brittleness. As a rule, the greater the percentage of elongation, the less will be the brittleness, and vice versa. For instance, high carbon steel that has been hardened in water or brine, would have hardly any elongation and be so brittle it could easily be broken by a sharp blow. Such steel might even have a very high tensile strength and elastic limit, but as there is no give to the metal when the blow is struck, it is fractured, being a great deal like glass. If the same steel were thoroughly annealed, or softened, it would have a comparatively high percentage of elongation with very little brittleness and thus be very difficult to break.

For most parts of the car, therefore, it is necessary to have some elongation in the metals, but this elongation does not want to be anywhere near that shown by a rubber band. If it were the metal would be practically useless. Elongation is the least important of the four properties shown by the tensile machine. On account of the elongation shown by such materials as rubber, many metallurgists are claiming that it should be ignored when testing steels and reduction of area or contraction be made the real important property of these two.

Reduction of area is a phenomenon that always accompanies elongation. In pulling test bars they do not elongate throughout the whole distance of even the 2-inch length that the percentage is figured from, but the stretching is confined to a small space. Nothing is added to the volume of metal as the specimen is stretched and consequently its original diameter is reduced. The cohesive force, which binds the molecules together, causes them to flow toward the center of the test bar and reduce it in diameter while it is being stretched out lengthwise. The shape that these test bars take at the break is shown in Fig. 1. This shape varies considerably, however, as some metals might elongate considerably and not contract very much; others might contract a great deal and not elongate very much.

The cohesive force varies considerably in different metals or alloys and hence there is no uniform ratio between the elongation and the reduction of area. For instance, a large elongation over a short distance in the specimens length, might only show a comparatively small reduction of area owing to the cohesive force not drawing the molecules as closely together as it would in other specimens, or other metals.

This contraction or reduction of area is also figured in percentage. The area across the original test bar before breaking is taken as the unit on which to figure this percentage. The amount that this area has been reduced, at the point of breakage, is then figured as the percentage of this unit, or the percentage of the reduction of area.

The reduction of area shows the toughness, density, hardness and cohesion of metals and, therefore, is a very important factor in judging their mechanical properties. In fact it is one of the most important of the four properties shown by the tensile machine. If the figures for the elastic limit and the reduction of area can both be made high in one piece of metal, it is the ideal condition to attain. As an instance of this, one gear maker said, "An ideal carbon steel for transmission gears is one that would have 85,000 pounds elastic limit, with a reduction of area of 45 per cent." Either one of these figures is easy to obtain in these steels, but it is difficult to find a brand or to so work it mechanically and heat treat it that both figures will be obtained.

Heat treatment affects the percentage of elongation and reduc-

EFFECT OF HEAT TREATMENT ON ELONGATION AND CONTRACTION

Heat-Treatment.	Percentage of	
	Elongation.	Reduction of Area.
Annealed at 1475° F.	29	59

	20	68
	21	66

tion of area, as well as the tensile strength and elastic limit. It affects these, however, in diametrically opposite directions. That is to say, when steels are hardened, their tensile strength and reduction of area are raised. Then the metal is very hard and shows a high strength when given a straight pull. The low figures for elongation and reduction of area show that the metal has lost nearly all of its plasticity and ductility as well as its toughness and density. It would, therefore, break easily if given a sharp blow or if bent, or twisted. By drawing this hardness, as in tempering, the percentage of elongation and reduction of area is raised, bringing back some of the ductility and toughness, while the tensile strength and elastic limit are lowered, thereby reducing strength in that direction.

The effect of heat treatment on the elongation and contraction of a nickel steel is shown in the table. The action on the tensile strength and elastic limit was given in my preceding article entitled Elastic Limit. Pieces that go into the various parts of an automobile must be heat treated in a manner that will make them withstand strains. Almost all the pieces are treated differently in this regard as their work is different.

Glycerine in Steel Treatment

Intermediate grades in the hardening of steel, especially tools, are difficult to control, as oil does not mix with water and the method of floating a layer of oil on top of the quenching bath gives indifferent results, while quick dipping in oil followed by complete cooling in water requires considerable skill and does not always produce the results aimed for. In practice the degree of hardness imparted to the cutting edge of a tool is either that produced, in the grade of steel used, by quenching in oil or that produced by quenching in water. Higher degrees of hardness may be produced by using brine and by other well-known means, but the considerable range of variations in hardness while lies between oil and water quenching is not under effective control. The use of several different kinds of oil, such as rape seed and fish oil, of different fluidity and conductivity, is a complication in the ordinary shop, and cooling by air-blasts of varying intensity is applicable to high-speed steels only. In this situation, the use of glycerine instead of oil recommends itself, as it is miscible with water in all percentages and also readily receives those admixtures of salt and acids which may be desirable for graduating the hardening effect of the bath. And this substance has been found to impart to the bath exactly the same qualities which characterize oil. It softens the temper and obviates distortion of the hardened article.

While no formulas good for all requirements can be given, anybody familiar with hardening work can readily find for himself the admixture of glycerine which suits his special purposes, just because the admixture may be made in any desired percentage. Guiding examples may be offered, however. For a medium average hardness, a bath as the following may be found suitable to start with: Glycerine, 8 kilograms; water, 10 kilograms; cooking salt, 1-2 kilogram; sal-ammoniac, 100 grammes; concentrated hydrochloric (muriatic) acid, 50 grammes. And for a bath producing sharp hardening 66 weight parts of glycerine with 100 parts of water, 18 of sal-ammoniac, 24 of cooking salt and 2 of alum may be tried. The baths should always be stirred before first using, to make sure of uniformity.—From *Metall-Technik*, October 14.

Frosted Carriage Windows—In the winter the windows of a closed automobile draw moisture from the respiration of the occupants and easily freeze up or at least become clouded with vapor. Two simple ventilators, one in each upper corner of the vehicle, to the rear, reduce this annoyance and cause no drafts.—From *La Pratique Automobile*, Nov. 10.

It is mentioned in *The Auto* (London) of November 18 that "Antimist" is a preparation supplied by Dunhill's for the same trouble, with special reference to windscreens and goggles. It is a waxy substance put up in the form of a pencil, which is rubbed on the glass. The latter when polished regains complete transparency, but sheds mist.

Nobody Hurt

ONE of the best features connected with the running of the grand prize, the Vanderbilt, the Savannah and the Tiedeman races last week at Savannah was the fact that nobody was bodily injured during the actual running of these races. This pleased every spectator around the circuit. There may have been those who went to the races with the hope of seeing a car upset at a curve or run through a fence, but they went home better pleased at seeing everything go off well. This fact was commented on in every quarter after the completion of the races. True, there were a couple of serious accidents during practice, one of which resulted fatally and the other in the serious injury to one or two persons and in the damaging of several cars. That accident in which a driver was killed was not due to the course or to anybody on the course. It appears that the car was going too fast out of a double turn and could not be held on the road. The other accident was due to touring cars on the course during practice.

The question was asked several times at Savannah how it was that no one was injured out of the forty-six starters in four different races. There are several explanations: In the first place the drivers with fast cars were nearly all, in fact, all seasoned drivers, drivers who know automatically when a left or right rear tire explodes, which one it is without having to turn round and look or have the mechanic look, and drivers who know automatically and instantly what to do in case of tire trouble. These are the two great reasons why Savannah was free from accidents. There were plenty of tire explosions—they took place on every lap. Some of the drivers averaged a tire change every other lap for the twenty-four circuits of the grand prize race and yet they were not once in the ditch. The only answer was that they were seasoned drivers. At nearly all of the other big races this year there have been a number of names comparatively new in road racing and an analysis will show that in the majority of cases the accidents have happened to these novices. In the majority of cases the accidents have been due to tire explosions. Because of this fact it appears to be more imperative that the drivers before being granted a license to drive in a track race, a road race, a beach race or a hill-climb, be subjected to a tire explosion test. They should be compelled to drive on a broad straightaway and have one of the rear tires exploded at high speeds in order to ascertain, first, if the driver can tell by the movements of his car which tire has exploded and also, if he can properly control his machine. The distance that his car swerves to the right or left should be measured and if it exceeds one-half the width of a road, as used for road races, an accident would likely result and the driver should be refused a racing license.

After a series of big races is the proper time to learn the lessons that are, or should be, enforced at succeeding races. The only accident that resulted fatally at the Savannah races took place during the first day of practice. The driver was taking the turns too fast before he was familiar with them. This suggests that every precaution should be taken on the first day or so of practice. That perhaps only half of the cars should be allowed on the course at once and that each driver should be cautioned against fast driving. Much of the fast driving in early practice is done for advertising purposes. The driver wants to get a little credit in practice; he may think that he will not have much chance in the race. Often the team manager is very close to the ears of some newspaper reporter and wants to get it all over the land that his car has made such-and-such time in practice. There is always a reason. Quite often the time for practice is short and the driver really has to try out his different speed ratios in order to study how to take the turns.

The Savannah Automobile Club, the citizens of Savannah and the soldiers deserve hearty congratulations on the conduct of the races. The course was kept clear from start to finish and the public was well safeguarded by safety fences, by keeping them back from the turns and by guarding all of the dangerous places on the course. The soldiers again demonstrated the fact that they are equal to any emergency, and with such a corps of soldiers it would be possible to keep a course equally clear in the heart of Long Island or in Westchester county, New York. Keeping road race courses clear is simply a matter of purpose. When the purpose is there the rest is easy. It means getting the troops on the ground early and taking possession before the crowds get there. In guarding a course an ounce of prevention accomplishes more than a ton of cure. It would take a big army to clear a course after the mob had positioned its cars all over on it and after the masses had taken up positions that they would have to leave.

The recent series of Savannah races further demonstrated the fact that a 17.14-mile course is too long and that a 10-mile one would be much more preferable, particularly with small fields of cars, such as at present, when not over sixteen compete in one race. At Savannah there were frequently 3- and 4-minute waits and during these the interest of the crowd waned, and as some expressed it, "They forgot that there was a race on." The 10-mile course with a wider roadway is better for holding the interest of an audience than a longer course, particularly during the last half of a race.

Harmony Reigns at A. A. A. Meeting

GREATEST in size and importance of any of the annual meetings of the American Automobile Association is the one held Tuesday at the Astor in New York City. Almost 100 delegates responded to their names at the preliminary roll call and practically all the clubs identified with the national organization were represented either by an officer or by proxy. There had been rumors of dissensions that were scheduled to break out during the meeting but aside from one ineffectual flare the proceedings moved along with harmony and precision.

Vice-president Bonifield, backed by a numerous Ohio delegation and with some scattering support from other states, was supposed to be the leader of the opposition, but when it came to actual proceedings the trouble did not materialize.

The contention was that a resolution introduced at the last meeting by Dr. Bonifield and adopted by the association provided for holding the next annual meeting in the Middle West. Such an entry was not found upon the minutes and Dr. Bonifield and his supporters prepared to have the minutes changed to show such action. The proposed changes were defeated by a vote of 4 to 1 and Dr. Bonifield was given permission to file two affidavits tending to support his contention that such a motion had been made at the last meeting.

When the delegates finally came together on a friendly footing it was explained that the resolution introduced by Dr. Bonifield last year had been held up pending an opinion as to the legality of the plan to hold the annual meeting of the association outside of New York. This opinion was adverse under the existing condition of the association's charter. A change in the charter was thereupon advised, placing the power to fix meeting places anywhere in the country in the province of the Executive Committee.

The meeting then heard the reading of reports covering its work during the past year. President Hooper covered the whole field generally in his report and was followed by Chairman Terry of the Legislative Board who recounted the work of getting good laws upon the statute books and preventing bad ones from being enacted. He dwelt upon the influence of the association in standardizing state laws to their present status and spoke at some length as to the chances of federal legislation. He declared that the federal registration bill only needed one more determined effort to place it upon the book of national laws. He emphasized the necessity for such a law, even with the contingency of general reciprocity.

Chairman Diehl of the Good Roads Board outlined briefly the activities of his committee, paying particular attention to the assistance that had been given the work by the National Association of Automobile Manufacturers. He subscribed to the report of Chairman Terry with respect to Federal registration and applied it to the cause of federal aid in road building.

Chairman Longstreth of the Touring Board told of the extensive map work that had been done under his direction and Chairman Schimpf of the Contest Board presented a summary of the contest work of the year. Among the figures given out by Mr. Schimpf were the receipt of over $10,000 for sanction fees; $1,000 for driving licenses; $7,000 for stock car certificates and the expenditures of his department. His report showed a balance on hand of $57.

Powell Evans also made an interesting report on international relations in which he discountenanced further attempts to make foreign maps for use in touring abroad. He called attention to the fact that the Michelin Tire Co. distributed free many thousands of interesting maps and road directions for use in foreign countries and warned the assembly that unless the A. A. A. did something toward getting out books on American roads for use of foreign tourists, the tire concern would certainly forestall the association in that field also.

Horace A. Bonnell, treasurer of A. A. A., presented the last of the general reports when he read the balance sheet covering the finances of the year. According to Mr. Bonnell's report, the receipts for the year were about $35,000 and that sum together with $9,000 on hand, at the beginning of the period, constituted the treasury of the A. A. A. Against this sum there were expenditures of about $41,000, leaving a balance in the treasury of about $3,000.

The expenditures covered salaries, the largest item; expenses of various sorts and subscription to the *American Motorist* of $6,700. The receipts showed a subscription of $5,000 by the N. A. A. M. and the payment of Contest Board bills by the M. C. A. amounting to about $2,800.

In the afternoon there were a number of addresses and discussions detailing the work shown in the annual reports. Tuesday night the association enjoyed its annual banquet, the largest and best attended function of its kind in the history of the association.

The following officers were nominated and elected: Robert P. Hooper, Pennsylvania, president; Frank M. Joyce, Minnesota, first vice-president; Laurens Enos, New York, second vice-president; C. L. Bonifield, Ohio, third vice-president; Ralph W. Smith, Colorado, fourth vice-president; F. L. Baker, California, fifth vice-president; A. G. Batchelder, New York, chairman executive committee; H. A. Bonnell, New Jersey, treasurer; John N. Brooks, Connecticut, secretary. Executive committee: L. R. Speare, F. G. Staples, Frank G. Webb, H. L. Vail, P. J. Walker, H. E. Coffin, Frank M. Joyce, J. G. Weeks, E. C. Smith, A. H. Knoll, J. H. Edwards, Dr. A. P. Overgaard, H. J. Clark, G. M. Robinson, John A. Wilson, David Beecroft, John N. Brooks, Powell Evans, P. M. Milner, J. P. Coghlin, Paul C. Wolff, James T. Drought, S. A. Miles, F. C. Battey, Charles E. Doe, Edwin S. George, H. A. Bonnell, H. C. Peck, H. B. Race, W. E. Moyer, H. M. Rowe, S. D. Capen, H. L. Gordon, W. M. Stevenson, Oliver Quayle, W. E. Metzger, C. H. Verschoyle and Preston Belvin.

Chairmen of boards: C. T. Terry, legislative; George C. Diehl, good roads; Howard Longstreth, touring information, and William Schimpf, contest board.

The annual banquet was presided over by President Hooper as toastmaster. Among the speakers were: L. R. Speare, C. T. Terry, C. P. Chase, H. L. Vail, Alfred Reeves, A. L. Pope and A. G. Batchelder.

The association will meet probably at some point in the Middle West at its next convention. In the report of President Hooper a further amendment of the constitution was recommended empowering the executive committee to name the place, but it is doubtful whether the constitution of the association can be amended in time to allow that clause to become effective this year. The recent amendment allows the meetings to be held in cities outside of New York at the will of the association.

The whole convention was most harmonious and the get-together spirit was apparent in every move that was made. After the little storm cloud that threatened the opening of the convention had been dissipated, the program was carried out with much speed and accuracy. The general opinion that prevailed among the delegates was most optimistic as to the future of the association.

Owing to the fact that the routine matters of the association were completed with celerity, it was found to be unnecessary to hold any sessions after Tuesday night and consequently the subsequent meetings scheduled were declared off.

Members of the Society of Automobile Engineers Visiting the Panhard-Levassor Factory in Paris

S. A. E. on French Factory Visit

PARIS, Nov. 28—Scattered somewhat at the close of the English trip, the members of the Society of Automobile Engineers rallied in Paris, and, reinforced by some of the officials of the British Institution of Automobile Engineers, entered the Panhard-Levassor factory in an imposing group. This visit doubtless united a greater number of members than any previous one, and in view of the large amount of sight-seeing done during the previous week, and the many and varied outside attractions of Paris, spoke well for the enthusiasm of the members in following up the primary object of the trip.

Although there was not the same intimate relationship between the heads of the factory and the visitors as on some of the English visits, the directors evidently preferring to keep in the background rather than face the language difficulty, the Panhard-Levassor Company threw open every department of the factory and placed competent guides at the disposition of the visitors. The interest taken in this pioneer French factory was manifest in the difficulty in getting the members through the various departments; the megaphone man had to be very much on the job. With a staff of 2,300 men, the Panhard-Levassor Company produce a car a man per year; more of the car, however, is built by the factory than is usual in French concerns, the Panhard-Levassor Company making all its own castings with the exception of aluminum die casting, building its own wheels, and making most of the accessories except the magneto.

Knight motors were much in evidence, the sleeve valve engine now being employed on 50 per cent. of the chassis produced in this factory. As the total output includes a number of trucks, the Knight is in a considerable majority on the touring car chassis. Wood working machinery was the original business of the Panhard-Levassor Company, and although this has been considerably outgrown by the automobile work, it is still an important section. It is in consequence of the production of wood working machinery that the firm builds all its own wheels, contrary to the general practice in France. Hickory being difficult to obtain in Europe, acacia wood is employed for the spokes, ash generally being used for the rims. The wire wheel has only just been received into favor at this factory, and although it will be fitted on request, is not made a standard feature.

The efforts made by this company to assure a good supply of skilled labor were noted with interest. Owing to compulsory military service robbing every man of 2 years of his life, it is difficult to get youths to go through the usual period of apprenticeship. In consequence a special apprenticeship workshop is maintained, where, under the instruction of skilled mechanics, youths are put through a 3-years' course in practical and theoretical mechanics. During the 3 years nominal wages are earned, and on the completion of the term the youths pass into the main factory, eventually becoming shop foremen and draughtsmen, in the majority of cases. This system has the advantage under the factory laws of allowing the shops to work overtime and night shifts. Where youths and women are present, overtime is not legally allowed.

While the main party visited the Panhard-Levassor works, a small group of members went through the Bayard-Clement factory. These works more closely approach the American standard of organization and operation than any other in France, for they were completely built at one period, not having grown up from year to year, and are fitted with a large amount of American and other automatic machinery. More than any other, Clement has attempted to reduce the cost of production by reason of economic factory organization, automatic machinery, and a reduction in the number of models. A feature is made of completely equipped cars, the body work being done on the premises, only the specially high-class work being done outside. The Clement-Bayard Company possesses its own foundries and a supplementary factory at Mezières, in the French Ardennes, and it is there that all the castings are done and a certain amount of machining carried out; this has the natural tendency to make the Paris factory more in the nature of an erecting shop.

This firm is unique in being the only one to devote itself to the production of aeroplanes and airships. Working at first in conjunction with a balloon maker, the company has gradually extended the scope of its work until the complete airship is now built on the premises. The nacelle is an all-metal construction that can readily be undertaken in an automobile factory; the motors used in airships are mostly of the four-cylinder vertical type, with a cylinder bore of from 6 to 7 inches, and the fitting has much in common with the automobile practice now in vogue.

Recently a section of the factory has been set aside for the construction of gas bags thus making the firm entirely independent of outside assistance. After being assembled and tested, the practice is to dismount the airships and transport them to the aerodrome at Compiegne, about 40 miles away, where assembly takes place and the trial flights are carried out. This aerodrome is without doubt the finest in the world, the balloon sheds being magnificent structures of steel and galvanized iron with cork lining, having special heating arrangements, electric light, wireless telegraphy installation, special workshops, and a large hydrogen producing plant.

While the main party occupied the afternoon of the first day's visit to Paris in inspecting the Lemoine factory, devoted to the production of axles and automobile springs, a smaller group was received at the Renault works, the largest in Europe devoted exclusively to automobile production and having an annual output of 6,500 cars. Very extensive additions are being made at the present moment to the Renault factory with a view to extensions in the truck line, and in order to enable the firm to make its own aluminum castings. At present all cylinder castings are made on the premises. At the close of the visit to the factory the members of the party spent an interesting half hour in conversation with Louis Renault, recognized as one of the most skilled engineers in Europe. Conversation naturally turned to the American invasion.

Louis Renault regretted that conditions were such in Europe that no manufacturer was able to devote himself exclusively to one or two models. In order to meet all requirements his factory was obliged to produce twenty different types; the European demand was not sufficiently great to allow any manufacturer to devote himself exclusively to one model.

He expressed it as his opinion that the less expensive grades of American cars would not get a permanent hold of the European market, but if they should do so he was convinced that the French government would remove the anomaly of a 25 per cent. duty on American imports into France, and a 50 per cent. duty on French cars going into the United States. For trucks carrying 2, 3 and 5 ton loads, Louis Renault gave it as his opinion that the use of rubber tires would have to be abandoned on account of cost. This was particularly the case in France where they had to compete with horse traction and cheap labor. The price paid for carrying a ton load anywhere within a 7-mile radius of the city of Paris was only 60 cents on horse-drawn vehicles, and in order to get down to this low figure with automobiles, it was necessary that tire maintenance should be abolished entirely. Renault has made a move in this direction by building 3 and 5 ton trucks fitted with steel tires, and is so convinced of their greater economy, that he recommends them in preference to rubber shod trucks.

To give an insight into the development of the aeroplane industry in France, a visit of inspection was paid to the Esnault-Pelterie factory at Billancourt, where Rep monoplanes and motors are built. The firm is occupied almost exclusively on military work, and produces an all-metal monoplane of unusual strength. Steel tubing is employed throughout for the fuselage of the machines, the entire front portion being encased with sheet aluminum, and the rear covered with rubbered cloth. The wings are the only portion of the aeroplane in which wood is employed. All the motors are built on the premises; they are five-cylinder type, air cooled, with valves in the head operated by a single overhead rocker arm. Three connecting rods are received on one pin of the two-throw crankshaft, and two on the other; the shaft is bored and has forced feed lubrication. An interesting mechanical construction was the fitting of the carbureter in the oil sump of the crankchamber in order to assure an even temperature in all weather conditions. The float chamber was outside and at the base of the motor, with the jet within the base and the intake pipe running right across the oil tank, then passing outside to a circular distributor from which the five cylinders were fed. The original intention was to pay a visit to the Rep aerodrome at Buc, but as weather conditions made flights impossible, this visit was abandoned.

Louis Delage, one of the leading French light car manufacturers threw open his works to the American engineers, and a number of the members of the party availed themselves of the opportunity of inspecting them.. This factory is one of comparatively recent origin, having been established 5 years ago with the object of building what is known as voiturettes. Single cylinder models only were produced at the commencement, but these were later driven out by four-cylinder cars, and the output now consists of two models only, a four-cylinder of 75 by 120, and a six-cylinder of 65 by 125 mm. bore and stroke; the present output is 1,000 cars per year. Delage was the winner of the last light car race held during the past season in France, under the 3 litre cylinder volume rule.

As a fitting close to the European trip, André Michelin entertained the members of the Society of Automobile Engineers with a dinner at the Automobile Club of France on the last day of the official visit. André Michelin, in rising to propose the toast of the President of the Sister Republic, stated that he knew 24 English words, and as seven of them were not fit to print, he believed it would not be possible to make a speech with the remaining 17. He, therefore, asked them to allow him to greet them in his own language, leaving it to his brother-in-law, Mark Wolff, to translate that greeting into English. In drinking to the success of the American automobile industry, Mark Wolff, director of the Michelin Tire Company, of London, hoped to see more and more American automobilists in Europe, and assured them that they would always find the touring organization of the Michelin company at their disposition.

Mr. Havvette-Michelin, manager of the Michelin factory at Milltown, N. J., thanked the Society of Automobile Engineers for the honor they had done them in accepting their invitation and expressed the belief that such gatherings would do much to strengthen the bonds which united the industries of America to France.

Howard. E. Coffin replied in the name of the American engineers and retraced the growth of the Michelin company from the earliest days to the present time with its establishments in four countries and its staff of 15,000 workers. The evening closed with a concert given by some of the most brilliant artistes of the opera and the Opera-Comique, and by a set of dances performed by Mlles. Chasles and Meunier of the Paris Opera house.

Although the official program of visits in France was not as elaborate as that drawn up for England, small groups and individual members of the party visited numerous other factories. A small number, too, extended their investigations to Germany.

Revival of Paris Annual Show

Finding the center of the European automobile market slipping away from Paris, in favor of London, Berlin and Brussels, the French Association of Automobile Manufacturers, presided over by Marquis de Dion, is determined that the annual automobile salon at the Grand Palais in Paris shall be revived and that the income from it shall be distributed among the exhibitors, so as to reduce the cost of staging the great show, rather than turning the profits into the treasury of the Automobile Club de France, whose leading men, René de Knyff and Louis Renault, "under the placid presidency of Armand Peugeot," are charged with the responsibility for having weakened the position of the French industry by first rendering the cost of the annual show prohibitive, for the benefit of the club, and afterward abolishing it; all for the selfish motive of preventing small and progressive manufacturers from making themselves conspicuous before the public and establishing a competition with the big and prosperous concerns which the leaders in the club represent. "The fight between the two factions is on, and soon the columns of the automobile press will reverberate with the echoes of the battle," says *L'Automobile Belge*, November 10.

Starting from Savannah in the tour around Georgia

Bell's Ferry across the Altamaha Ferry, outside of Toxley, Ga.

Georgia Tour Proves Hard Ride

ATLANTA, GA., Dec. 4—Slightly the worse for chilling breezes and dusty roads, but not otherwise disfigured, the Tour Around Georgia rolled smoothly into Atlanta Saturday afternoon and completed the second annual run around the Empire State of the South.

This tour left Atlanta, for an eleven-day trip on the morning of Wednesday, Nov. 22. It arrived at Savannah Saturday afternoon, Nov. 25. All of the tourists spent Sunday in Savannah and Monday at the race course, watching the running of the Vanderbilt. Then five cars, with W. B. Stovall, of Atlanta, acting as pacemaker in his Cole 30, checked out Monday morning at 8.30 and continued on a sort of informal jaunt to Atlanta. Those in this party included No. 57, Cole 30, W. B. Stovall, acting pacemaker; No. 40, Chalmers, Sheriff F. G. Edwards, of Dougherty County; No. 30, Buick, C. A. Holmes; No. 28, Cadillac, C. A. Fuller; No. 32, Buick, C. A. Thatcher.

These cars got away in the midst of a most depressing rain but once out of Savannah they met better roads and from that point forward found reasonably good going. Their trip to Atlanta was without special incident and they checked out, after a two-day run Wednesday night, Nov. 29.

The main body of the tourists waited for the running of the Grand Prize race, on Thanksgiving Day, and did not desert the scene of action until the very last gun had been fired.

This main body checked out of Savannah Friday morning, Dec. 1, with the coldest weather of the coldest early winter Georgia has ever known, making things generally unpleasant. Nor was the road from Savannah to Dublin, the night stop, any material improvement over the weather. It was frosty and bumpy going most of the day, with just enough warmth toward noon and just enough good going by spells to keep up the courage of the contestants.

Friday's run saw another perfect score go by the board, which was remarkable in a tour run on such liberal lines as the Tour Around Georgia. Overland 28 was the victim and in a collision with another competitor, also an Overland, its radiator was so badly injured that the car was put temporarily out of commission. A Dorris car, driven by George Fauss, towed the victim to Summit, where a repair was made.

The middle of the day proved the pleasantest part, for the weather improved materially and what with good roads into Statesboro, and a good lunch there at the Jaeckel House the tourists thawed out and cheered up materially.

The afternoon run was a mere matter of plugging along and all the cars, save the injured Overland, hauled into Dublin, the night stop, in good order. This town of Dublin was one of the cities most active in promoting the tour. The citizens want the Dublin route between Atlanta and Savannah accepted as official and in consequence were intensely interested in the present tour. This interest was shown Friday night by a tremendous ringing of bells and an amazing blowing of horns and playing of bands. At no place on the tour was the welcome any more sincere or enthusiastic than at Dublin. The day's run was 124.8 miles. The lunch stop was 50.7 miles from Savannah.

The last day's run of the Tour Around Georgia, was 152 miles in length and carried the tourists from Dublin to Atlanta over roads that were in the main good, and under skies that were fair enough.

The last section of the run, from Macon to Atlanta, was especially fine. This strip of road is one of the finest 100-mile straightaways in all Dixie and the tour cars fairly burned it up.

When the Round-Staters reached Atlanta they went at once to the Piedmont Driving Club, where they were checked out and where a beefsteak dinner was served. At this meal the tourists were the guests of the Atlanta Constitution, which has done much toward promoting and engineering the trip.

Owing to the intense informality of the run it may be several days before announcements are made as to the penalizations but it is probable that only three of the cars that participated will receive penalties.

The only prize thus far awarded was to the Overland No. 28, which was voted the trophy offered by the Atlanta Ad-Men's Club for the machine that met with the hardest luck while on the road. The Overland was the hard-luck car of the tour.

The tour just completed was probably the most successful state tour ever run in the South. It was the verdict of the few who took part both in this event and in the recent Glidden that the Georgia event was the harder of the two on the contestants. While the running time was slower and the rules less vigorously enforced the roughness of many of the strips of road and the roughness of the weather combined to make the affair decidedly rigorous.

It is worth noting, however, that the roads encountered on this year's tour were better than those traversed by the same tour last year, that there were more bridges and less fords and that the people in the counties where bad roads still exist were thoroughly awake to the need of better roads and were planning to get them.

In the Legal Field—Weed Chain Wins

ACCORDING to information received by Duncan & Duncan, of New York, attorneys for the Weed Chain Tire Grip Co., from Washington, the Supreme Court has denied the petition of the Excelsior Supply Co., of Chicago, for a writ of certiorari to review the decision of the United States Circuit Court which held in favor of the legality of the Parsons patents which are owned by the Weed company. The refusal of the Supreme Court to further consider this case is the final step in a long litigation. At present there are pending in New York and elsewhere over 175 cases brought by the Weed company, in all of which preliminary injunctions have been granted.

The United States Court of Appeals has issued interlocutory decrees against a number of defendants, based upon the Weed patents. Several of these suits are now pending before masters who have been instructed to determine the amount of damages involved.

Rubber Contract in Federal Court

Before the United States Circuit Court of Appeals in New York the final hearing of the suit of Henry A. Gould against the Pennsylvania Rubber Co. was held Monday and the decision is now being considered by the court. The Pennsylvania Rubber Co. sued Gould in the lower court to recover $16,592 for alleged failure to deliver to it 16,592 pounds of Manicoba rubber which was contracted for in June, 1909.

The defendant claimed that he had delivered 9,253 pounds of the contract amount and that the plaintiff company refused delivery tendered upon the remainder. A jury in Judge Hough's court awarded the Pennsylvania Rubber Co. $11,713 as damages and from this judgment Gould appealed. Gould imports rubber and the Pennsylvania company manufactures rubber goods.

The issue between the two is as to the quality of the rubber delivered. On the part of the company it is alleged that the rubber was rejected because it would not vulcanize evenly and the Gould concern declares that there was nothing in the contract to specifically provide for even vulcanization.

How Old Acme Company Almost Won

How the old Acme Motor Car Company almost got another lease on life back in 1906 was told in the New York Supreme Court last week, when the cases of Pirie versus Emery, Somers and Curran were decided in favor of the plaintiff. It appears that the automobile company actually had possession of enough money to tide it over the rough spot it was encountering but that an effort was made to stop payment upon two checks, aggregating $65,000, and while the stop was not permanently effective it resulted in a swarm of creditors swooping down upon the company at an inconvenient moment, causing its bankruptcy.

The story as told in court was one of intense human interest. Mr. Devlin, who was in charge of the Acme company at that time, was being pressed for payment of $55,000 due to a Mr. Horst on the purchase of the company's control. The company was also short of ready cash. Therefore, he arranged with the plaintiff Pirie for a loan of $65,000. The defendants Emery, Somers and Curran gave Pirie their notes and checks for a total of $40,000 and Pirie advanced two checks, one for $55,000, which was paid over to Horst and the other for $10,000 which Devlin deposited to the order of the company.

The next day after this was done, January 24, 1906, Pirie decided not to carry out the transaction and notified the defendants that he was going to try to get out and advised them to do likewise. Payment was stopped on the two Pirie checks and identical notes were written by the defendants disclaiming liability on the notes they had given.

But in the meantime the attorney for Pirie informed him that payment on the checks could not be stopped and after some delay the order of stoppage was released. It was too late for the Acme company, however, for the checks of Devlin that had been returned unpaid by his bank caused the creditors to descend upon the company, eventually throwing it into bankruptcy.

Then the defendants declined to pay their notes to Pirie and suit was brought against them in the Supreme Court. These were heard by Justice Blanchard, who decided that defendants were liable to Pirie for the amount of their notes with interest.

Auto Lighter Co. Asks for Injunction

COLUMBUS, O., Dec. 7—Alleging infringement of patent rights, the Auto Lighter and Equipment Company, of Boston, has asked the United States court to enjoin further sales of a device for automatic gas ignition manufactured by the Inst Lighter Company, of Columbus. F. C. Barger and Byron L. Barger are president and secretary of the local company, which has an office at 55 1-2 East Main street.

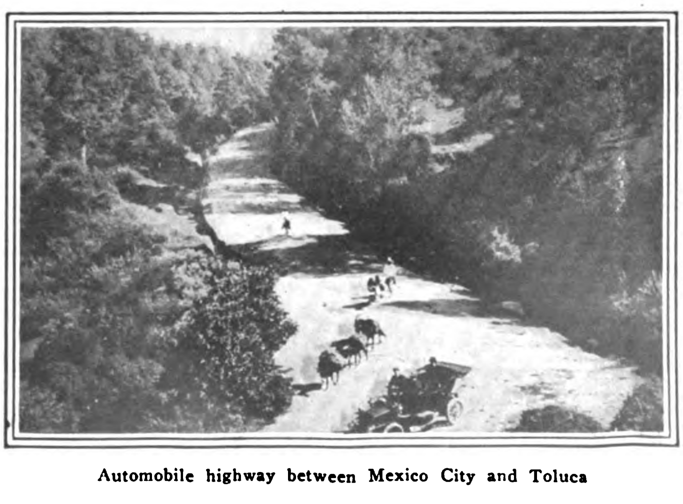
Daimler Levies Upon French Firms' Exhibits

In consequence of certain claims for violation of its patents and difficulties in obtaining judicial satisfaction for these claims in French courts, the Daimler Motoren Company of Stuttgart-Untertuerkheim at the conclusion of the recent automobile show in Berlin had the sheriff levy upon and take possession of the exhibits of the French firms Clement-Bayard, Mors and La Buire, subject to release against bonds.

Madero to Urge Good Roads in Mexico

MEXICO CITY, Dec. 1—Automobilists and others in Mexico are greatly interested in the announcement by President Francisco I. Madero, Jr., that one of his policies will be to promote the construction of good roads throughout the republic. There are already several splendid highways in the federal district.

The favorite highway for automobile pleasure seekers of the capital is that which runs between this city and Toluca. The distance is 45 miles, and the route lies through grand scenery.



Automobile highway between Mexico City and Toluca

Late Racing and General News

INDIANAPOLIS, IND., Dec. 4—The annual motor car hill climb of the Evansville Automobile Club, was held at Evansville Thanksgiving Day, a large crowd of spectators witnessing the contest. The Evansville *Courier* offered a silver trophy to the winner of the free-for-all class. While the best time in this class was made by Charles French, driving a Cole, a protest against French receiving the award has been filed with the judges by Armand Emrich, who drove a Marquette-Buick, on the ground that French is a factory driver and a professional. A summary follows:

Free-for-all: Cole, driven by Charles French, first; Marquette-Buick, driven by Armand Emrich, second; time, 48½ seconds.

Cars with 4½-inch bore: Cole, driven by Charles French, first; Knox, driven by Morton Mannheimer, second; American, driven by Elmer Lehnhard, third; time 48¾ seconds.

Cars with 4¼-inch bore: Chalmers "36," driven by G. C. Keck, first; Maxwell, entered by Echert-Maxwell Co., second; time, 54 seconds.

Cars with 4-inch bore: E-M-F, driven by Fred McNeeley, had no competition; time, 58½ seconds.

Cars of less than 4-inch bore: Ford, entered by Korb and Stewart, first; Cameron, driven by Herbert Laubscher, second; time, 1.01¾.

Cars driven by ladies: Cadillac, driven by Miss Beatrice Curry, first; Cadillac, driven by Miss Eloise Koch, second; time, 58 seconds.

Savannah Not Anxious for 1912 Grand Prize

SAVANNAH, GA., Dec. 3—Whether Savannah will ever have another Grand Prize or Vanderbilt race is doubtful. Neither the officials of the Savannah Automobile Club nor Mayor Tiedeman would talk upon the subject, otherwise than to say that they thought Savannah had seen its last automobile race for years to come. To add to the feeling of doubt as to the future, the night following the Grand Prize race was allowed to pass without any attempt to secure the event next year.

The railroads entering the city gave out an official statement in which it was set forth that they handled 30,000 strangers as against 17,000 last year.

Starter Wagner before his return to New York outlined a new 10-mile course which should be easily capable of a speed of 80 miles an hour.

Instead of making the "S" turn which leads to Whitfield avenue, the Montgomery Cross Roads could be connected with Norwood avenue. With this new road both Whitfield and Ferguson avenue with the turns at Montgomery Cross Roads will be eliminated.

Gold Prize for Tour to Dawson

SEATTLE, Nov. 29—Complete rules governing the awarding of a gold trophy for the first automobile touring continuously between Vancouver, B. C., and Dawson (or any other settlement in the Canadian Yukon or Alaska an equal or greater distance north than Dawson), via a continuation of the Pacific highway route, have been issued by the Pacific Highway Association.

This makes the third trophy to be put up by the association for pioneering runs along projected continuations of its route. The first, for the Seattle-Hazelton trip, was won by P. E. Sands; the second, for a tour from San Diego to the city of Mexico, will probably be contested for next Spring or Summer. All these trophies are similar in appearance, being reproductions in gold of an automobile rear wheel engraved around the side of the tire and with space on the brake drum for the winner's name.

The rules for the Dawson tour, covering 19 clauses, are largely similar to those of the other contests. The thirteenth and fourteenth clauses are of special interest. They provide that the route from Vancouver to Lytton must be nowhere more than 10 miles distant from the Frazer river, and that from the start the run must follow wholly within the confines of British Columbia, Alaska and the Yukon. Pacific highway pennants must be carried and a complete set of photos taken en route. A log also must be kept.

Immense difficulty would attend an attempt for this more than 1,400-mile run at present, but with the recent discovery of enormous coal fields in the Groundhog district, 140 miles north of Hazelton, it seems probable that the British Columbia government will begin a wagon road into that country, along the projected Pacific highway route. This, together with the provincial government's activity in behalf of highways and the recently avowed Federal intention of helping roads in the provinces, encourages the promoters of the Dawson run to believe that it can be undertaken with a considerable chance for success within 1 1-2 years.

San Mateo to Have Good Road System

SAN FRANCISCO, Dec. 4—At a recent meeting of the San Francisco Motor Car Dealers' Association the following resolution was adopted:

"San Mateo county, realizing the importance of good roads, and the lack of the same in that county, is coming to the front in the way of bonding itself for $1,500,000 for the purpose of constructing good roads in that county, commencing at the boundary line of San Francisco county and extending to the extreme south of San Mateo county, with cross roads running from the bay to the ocean side. The county surveyor for some time past has been preparing a survey of these roads, and will soon make his report to the county, when the question will come before the proper officials for the passing of said bond issue. The Coast Side Promotion Association and the San Mateo County Development Association are both doing all in their power to bring about this result and to make a success of the bond issue which will come to vote in a short time.

"There have now been granted in the state of California licenses to the extent of 59,000 automobiles, and automobiles are now being sold in the State of California at about the rate of 60 per day, so that the magnitude of this business can be hardly realized. It is a crying shame that San Francisco, the metropolis of the coast, should have such wretched exits as it has on this side of the bay, and it is unnecessary to tell of the great benefits which would be derived from the bond issue in San Mateo county."

Maxwell, McNay's Mechanic, Dead

SAVANNAH, GA., Dec. 4—H. F. Maxwell who was riding as mechanic for Jay McNay, who met his death while practicing over the Grand Prize course here on November 20, died on Sunday afternoon at the Savannah Hospital, where he was confined since the accident. Maxwell was from Jacksonville, Fla. His body has been sent there.

Detroit Items in News of Week

DETROIT, MICH., Dec. 4—The Studebaker Corporation, maker of E-M-F "30" and Flanders "20" motor cars, has inaugurated a radical change in its selling policy that is fraught with a great deal of significance to the industry as a whole. The corporation has decided to sell motor cars on credit and hereafter will accept notes from farmers and other responsible buyers. In explanation of this innovation, Walter E. Flanders, general manager of the Detroit factories of the factories of the Studebaker Corporation, says.

"I believe the motor car business should be placed on a credit basis, and I believe the action we have taken will lead to the most important advance that has been made in the industry since its inception. It indicates that the motor car has now arrived at the stage where it is no longer a high-priced luxury, but has actually become a necessity in the lives of all business men and other well-to-do people. First the motor car business was called a 'game'; now it has attained the dignity of an industry. The motor car itself was originally a play toy, then an expensive luxury for the rich; now it is a staple, a necessity, and as such it should be sold as all other staple articles."

The Studebaker Corporation's action has been the subject of a good deal of discussion among local makers, but whether the example will be followed by others as a fixed policy remains to be seen. That the time is coming when motor cars will be sold as are other staple commodities, to responsible buyers, by the manufacturers generally, is regarded as certain, but there seems to be a doubt in some quarters as to whether the time is ripe for the inauguration of such a policy.

Important changes in the administrative forces of the Lozier Motor Co. are announced. Owing to the rapid growth of the business, it has been found necessary to further divide the responsibility, and in this connection the position of general manager has been created. Fred C. Chandler, second vice-president of the company in charge of sales, who has been associated with the Loziers for the past 21 years, has been advanced to this position. John G. Perrin, who has been identified with the Loziers in various capacities for the past 17 years, has been appointed vice-president and chief engineer. Charles A. Emise, formerly in charge of the advertising department, succeeds Mr. Chandler as sales manager, and Russell E. Benner becomes production manager.

Rapid progress is being made on the new plants and additions under way in this vicinity. At the Ford plant the finishing touches are being put on the mammoth addition and a part of the extra space is already being utilized. The Hupp Motor Car Co. expects to have its new Windsor branch factory in operation by January 1. It will have a capacity of 2,000 cars per year. The company's new local plant is well under way. The company expects to move into one department this month, and the factory will be completed some time in January, according to present indications. It will have a capacity of 15,000 cars per year. The old plant on Jefferson avenue is turning out cars right along and is not storing any. The Cadillac Motor Car Co. has just let the masonry contract for a new storage building at its plant. The remainder of the work will be done by the company itself.

Knell & Adams, automobile body finishers, have practically closed a deal for the purchase of a two-story factory building at 1039-1043 Jefferson avenue, which will increase the company's facilities 100 per cent. after contemplated alterations are completed. The company is now located at 1020-1030 Beaufait avenue, and this plant will be continued. The newly acquired property was formerly used for an overall factory. It is understood that the purchase price agreed on is in the neighborhood of $50,000.

That the Mexican government is awakening to the commercial and industrial possibilities of the motor car is evident from the fact that it has just commissioned two of its engineers, Ernestra Silva and Eduardo D. Escobar, to study motor car building in this city. The men have been given positions in the plant of the Hudson Motor Car Co. and will learn the business from the ground up, under the direction of Howard E. Coffin. They began their apprenticeship in the "rough test" department.

The Hudson Co. furnished the motor cars for conveying a party of western governors about the city of Detroit on Thanksgiving day.

George D. Wilson, sales manager for the Warren Motor Car Co., has just returned from an Eastern trip in the interests of the company and says that the outlook for future trade in that section is more promising than it has been in any previous year at this season.

J. B. Eccleston, sales manager for the Oakland Motor Car Co., of Pontiac, has left for an extended trip through the West to visit Oakland dealers and get a line on conditions. He will be gone about a month.

Everitt Banqueted by Agents

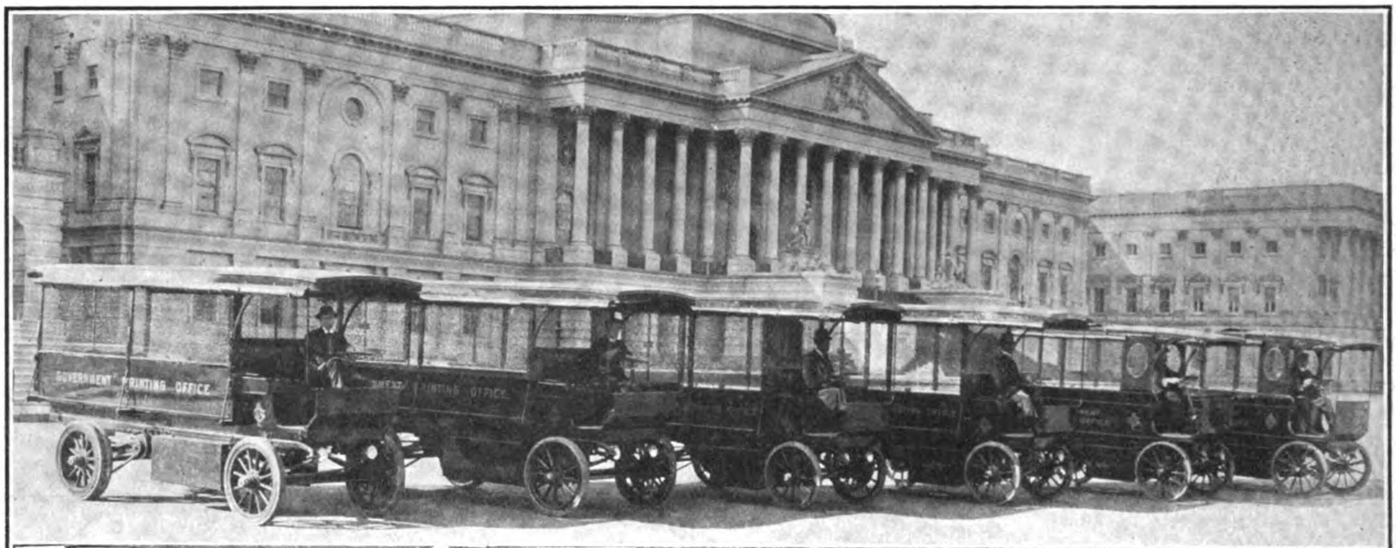
PHILADELPHIA, Dec. 4—B. F. Everitt, president of the Metzger Motor Car Company, manufacturers of the Everitt line of cars, and Wallace C. Hood, sales manager of the factory, were the guests last evening of W. Wayne Davis, who handles the Everitt in this territory, at the newly-remodeled showrooms of the local branch, Nos. 600-602 North Broad street. About fifty all told were present at the housewarming, composed of subagents of the Everitt from Pennsylvania, New Jersey and Maryland, and local newspapermen. Speeches outlining the policy of the company were made by Mr. Everitt, Mr. Hood and Mr. Davis. The headquarters of the W. Wayne Davis Company were beautifully decorated and music further added to the enjoyment of the occasion.

Hoosiers Have Horseless Fire House

INDIANAPOLIS, Dec. 4—After experiments covering more than a year, which have resulted satisfactorily, the Indianapolis board of public safety has announced a policy of replacing the horse-drawn equipment in the fire department with motor-drawn equipment as rapidly as possible. At first such installations are to be largely in the districts having paved streets, although experiments are now about to be made with such equipment in districts where there are some unimproved streets.

Equipment, consisting of a gasoline combination hose and chemical wagon, has been ordered for a new fire engine house being erected in Thirty-eighth street, in a residence district where there are few improved streets. This will be the first engine house in the city having no provision for horses and thus the first step toward motorizing the fire department.

Before February 1, 1912, it is planned to install a motor combination hose and chemical wagon in engine house No. 5 in Fifteenth street and to replace the hose wagon at engine house No. 20 in Beville avenue with motor equipment. It is also planned by that date to install motor equipment in engine house No. 25 in Irvington, in which are now stationed a horse-drawn hose wagon and ladder truck.



NEWS of the WEEK CONDENSED

Installation of Baker electric commercial cars recently delivered to the United States Government

WASHINGTON, D. C.—The Baker Motor Vehicle Company, of Cleveland, O., has recently delivered two delivery wagons, two light trucks and two heavy trucks to the United States Government for the use of the Bureau of Printing and Engraving.

CASPER, WYO.—The Shulte Hardware Company has taken the Cadillac agency.

DENVER, COL.—The Alkire Motor Car Company has taken the agency for the Thomas flyer.

KANSAS CITY, KAN.—The A. J. Davis Motor Car Company has removed to 1710 Grand avenue.

KANSAS CITY, KAN.—The Motor Tire & Supply Company has removed to 1708 Grand avenue.

DENVER, COL.—The Carstarpen Electric Company has taken the agency for the Flanders electric.

WICHITA, KAN.—The Cole Motor Company has moved into new quarters at First and Water streets.

OMAHA, NEB.—The Powell Supply Company has taken the agency for Republic tires for this territory.

OWENSBORO, KY.—Lee Brothers have sold their garage on St. Ann street to R. G. Jesse and J. M. Miller.

NEWARK, N. J.—The Oakland Sales Company has been organized to handle the Oakland car in this vicinity.

OMAHA, NEB.—The Moline Automobile Company has opened a branch in this city with D. M. Deal as manager.

SPOKANE, WASH.—Harry Bell, a well-known automobile dealer of this city, has added the Mitchell to his line.

WILKES-BARRE, PA.—The Deitrick automobile agency of this city has taken the agency for the National 40.

DENVER, COL.—G. A. Maxwell and F. Chamberlin have taken the Western distributing agency for the Haynes car.

DENVER, COL.—The Esterline car is now represented here by the Western Engineering & Specialty Company of 1732 Glenarm street.

CHICAGO, ILL.—E. Ruelbach has joined the sales force of the United Motor Chicago Company. Mr. Ruelbach will sell the Columbia car.

CLEVELAND, O.—The V. R. Hall Automobile Company, state distributor for the Cartercar, has opened its new salesroom on Euclid avenue.

WASHINGTON, D. C.—A new garage has been opened at 96 West Maiden street by Thomas O'Rorke, who will handle the Overland in this territory.

BIRMINGHAM, ALA.—D. J. and W. T. Fox have secured the agency for the Matheson car and have opened a garage at 321 South Twentieth street.

BINGHAMTON, N. Y.—The New York Sales Company will handle the Rambler in Broome, Chenango and Tioga counties during the coming year.

HARLAN, IA.—The Booth Implement Company of this city has let the contract for the erection of an automobile garage to Alexander Smith of this city.

CINCINNATI, O.—The Kruse Motor Company has appointed Scott Socars agent for the Maxwell in Adams county. A sub-agency has also been established at Lexington, Ky.

WILMINGTON, DEL.—The Autocar Company, of Admore, Pa., has opened maintenance headquarters at 714 Orange street. J. P. Harvey is in charge.

OMAHA, NEB.—The Velie Automobile Company is erecting a new garage at Tenth and Howard streets which will be completed early in December.

SYRACUSE, N. Y.—W. King Smith has taken the agency for the Moon car for this vicinity. Mr. Smith also handles the National and Pierce-Arrow.

SCRANTON, PA.—The name of the local agent for the Cole car has been changed from the Penn Auto Company to the Scranton Penn Auto Company.

JOHNSTOWN, N. Y.—H. S. Bowler has become associated with the St. Charles garage and in the future will have charge of the mechanical department.

SAN ANTONIO, TEX.—The United States Tire Company is preparing to open a branch in this city. It will be situated at 433 Main avenue with F. D. Welch as depot manager.

FORT WORTH, TEX.—Joseph Radcliffe & Sons have completed the equipment of their new automobile repair shop at Second and Throckmorton streets and it is now in operation.

SYRACUSE, N. Y.—T. A. Young, of this city, has taken the agency for Onondaga and Cayuga counties for the R. C. H. car, manufactured by the R. C. Hupp Motor Car Company, of Detroit, Mich.

MILWAUKEE, WIS.—The city of Milwaukee oiled exactly 71 miles of streets during 1911, or 50 per cent. more than in 1910. The cost of oiling for 1911 is $.0402 per foot as against $.0550 in the previous year.

YOUNGSTOWN, O.—The Motormart has just completed arrangements whereby it secures the dealership in Franklin cars in this territory for the coming season.

CANTON, O.—The A. H. Wilson Motor Car Company, of this city, located at 516 North Cleveland avenue, has taken the 1912 agency for the Cadillac and the Detroit Electric.

KIEL, WIS.—The Motor Car Company of Kiel, incorporated with a capital of $10,000, will establish a garage and repair shop at once. The concern is negotiating for agency lines.

DENVER, COL.—William Pete has assumed the managership of the Fry & McGill Auto Supply Company of this city, succeeding John Fry, who is now sales manager of the local Everitt branch.

SAN ANTONIO, TEX.—The Taxicab Company has filed an amendment to its charter changing its name to the San Antonio Transfer & Taxicab Company and increasing its capital to $30,000.

KANSAS CITY, KAN.—The Karshner Motor Car Company is now occupying handsome new quarters at Thirteenth street and Central avenue. The company handles the Warren and Speedwell cars.

WINNIPEG, MAN.—The Tudhope-Anderson Company, of this city, Canadian distributor for the Everitt car, has opened branch houses at Brandon, Man.; Swift Current, Sask., and Gorkton, Sask.

KANSAS CITY, KAN.—The Diamond Rubber Company has opened a branch at 1316-18 Grand avenue, in charge of J. F. Lanier, who will also have charge of the branch houses at Omaha and Oklahoma City.

WINNIPEG, MAN.—The Breen Motor Company is occupying its new salesrooms and service station at the corner of Broadway and Sherbrooks street. The company handles the Cole car in this territory.

MILWAUKEE, WIS.—The Smith-Hoppe Auto Company has moved into its new salesroom at 215 Wisconsin street. The company is agent for the R. C. H., Oakland, Oldsmobile and Hupp-Yeats electric.

LANCASTER, PA.—Partnership existing between Herbert R. Bowers and Eugene R. Russell, trading under the firm name of the Conestoga Auto Company, has been dissolved. Mr. Russell retains the business.

RACINE, WIS.—The Racine Automobile & Motor Works, which recently established a new garage and shops on State street, handling the Buick line, are engaged in the production of a new type of motor for pleasure cars.

ATLANTA, GA.—John F. Lakin, special representative of the Studebaker Corporation for the entire Southeast, has just been detailed for this territory. He was formerly with the company at Detroit. His headquarters will be in this city.

MISHAWAKA, IND.—The American Castings Company has taken on more employes in its foundry. The company is making castings for automobile concerns in Peru, Goshen, Rockford, Mishawaka and other cities.

DETROIT, MICH.—H. L. Winter has been appointed sales manager for the Federal Truck Company, of this city. Mr. Winter's experience in the automobile business dates from the time when the industry was in its infancy.

ST. LOUIS, MO.—The Banner Rubber Co. of this city has increased its capital stock from $100,000 to $400,000 for the purpose of equipping a much larger plant for the manufacture of automobile tires and other rubber goods.

VICTORIA, TEX.—The Texas Motor Car & Supply Company has let the contract to the Bailey Mills Company of this place for the erection of a two-story addition to its machine shops here. Harry Dilley is manager of the plant.

ST. LOUIS, MO.—Curtis Jack & Truck Company, recently incorporated at Jefferson City, Mo., capital $75,000, will establish a factory here to manufacture a combination hand-truck and jack for handling automobiles in garages.

NEW YORK CITY.—The Henry Manufacturing Company has leased the garage at 141 West Fifty-fifth street. The company will manufacture an automatic device for starting gasoline engines. The initial capitalization is $100,000.

NEW YORK CITY—The Motz Tire & Rubber Company, of Akron, O., has opened a branch in this city at Fifty-fifth street and Broadway. E. P. White, formerly connected with the Goodyear Tire & Rubber Company, is in charge.

BOSTON, MASS.—A. H. Sowers, formerly with the Welch Detroit branch in this city, has joined the sales force of the Jackson agency. Mr. Sowers handled the Jackson in Boston before as a member of the Sowers-Soden Company.

BALTIMORE, MD.—The Goodyear Tire Company is the latest concern to locate in Baltimore's motor-car row. The company is having a residence on Mount Royal avenue near Maryland avenue converted into modern salesrooms.

BOSTON, MASS.—Clifton C. Edwards has been made manager of the local branch of the Marquette Buick in Boston, succeeding George Lighthall. Mr. Lighthall is to represent the company on the road, opening agencies throughout New England.

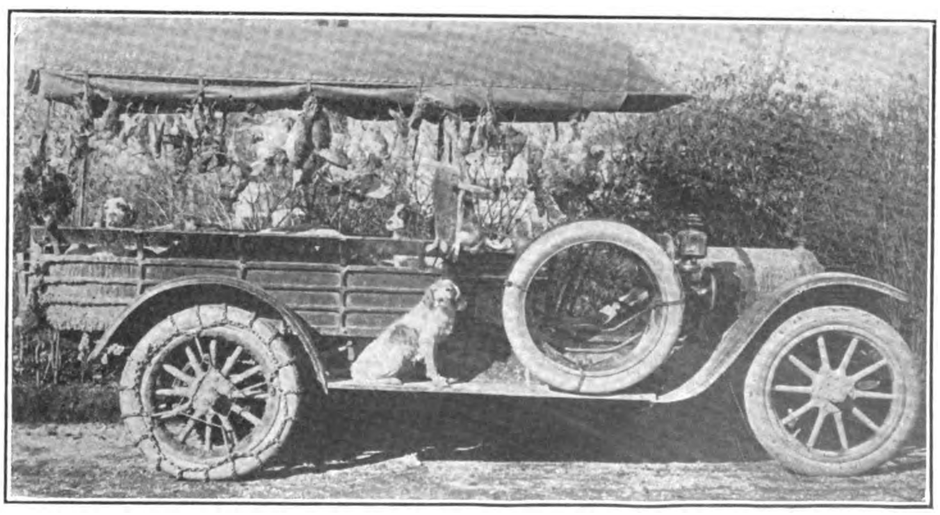
CINCINNATI, O.—The local agency of the Cadillac has opened branch agencies at Ashland, where the Great Eastern Automobile Company will look after the sale of the car, and at Greenville, Ky., where its interests will be cared for by J. E. Upp.

BALTIMORE, MD.—Another car new to the Baltimore field is the De Tamble, which is being handled by Callahan, Atkinson & Company, Charles street, opposite Pleasant street. Callahan, Atkinson & Company are also the representatives for the Locomobile.

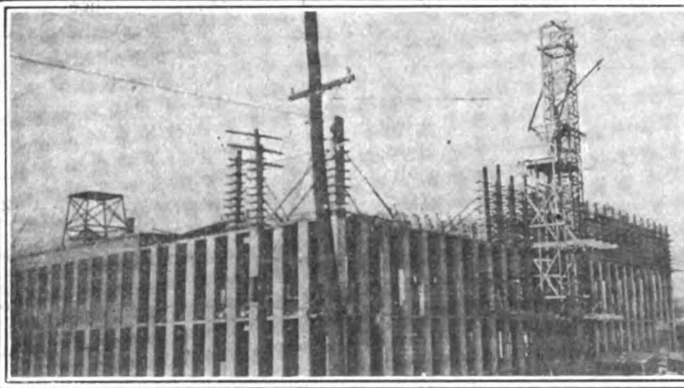
CHICAGO, ILL.—The Velie Motor Vehicle Company has absorbed the Velie Motor Car Company, of this city, and has made it a direct branch. Morton H. Luce, who is in charge of the New England branch, will also act as manager of the Chicago branch.

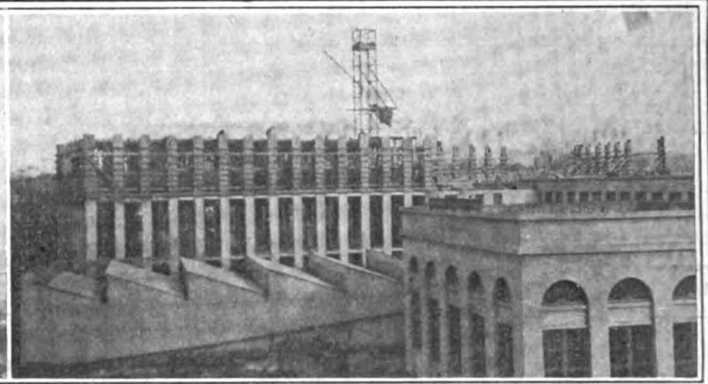
CLEVELAND, O.—A Boston man has written the White Company, of this city, that he never hunted so comfortably as he now does in his White gasoline truck. He had always used a large touring car until this fall but finds the truck much more satisfactory for hunting purposes.

MISHAWAKA, IND.—The Star Garage is in the hands of a new corporation, the capitalization of which is $5,000. The officers are as follows: Guy Stutzman, president and superintendent; Louis Slick, secretary and treasurer; Marion Pancake, general manager; Charles Renner, sales manager.



How a Boston man uses a White truck in his hunting expeditions





Two views of the new factory now in course of erection for the Rushmore Dynamo Works at Plainfield, N. J.

PORT HURON, MICH.—The Havers Motor Car Company, of which Fred Havers, of Detroit, is president, has increased its capital from $60,000 to $200,000. It is now planned to manufacture 1000 cars next year, the first output having been estimated at 500.

PITTSBURGH, PA.—The Abbott-Detroit Motor Sales Agency has been organized to handle the Abbott-Detroit in this territory. J. A. Stumpenhorst, formerly with the Studebaker Company and later with the E. J. Thompson Company, is president.

COLUMBUS, O.—The Hudson Sales Company, of North Fourth street, has appointed the following sub-agents: E. C. Fogle Automobile Company, Cambridge, Elmore; D. S. Spangler, Thornville, Elmore; R. E. Wildermuth Automobile Company, Pleasantville, Krit.

PHILADELPHIA—The Crescent Garage has taken the agency for the Halladay car, manufactured by the Streator Motor Car Company, of Streator, Ill. The garage will act as distributor for eastern Pennsylvania, and, with T. Sidney Weber, for the state of Louisiana.

BALTIMORE, MD.—The Stoddard-Dayton Auto Company, of Baltimore, has taken the local agency for the Sampson truck. The company will represent the truck not only in Baltimore but throughout Maryland, Virginia and West Virginia, the territory covered by the local company.

DETROIT, MICH.—F. R. Bump has been appointed assistant general manager in charge of the sales, advertising and service departments of the Hupp Corporation. R. T. Wingo has taken the position of assistant general manager in charge of production and will also act as master mechanic and consulting engineer.

PROVIDENCE, R. I.—Robert F. Russell has been appointed assistant engineer of the automobile department of the American Locomotive Company. He will be associated with Montague H. Roberts, chief engineer, in matters pertaining to Alco trucks and cars.

DENVER, COL.—The Mathewson Auto Company has appointed the following subagents for the Reo in Colorado: McCune Bros., Las Animas; J. C. Cartwright, Rocky Ford; Royal Garage, Pueblo; Paul's Garage, Colorado Springs; J. B. Smith, Sterling, and O. P. Sells, Alamosa.

RACINE, WIS.—The Mitchell-Lewis Motor Company has borrowed $2,500,000 from banks in Chicago and New York. The purpose of the company is to refund all its banking obligations and to use the remaining capital in opening new departments for the building of tops, bodies and commercial vehicles.

LOUISVILLE, KY.—One of the newcomers in the truck manufacturing field of the Middle West is the Transit Motor Car Company of this city, which is engaged in the building of 2, 3 and 4-ton trucks. The Laib Company has bought one of the 3-ton models, which is arranged for carrying long lengths of pipe.

NEW YORK CITY—H. Boller will give special automobile instruction in German at the automobile school of the West Side Y. M. C. A., Fifty-seventh street and Eighth avenue. Many of the students at the school are German and it was for their benefit that the new course in that language was added to the curriculum.

PUEBLO, COL.—The Byron Motor Company, of Denver, has taken over the plant of the old Pueblo Steel Wheel & Wagon Company and is installing machinery for the manufacture of the Byron truck. The plant will be in operation by January 1, 1912, and will employ 100 men. Its capacity will be 600 trucks a year.

NEW CASTLE, PA.—The annual meeting of the Penn Motor Car Company, Pittsburgh, was held here recently. The following officers and directors were reelected: President, A. G. Breitweiser; vice president and chief engineer, J. S. Herbert; treasurer, J. J. Keeling; secretary and sales manager, C. E. Gregg.

FOND DU LAC, WIS.—The Fountain City Garage, erected by M. B. Helmer at a cost of $25,000, has been opened for business. It is located at 19-21-23 Fourth street, is 40 feet wide and 115 feet long, two stories and basement, of concrete and brick construction. It is equipped with electric elevators. A complete paint and finishing shop is a feature of the repair department.

LOS ANGELES, CAL.—"Doc" Green, formerly sales manager of the Cadillac agency in this city, who left that concern recently, has taken a position with the Grundy Motor Sales Company. He will be sales manager for the Cole and Paige-Detroit lines, for which the Grundy Motor Sales Company is the southern California agent.

PROVIDENCE, R. I.—George L. Sullivan, recently automobile editor of the *New York Tribune* and identified with the automobile industry for 5 years, has joined the sales department of the American Locomotive Co. of this city. H. C. Whitney, formerly of the Royal Tourist and Gramm forces, has also become connected with the Alco interests as traveling sales representative.

MILWAUKEE, WIS.—The Chas. Abresch Company, Fourth and Poplar streets, has just perfected a new type of sand sprinkler for municipal purposes, which is being tested by the city. The machine sprinkles 50,000 square yards of pavement in an hour, accomplishing the work of fifteen to twenty men with shovels in the same time. But one person is required to operate the sprinkler.

PHILADELPHIA—John North Willys, president of the Willys-Overland Motor Company, of Toledo, was the guest of honor at the informal banquet held recently at the Bellevue-Stratford by the Overland-Marion Motor Company of this city. More than fifty managers and agents of the Overland Company from Pennsylvania, New Jersey, Delaware and Maryland were present.

TORREON, MEXICO.—The guayule rubber industry in Torreon, Gomez Palacio and other towns of this region is seriously affected by the general labor troubles. More than 10,000 workmen in Torreon, Gomez Palacio and Lerdo went on a strike the early part of November and the trouble is still unsettled. The Intercontinental Rubber Company's production will be much reduced on account of the labor difficulties and the general unsettled conditions.

PASADENA, CAL.—The Acme Garage, 78 Green street, opened recently with Amber McKibbin as manager.

KALKASKA, MICH.—J. L. Boyd has taken the local agency for the Ford and will open a garage and repair shop about January 1.

NEW YORK CITY—The Simplex Automobile Co. has moved into its new salesroom at Columbus Circle.

NEW YORK CITY—G. L. Egan has resigned the position of advertising manager of the Motor Car Equipment Co. and has accepted a position with the Catalog Publishing Co.

TACOMA, WASH.—C. G. Arnold is now associated with the Pacific Car Company of this city in the capacity of sales manager. Mr. Arnold was recently in charge of the Olympic Motor Car Company of Seattle.

HARTFORD, CONN.—During the last year the State of Connecticut has received $230,120 from car owners and operators. Most of this sum came as registration fees. The gain over the previous 12 months is $65,000.

OMAHA, NEB.—The Omaha Fire and Police Board has found the combination chemical and hose automobile truck so valuable that it was decided to buy a second one. After receiving bids a Knox car was ordered.

PHILADELPHIA—Benjamin H. Kirkbride, formerly manager of the Reo agency in this city, has taken the eastern distributing agency of the Cutting car. His territory includes Pennsylvania, New Jersey and Delaware.

LOUISVILLE, KY.—The Board of Public Safety of this city has recommended the equipment of an automobile repair shop to take care of the municipal motor cars which have been put in service within the past few years.

SAN FRANCISCO, CAL.—F. L. Chavanne, formerly connected with the local branch of the F. B. Stearns Company of Cleveland, is now associated with the sales force of the Haynes Auto Sales Company of this city, distributor of Haynes and Krit cars.

KANSAS CITY, MO.—Alfred Reeves, sales manager of the United States Motor Company, has succeeded W. S. Hathaway as district manager of the West. Mr. Reeves will continue as sales manager but will have this territory under his personal supervision.

SAN FRANCISCO, CAL.—W. T. Matzer, of Columbus, Neb., accompanied by his wife, daughter and brother, arrived in this city recently in his Buick touring car. The party left Columbus about the middle of September and are on their way to Santa Anna, this state.

APPLETON, WIS.—The Eagle Manufacturing Company has perfected a traction plow which covers 30 acres a day, eight furrows at a time. The company has disposed of part of its other business lines in order to concentrate its entire effort on the engine and tractor business. A large addition to the plant is contemplated.

PHILADELPHIA—The Lee Tire & Rubber Co., of Conshohocken, will open a branch in this city at 225 North Broad street on Monday, December 11.

NEW HAVEN, CONN.—W. B. Young, recently a member of the sales force of the New York branch of the Ford Motor Co., has accepted the position of manager of the Ford agency in this city.

DETROIT, MICH.—The sales office of the Heinze Electric Co., formerly in Lowell, Mass., has been moved to 870 Woodward avenue in this city in order to bring it into closer touch with the center of demand.

CHICAGO, ILL.—G. Vernon Beck, for several years connected with the Chicago branch of the Studebaker Corporation, in capacity of traveling salesman, has resigned his position to join the sales organization of the Hupp Corporation. Mr. Beck will travel in Illinois and adjacent territory, working with the Chicago branch, of which Mr. H. E. Westerdale is manager.

Automobile Incorporations

AUTOMOBILES AND PARTS

BUFFALO, N. Y.—Buffalo Motor Vehicle Co.; capital, $100,000; to manufacture, sell and repair automobiles. Incorporators: W. R. Hunteley, J. H. Vailm, C. R. Hunteley.

BUFFALO, N. Y.—Pierce-Arrow Sales Co.; capital, $75,000; to sell automobiles. Incorporators: W. J. Minehan, T. D. Powell, H. W. Huntington.

CAMDEN, N. J.—Generating Light & Motor Co.; capital, $125,000; to make engines. Incorporators: J. J. Bradym, G. D. Connelly.

CAMDEN, N. J.—Little Giant Motor Co.; capital, $125,000; to make and sell motor vehicles. Incorporator: William C. Davis.

CHICAGO, ILL.—Motor Bus Co.; capital, $60,000. Incorporators: Clarence E. Morris, James E. Hauronic, Frank P. Page.

COLUMBUS, OHIO.—Dunlap Mfg. Co.; capital, $50,000; to make automobile parts and pneumatic tools. Incorporators: S. M. Dunlap, A. I. Schetenstein, T. C. Dunlap, L. F. Slater, B. G. Watson.

DETROIT, MICH.—Metzger Motor Car Co.; capital, $1,000,000; to manufacture automobiles.

EAGLE GROVE, IA.—Middleton Auto Co.; to sell automobiles. Incorporators: Lyman B. Middleton, Claude E. Middleton.

JANESVILLE, WIS.—Janesville Motor Co.; capital, $20,000; to make and sell automobiles. Incorporators: G. M. Decker, L. J. Davis, A. Schaller.

MOUNT VERNON, N. Y.—Meteor Automobile Co.; capital, $50,000; to manufacture engines and automobiles. Incorporators: F. A. Kately, A. F. Gescheidt, L. Emmeluth.

SAN FRANCISCO, CAL.—Atlas Auto Machine Co.; capital, $10,000; to make automobile parts. Incorporators: I. B. Dalsiel, H. D. Pressy, N. F. Pressy.

ST. JOSEPH, MO.—Joseph Grassfield Automobile Co.; capital, $2,000; to sell motor vehicles. Incorporators: E. A. Grassfield, Geo. Vetuske, F. E. Frank, N. C. Salisbury, W. T. Rainey.

WILMINGTON, DEL.—New York Motor Works, Inc.; capital, $70,000; to manufacture engines.

AUTOMOBILE GARAGES AND ACCESSORIES

CHICAGO, ILL.—Acme Automatic Tire Pump Co.; capital, $50,000; to manufacture and sell automatic pumps. Incorporators: Francis J. Carroll, Emil R. Rosenthal, Francis J. Houlihan.

CHICAGO, ILL.—Fort Dearborn Auto Repair Co.; capital, $1,200; to sell supplies and conduct a repair shop. Incorporators: Albert Campbell, Henry L. Blum, Donald S. McKinley.

CLEVELAND, OHIO.—Metal Body, Tank & Fender Co.; capital, $10,000; to make bodies, tanks, fenders and other accessories and parts. Incorporators: Charles C. Meyer, Arthur J. Peet, C. J. Robinson, B. A. Perkins, E. J. Hartman.

INDIANAPOLIS, IND.—General Specialty Co.; capital, $40,000; to make tires. Incorporators: C. F. Gregg, R. E. Gregg, W. W. Gregg, J. E. Coulter.

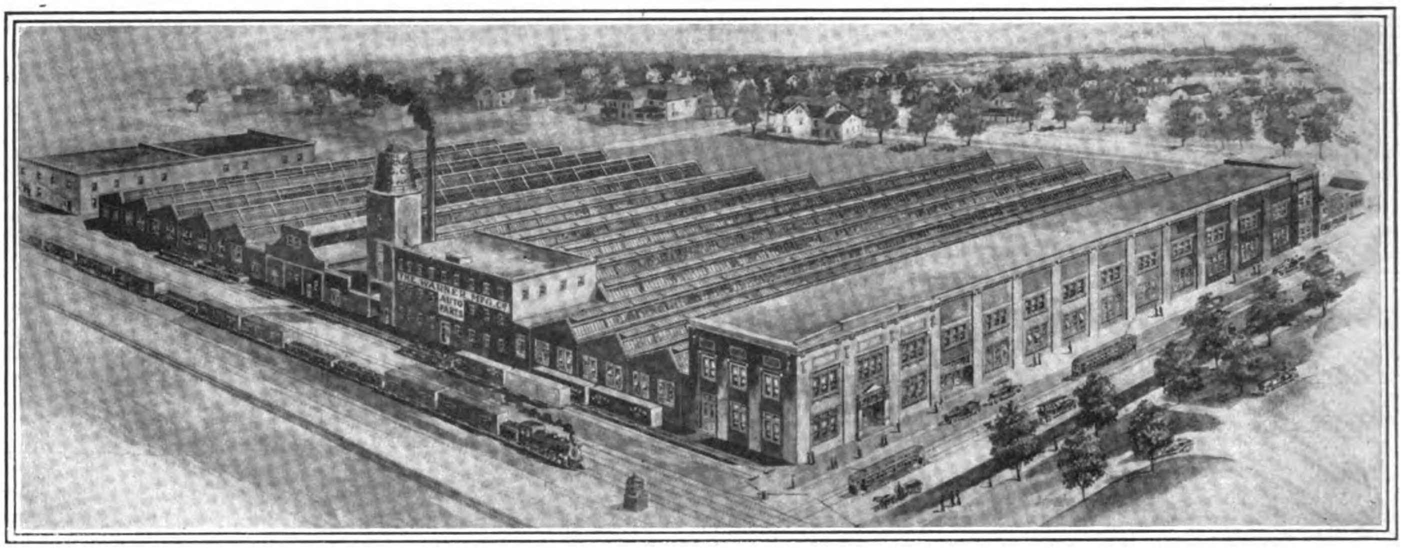
NEW HAVEN, CONN.—Knight Garage Inc.; capital, $15,000; to conduct a general garage business. Incorporators: Harry T. Hotchkiss, George E. Tester, Pierrepont B. Foster.

NEW YORK CITY.—Cosmopolitan Motor Co.; capital, $10,000; to conduct a garage. Incorporators: John J. Kirby, Albert G. Armento.

PHOENIX, ARIZ.—Milwaukee Auto Specialty Co.; capital, $75,000; to manufacture automobile accessories. Incorporators: William J. Schubert and others.

New branch house of the Lozier Motor Company in Cleveland, Ohio

OF INTEREST to the INDUSTRY



Bird's-eye view of the immense plant of the Warner Manufacturing Company, at Toledo, Ohio

TOLEDO, O.—The Warner Manufacturing Co. has completed its new plant which has the capacity for an annual output of 40,000 sliding-gear transmissions and 40,000 steering gears.

GALT, ONT.—Canadian Motors, Ltd., is erecting a factory in this city, to cost $4,000.

TORONTO, ONT.—The Russell Motor Car Co. is building a factory in this city, to cost $30,000.

LOUISVILLE, KY.—The Longest Bros. Co., of this city, has completed the equipment of its shops for the manufacture of motor trucks.

NEW BRITAIN, CONN.—The Corbin Screw Co. is manufacturing a newly patented speedometer for automobiles along with its other products.

DETROIT, MICH.—Kahn & Wilbay, architects, are preparing plans for a one-story addition to the plant of the Chalmers Motor Co. The structure is to be 177 by 70 feet and will cost $25,000.

BROCKWAYVILLE, PA.—The Universal Electric Manufacturing Co., of this city, will manufacture among other electrical appliances the Universal Electric Motor, of which Dr. E. B. Cotten is the inventor.

DETROIT, MICH.—The Cadillac Motor Car Co. has awarded contract through R. D. Raseman, architect, for the construction of a large warehouse and a three-story brick power-house adjoining its present plant.

NEW CASTLE, IND.—The Whiteside Motor Truck Co., formerly of Franklin, Ind., has been reorganized and recapitalized and is now located in this city, where it purchased the plant of the Safety Shredder Co. The new plant will enable the company to turn out 1,000 cars per year.

APPLETON, WIS.—The Valley Iron Works has made a large installation of the oxhydric cutting and welding apparatus manufactured by the American Oxhydric Co., of Milwaukee, and will do automobile and truck repair work in this territory.

OSHKOSH, WIS.—The Termaat & Monahan Co., manufacturing gas and gasoline engines and motors, has purchased the Oshkosh Boat Works site and is erecting a new foundry, to be L-shaped, each wing 50 x 125 feet in size. The present foundry will be added to the machine shops.

INDIANAPOLIS, IND.—The Premier Motor Manufacturing Co., of this city, has begun the manufacture of gasoline motor trucks. The recent enlargements to the plant of the company enable it to take care of a substantial truck business in connection with the manufacture of pleasure cars.

DERBY, CONN.—The United States Rapid Fire Gun & Powder Co. is changing part of its shell department's quarters into a factory for the manufacture of the Westinghouse air spring for automobiles. George Westinghouse is the inventor. The device consists of a piston which works against a cushion of air in a vertical cylinder.

ALEXANDRIA, VA.—V. M. Palmer, formerly superintendent and chief engineer of the Selden Motor Vehicle Company, of Rochester, N. Y., and recently chief engineer and manager of the automobile department of the Sheldon Axle Company, Wilkes-Barre, Pa., has taken the position of factory manager and chief engineer for the B. F. Board Motor Truck Company, of this city.

RACINE, WIS.—Three new departments will be established at once by the Mitchell-Lewis Motor Company, of Racine. One will be for the production of commercial vehicles, the second for the manufacture of bodies and the third for the manufacture of tops. Heretofore its bodies have been built in Milwaukee and Racine by outside interests. The line of commercial cars will include a light delivery car and a general utility farm truck. The total production of all cars for 1912 will be 6,000, the largest in the history of the concern.

DETROIT, MICH.—Although November is usually the dullest month in the year for the industry, the Chalmers Co. has been putting on additional men during the past two weeks and is spending considerable money in the way of betterments. It has just completed a large extension to the motor assembly department and is now installing increased facilities for the testing of motors. The pressing need for additional manufacturing space has made it necessary to move all the offices to a lower floor, crowding them in together. In addition to these changes the company is preparing to erect a new warehouse.

MISHAWAKA, IND.—The Simplex Motor Car Co. has decided to manufacture a moderate priced car and the engineering force is now at work on plans which, when completed, will be turned over to the mechanical department. The new car is to be known as the 40 Baby Amplex and will be equipped with a five-passenger body. The engine to be installed in the new car will be of the four-cylinder, two-cycle valveless type. The capacity of the plant will be increased from the present output of 300 cars to 1,300 cars per annum. Of the 1,300 cars turned out 1,000 will be of the Baby Amplex model.

PATENTS GONE TO ISSUE

CLUTCH—In which cross heads held under tension by springs keep the clutch members in engagement.

3. In this mechanism (Fig. 4) an annular member is keyed to a shaft on which also a revoluble element is loosely journaled and provided with a casing surrounding the annular member. The casing has a number of outwardly radial-projecting boxings, in which spring-tensioned heads are slideably located. Clutch members having fiber clutch shoes are provided with link connections with the cross heads to engage the annular member, when the revoluble element is revolved. Means are provided between portions of the cross heads and the links, which hold the clutch members steadily in engagement with the annular member.

No. 1,009,219—to James C. Boyle, Calgary, Alberta, Canada. Granted November 21, 1911; filed May 17, 1911.

AUTOMOBILE HEATER—Device for heating the interior of closed types of car.

3. The patent relates to the combination of a frame, to the bottom and top of which plates are attached, with heat insulating material on the lower plate and on the frame, frame and plates being so arranged as to form a chamber between upper plate and insulating material. Strips extend from one side of the frame to the other and rest of the sides of the frame and on the heat-insulating material. Supports are provided in the chamber between upper plate and strips and means to hold plates and strips to the supports and to force the strips down onto the insulating material so as to maintain the latter in place.

No. 1,009,052—to Otto Cullman, Chicago, Ill. Granted November 21, 1911; filed December 14, 1910.

VALVE—Double cylindrical type of sleeve valve is reciprocated in the cylinder.

5. In this engine (Fig. 1) a stationary sleeve is fitted in the valve casing which has a delivery passage to the cylinder. The sleeve has delivery and exhaust ports aligned with the delivery passage. A hollow cylindrical valve is mounted to reciprocate in the sleeve, having ports which lead from the interior to the outer surface of the sleeve. These ports are adapted to register with the delivery ports in the sleeve when the exhaust ports are closed by the valve. A ring fits closely around the valve and is carried by it through a portion of its stroke, and means are provided to limit the movement of the ring to a fixed space, so that the exhaust gases are prevented from passing into the body of the valve while the ports therein are passing into the body of the valve while the ports of same are passing the delivery ports in the sleeve on the stroke of the valve conforming to compression and power stroke of engine.

No. 1,009,599—to Charles N. Teetor, Hagerstown, Md. Granted November 21, 1911; filed August 17, 1911.

HEADLIGHT ADJUSTER—Arm and leverage connection for regulating the position of a headlight on an automobile.

1. The patent refers to a lamp (Fig. 2) mounted with provision for horizontal oscillative movement, an arm being connected with the laterally moveable steering (front) wheels so as to have a similar angular movement as these wheels, and an intermediate connecting rod having universal pivotal connection with the lamp at a point in line with the axis of oscillative movement. Thereby the rod is rotated about its own axis by the angular movements of the arm aforementioned, transmitting rotation to the lamp in the same direction.

No. 1,009,385—to Frank R. Cunningham, Medford, Mass., assignor to Kendrick & Davis Co., Lebanon, N. H. Granted November 21, 1911; filed December 7, 1909.

GOVERNING DRIVING MECHANISM—Device for regulating the activity of engines.

2. This patent (Fig. 3) relates to the combination with a driving and a driven element, of a flexible power-transmitting coupling between these elements responsive to variations in torque. The coupling comprises a link and a weighted lever, power regulating means being connected to the lever as well as means whereby the lever varies in position according to the difference between the driving force and load.

No. 1,009,706—to Geo. A. Weber, Trenton, N. J., assignor to Carl J. Adam, Trenton, N. J. Granted November 21, 1911; filed November 25, 1910.

TAIL-LIGHT AND NUMBER PLATE—Apparatus for displaying number and light.

This patent refers to a device comprising a case with an opening on one of its sides, a bull's eye being provided on one side of the opening. Lighting means are contained in the case, as is a number display plate and elastic means for holding it against the inner wall of the case which has the opening in it. The elastic means consist of a flat spring having a number of bearing faces engaging the inner side of the number plate next its upper edge, and a similar spring which engages the inner side of the number plate against the lower edge.

No. 1,009,470—to Davis S. Cake, Los Angeles, Cal. Granted November 21, 1911; filed March 16, 1910.

RADIATOR—Being of vertical tube type.

4. This radiator has top and bottom members and side walls having corrugations connected to these members; in the corrugations are located reinforcing members of a U-shaped section, the inner sides of the U-shaped sections being connected by a strut.

No. 1,007,643—To Fred Clare, Preston, Ontario, Canada. Granted October 31, 1911; filed September 14, 1910.

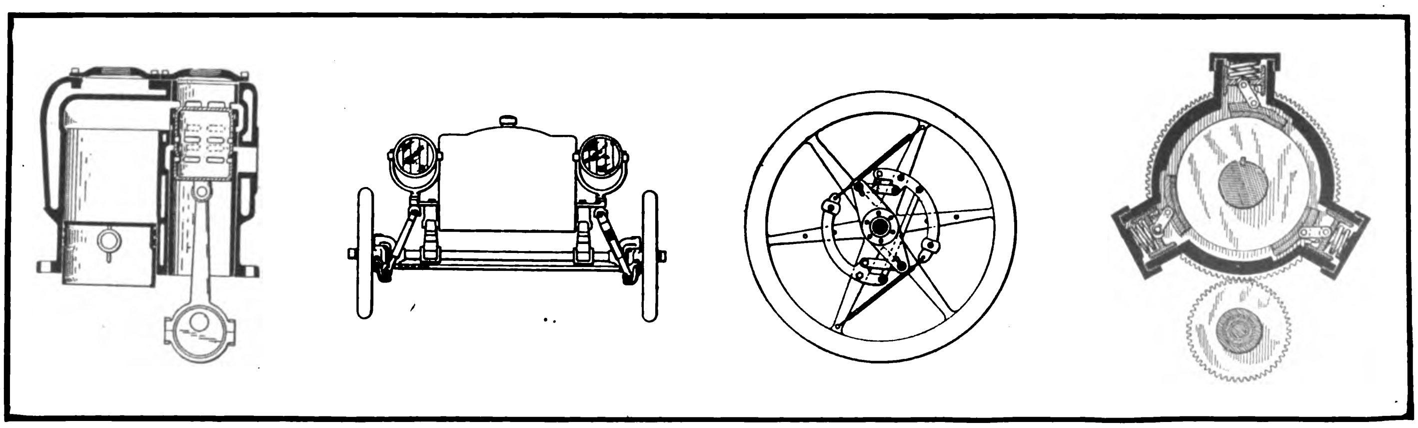


Fig. 1—Teetor sleeve valve. Fig. 2—Cunningham lamp adjuster. Fig. 3— Weber mechanism for drive control. Fig. 4—Boyle clutch

Newest Ideas Among the Accessories

Cinch Repair Kit

THE Cinch tire repair equipment which is illustrated in Figs. 1 to 3 on this page is manufactured by the Cinch Repair Kit Company, of Lockport, N. Y., to enable the motorist to make quick and lasting repairs on inner tubes which have been made useless by blowouts. The exterior view of the kit is seen in Fig. 1. The dimensions of the outfit are 7 by 4½ by 1 inches, and the case in which the several tools composing the equipment are kept is of black leather.

The contents of the kit are seen in Fig. 2, showing the case opened and outspread, and thus giving an idea of the neat and compact manner in which the various tools are arranged. Each tool is held in place by a leather strip securely fastened to the case.

Fig. 3 shows the various tools and the plugs which serve for making the repair. The nickel tube contains a dozen plugs, as shown in the figure. These plugs are made of a soft metal skeleton of the form here seen, and the skeleton is covered with solid rubber, resulting in exactly the shape of the plug at the right. Each plug has a flat and a rounded side.

The pliers are so constructed that by their use the plugs may be compressed, resulting in a solid patch as the left one. By the process of compressing the plug its metal stem is crushed and a tight joint is made between the inner surfaces of the two circular sections.

If the Cinch outfit is to be used for repairing a hole in an inner tube it is not necessary to jack up the car and remove the tire from the wheel. All one has to do is pull the damaged portion of the tube out of the casing and then proceed as follows:

The irregular hole is put in shape for the application of the plug. This is done by pushing the point of the cutting tool through the hole in the tube, until a clean round opening is formed therein. The hole made by the tool is much smaller than the diameter of the plug, and a little wider than the stem holding the two round plug sections together. Therefore the wire spreader is used for widening the hole in the tube. The wire is compressed until its two ends come together, after which the instrument is inserted into the enlarged puncture and permitted to widen it.

Then, while the wire holds the hole in a state of tension, the plug is inserted in it with the rounded side outward. Hereafter the wire spreader is withdrawn and the rubber allowed to contract around the stem of the plug. This having been done, the tube is folded so that it is possible to compress the plug by means of the pliers. Then the same operation is done with the pliers reversed, so as to insure equal pressure being dealt to all portions of the plug. When the repair is finished the tube may again be placed back in the tire.

The metal skeleton in the plug has no sharp edges. All the edges are copiously covered with solid rubber, which insures the inner tube against cutting by the metal core. When it is compressed the tensile strength of the rubber plug is many times in excess of the force required to keep the puncture in the tube closed. This is the reason for the Cinch plug being able to keep a tube in a satisfactory state for months after it has been repaired. The application of sheer force in installing the plug has an effect much different from repairs relying upon mere adhesion.

Not only does the plug work well, but the operation of putting it in place is very simple and takes a very short time. If the location of the puncture is known, all one has to do is to pull the damaged portion of the tube out of the casing, apply the plug, return the tube in its correct place and inflate the tire. Excepting the last-named operation, the whole work may be done in about 1 minute, and it is easy enough to be performed by a boy of 8 or 10 years.

The advantages of this kit are manifold. Not only is it handy enough to be carried in the motorist's pocket, without a chance of losing any one of the pieces making up the equipment, but the fact that the use of this kit enables one to make a repair on the road without the application of heat make it a useful accessory. Everybody is not deft nor careful enough to execute a good quick vulcanizing job, but the simplicity of the Cinch outfit makes it a foolproof equipment indeed.

Start-Light Illumination

In the description of the above-mentioned lighting system on page 838 of THE AUTOMOBILE of November 9 the idea was created that in this illuminating system two motions were required for putting the system into action, namely, that it was necessary to throw on the gas and then the igniter for the lamps. This is not so, but a pressure on a single button admits both acetylene and spark to the lights of the car.

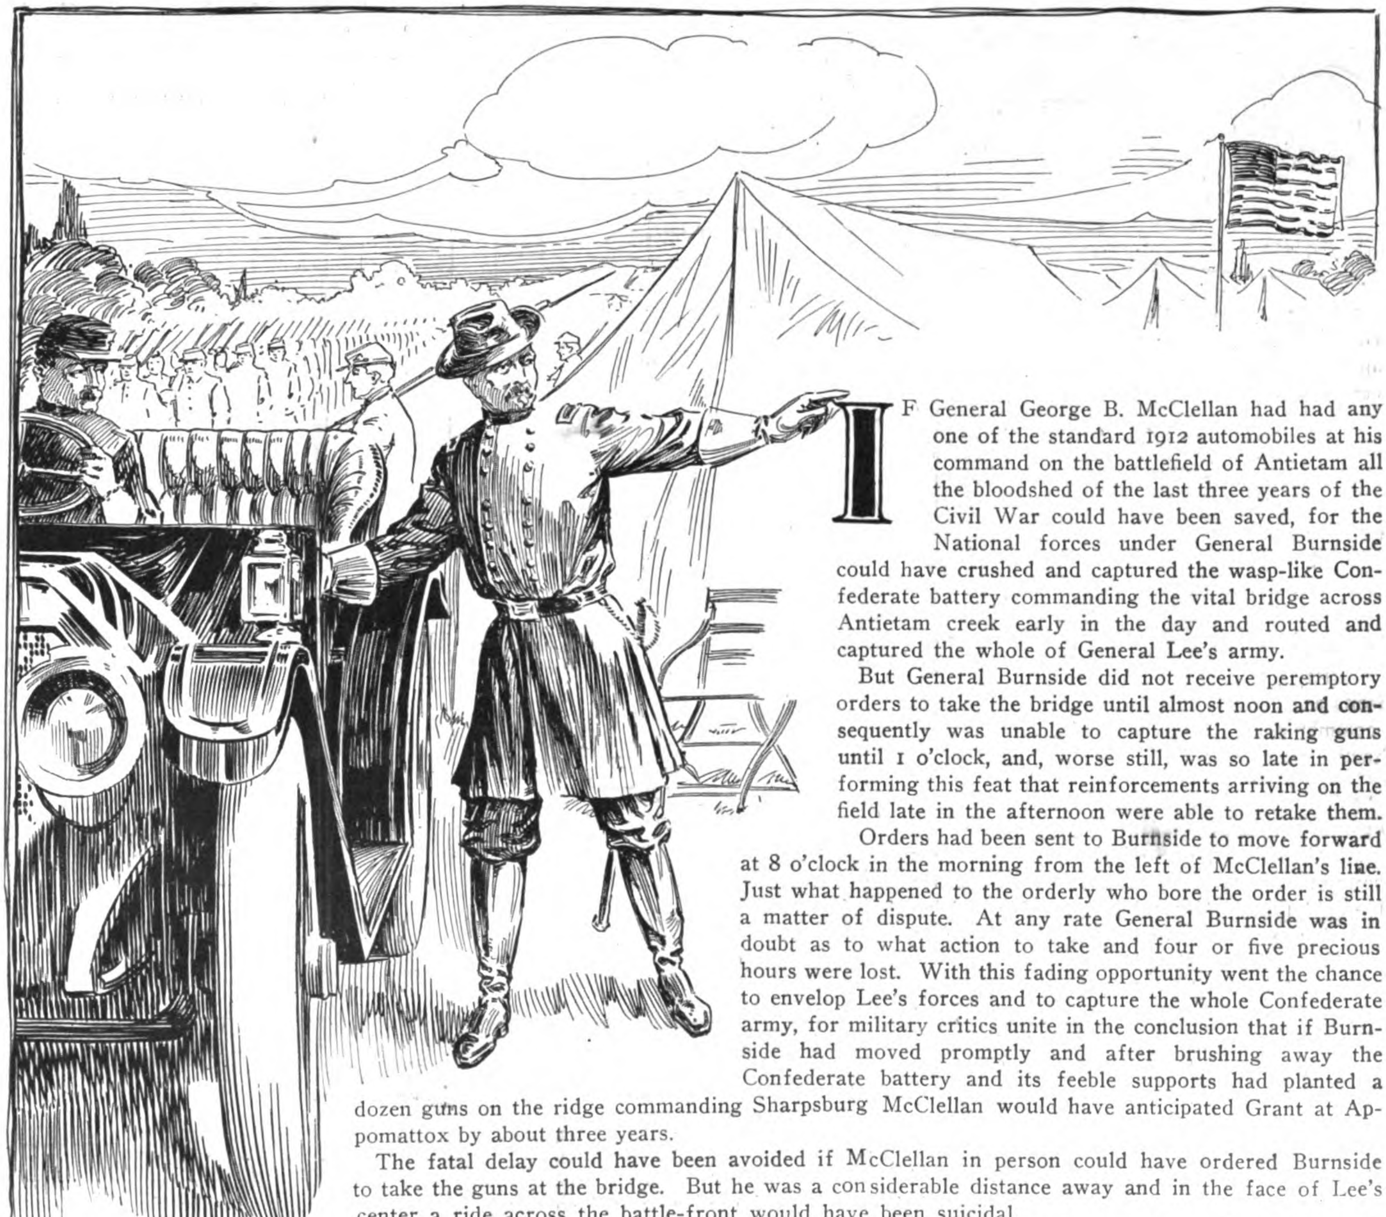
VOL. XXV NEW YORK—THURSDAY, DECEMBER 14, 1911—CHICAGO No. 24

THE AUTOMOBILE

Automobile Might Have Altered Map



IF General George B. McClellan had had any one of the standard 1912 automobiles at his command on the battlefield of Antietam all the bloodshed of the last three years of the Civil War could have been saved, for the National forces under General Burnside could have crushed and captured the wasp-like Confederate battery commanding the vital bridge across Antietam creek early in the day and routed and captured the whole of General Lee's army.

But General Burnside did not receive peremptory orders to take the bridge until almost noon and consequently was unable to capture the raking guns until 1 o'clock, and, worse still, was so late in performing this feat that reinforcements arriving on the field late in the afternoon were able to retake them.

Orders had been sent to Burnside to move forward at 8 o'clock in the morning from the left of McClellan's line. Just what happened to the orderly who bore the order is still a matter of dispute. At any rate General Burnside was in doubt as to what action to take and four or five precious hours were lost. With this fading opportunity went the chance to envelop Lee's forces and to capture the whole Confederate army, for military critics unite in the conclusion that if Burnside had moved promptly and after brushing away the Confederate battery and its feeble supports had planted a dozen guns on the ridge commanding Sharpsburg McClellan would have anticipated Grant at Appomattox by about three years.

The fatal delay could have been avoided if McClellan in person could have ordered Burnside to take the guns at the bridge. But he was a considerable distance away and in the face of Lee's center a ride across the battle-front would have been suicidal.

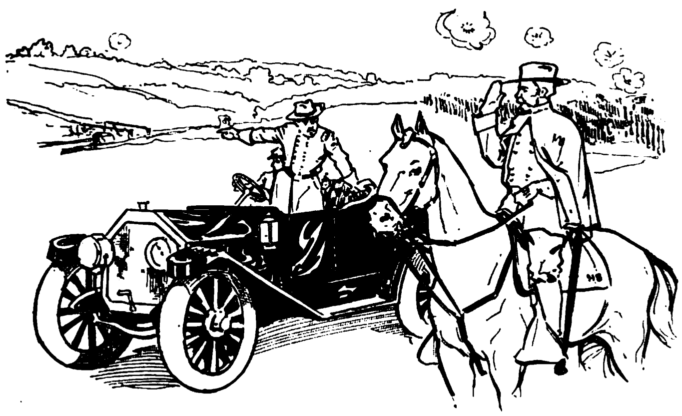
During the recent Glidden Tour the caravan was routed through the battlefield of Antietam and the possibilities of the automobile to a general in McClellan's predicament were made very apparent.

The commanding general was stationed behind Porter's troops in the center, fully three miles from Burnside. The whole space between his headquarters and Burnside was swept by Confederate cannon. But running southeast from his headquarters and away from the battle front lay the Shepherdstown pike, a fair stone road even in those days. This road circles back from Antietam creek and forms a junction with the pike road crossing the very bridge in Burnside's front.

With a powerful automobile General McClellan could have started from the center as soon as it was discovered that Burnside had not swept over the bridge at 8 o'clock and by traveling not more than 10 miles, a matter of probably 15 minutes' driving at most, could have appeared in person to direct the charge. He could have changed commanders on the field if he had so desired or he could have taken active charge of the movement himself.

Throughout the trip from his headquarters to the left of the line he would not have been under fire for a minute and by his presence he could have insured the success of the advance.

At the time Stonewall Jackson's division had been driven back on the right and with Mansfield's and Sumner's corps the National troops engaged were gradually enveloping the Confederate left. One sharp charge, one rush order for three batteries of artillery and Lee's army would have been caught in a trap with 70,000 men surrounding their front and the Potomac river behind.



Equipped with a fast headquarters car McClellan could have reached the bridge in 15 minutes and taken charge of the field in person

It was a great opportunity and would have crushed the Confederacy three years before that event finally happened. It would have saved billions in money and hundreds of thousands of human lives, but unfortunately the automobile was not invented at that time.

On the Glidden Tour the cars moved slowly across this battlefield on their way from Gettysburg to Staunton. Practically all the way the caravan crossed fields that were once devoted to human slaughter. Of course it was vain to consider such things, but there was many an old soldier, or the son or grandson of an old soldier, who could not refrain from drawing some comparisons as to what the automobile would have meant to any of the commanders in the Civil War.

Starting at Gettysburg, every field presented some opportunity for discussing the problem of transportation as applied to military operations.

At Gettysburg, one of the tourists who commanded a company in Longstreet's army presented the other side of the picture. He said that if General Lee could have delayed Pickett's marvelous charge against Hancock's corps for 1 hour and could have continued the artillery battle with the Federal guns for that length of time when the charge should have been ordered it would have cut through the weakened line of blue and served as a wedge, making an opening by which the soldiers of Longstreet could have poured eastward toward Philadelphia after routing the National army.

But General Lee was several miles from the scene of the charge and the silencing of the Federal guns on the crest of the ridge deceived him as to the effect of the Confederate artillery fire. The charge took place as ordered and despite Lee's futile efforts to cause its delay for that one important hour. The Confederate commander realized after the arrangements had been made that the cannon fire had not been continued long enough and if he had had at his service a fast automobile to convey him or one of his aides to check the infantry charge until the guns had finished their work, there is more than a strong possibility that the cause of the South would have scored heavily. At this particular moment a great victory for Lee would have resulted in recognition of the South as a belligerent by one or more great European nations and its actual effect upon the North would have been profound.

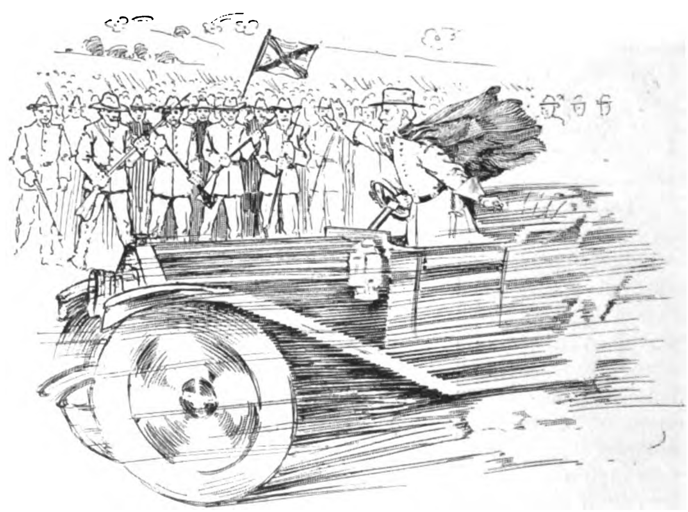
Crossing into Virginia and entering the Shenandoah valley, the opportunities for changing the whole political complexion of the nation if either side had been equipped with the ordinary touring cars of 1912 are impressive.

If General Jubal A. Early or General Sheridan had had a good fast touring car on the route followed by the Glidden Tour in 1911 the Confederacy would have been prolonged indefinitely or crushed promptly, depending upon which side possessed the car. Early could have captured Custer's division one day early in the final campaign in the Shenandoah if he could have had just 10 minutes' start in throwing one of his cavalry brigades between the Union troops and the Potomac river. An automobile circling to the rear could have conveyed the commander or his aide to the officer in charge of the brigade and started the well-planned movement to take Custer's soldiers that was only frustrated by a trifling delay on the part of the investing column. But Custer, alert to his danger, managed to take and hold the crossing of the Potomac long enough to allow his forces to escape from the superior force.

If this movement could have been accomplished Lee could have withdrawn Anderson's command, which had been sent to reinforce Early, and there would have been just that many more seasoned veterans to face Grant at Spottsylvania, Cold Harbor and the subsequent engagements. It also would have weakened Sheridan so that the ultimate destruction of Early could not have seen accomplishment in the way that actually happened.

The battle of Winchester would have proved the last fight in the valley if Sheridan could have ordered up his second line one hour earlier than he was able to do using mounted orderlies. This delay allowed Early to concentrate his forces and prevented a much worse Confederate defeat than was suffered.

If at this juncture General Lee had been able to double the reinforcements sent to Early there might have been a different story to tell, but owing to the lack of definite information in the possession of the Confederate commander, all of which could have been conveyed to him if there had been a good, fast automobile at hand, when Early's partial reinforcements did arrive and he started to drive Sheridan back through the valley his force was still so small that the Confederate leader showed he was not confident of accomplishing his purpose.



With a fast automobile Lee might have delayed Pickett's charge for one invaluable hour and avoided the Gettysburg reverse

Sheridan's main body of infantry was at Harrisonburg, the funny little village where the Glidden tourists were held up for speeding. The troops slowly retired toward the north, burning everything edible and destroying all property except the houses This continued to Cedar Creek, which lies some 20 miles south of Winchester, where Sheridan took up a strong position and awaited the approach of the enemy.

At this period of the campaign the authorities at Washington, unable to communicate at length with Sheridan, ordered him to appear at the capital for conference as to the conduct of the campaign. One automobile would have removed the necessity for this trip and made unnecessary the spectacular consequences that resulted from the absence of the commander.

It appears that the work of devastating the valley had been done so completely by the retiring Northern troops that Early could find little food for his men and horses and was forced to take immediate action or retire from the valley. In the still of the night Early moved out from his position to the south of Strassburg and before the Union troops were aware of this action, he had flanked the advance corps. The gray column faced to the flank and dashed in upon the unready Federals, rolling the disordered regiments together and throwing the whole army into such confusion that it seemed that the National army would be routed.

Sheridan had returned as swiftly as possible from Washington and had arrived at Winchester when he heard the dull booming of Early's artillery. Instantly the youthful general was in the saddle and dashing for the battle line.

Gallant and speedy as his great black charger proved himself, the progress of the general was necessarily slow. For a full hour Early's hungry soldiers plundered the captured position of the Union troops and occasionally desisted long enough to break some northern regiment that tried to retire in some sort of regular formation.

The Southern troops were about ready to plunge after the retreating enemy when the slight, young Sheridan mounted on a badly exhausted horse came to the mob of retreating soldiers and shouted orders for them to rally and face about. Sheridan was on time—just on time. He proved himself to be a resourceful officer and took advantage of all the facilities within reach.

He turned the tide of rout into a last desperate stand and while the front of battle held the charging Early the reserves rallied behind the line and then were added to the resisting column. At the critical moment the gray host began to waver and Sheridan ordered forward his cavalry, breaking the assaulting lines and sending Early whirling up the devastated valley.

But—if Sheridan had had one 40-horsepower automobile, like any of two score in the Glidden column. If that automobile had been lying at Winchester ready to do his bidding at a second's notice. Then Sheridan's ride from "Winchester 20 miles away" would have read somewhat differently.

Instead of riding his big black horse at the break-neck speed of 15 miles an hour, the general simply would have said to his chauffeur: "James, this is not Harrisonburg, hit it up a bit, we are due at Cedar Creek in 30 minutes.'

James would have touched the self-starting lever, dropped in his clutch and with a skillful shift of the gears would have been in high within 100 yards. Then, with James' foot on the throttle-lever, the General's car would have streaked it for Kernstown. The valley pike was in good shape in '64, the 4 miles could have been done in 5 minutes. From there to Stephens City, another 4 miles, there was a little more difficulty and it probably would have required 6 minutes. But to Middletown the road was found to be fine again and 4 miles would be reeled off in 4 minutes.

At Middletown, according to history, Sheridan met the first of the routed troops. He could have ordered James to slow down to a regular Mount Crawford gait while he rallied the panic-stricken soldiers, taking probably 1 minute to do so. Then James could hit it up once more to Strassburg, needing probably about 5 minutes to make the 4 miles, on account of the sharp grade and toll-gates to be found near that place. Here the general would be in the midst of the routed Northern troops and he could profitably spend 3 minutes in telling them how many different kinds of idiots they were, as he is reputed to have done when he rode into Strassburg in '64.

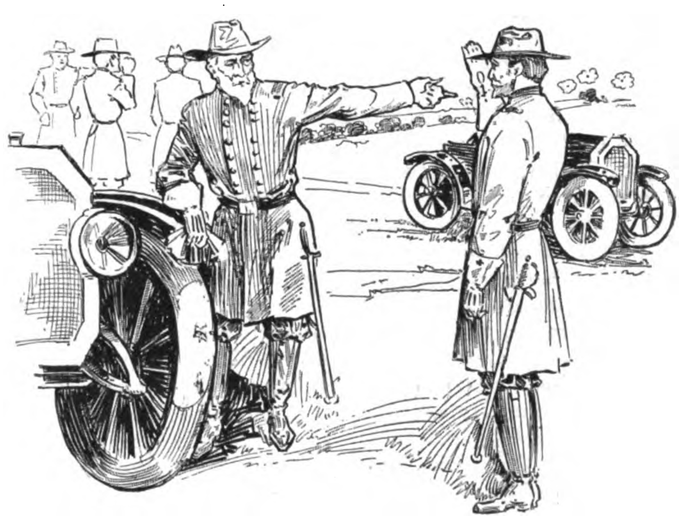
Cedar Creek and Early's famished hordes lay just about 4 miles to the South and the presence of the general in his automobile undoubtedly would have caused much more speed in rallying. Then the final dash might have occupied 6 minutes. The whole trip, rallying time and all, need not have been more than just 30 minutes, while in actual time Sheridan's ride took 2 hours.

Minutes are valuable in battle just as they are at a fire. It is the first 5 minutes at a fire that counts and it is the first hour in a battle, particularly when there is a chance to prevent a rout or to destroy an enemy.

If Stonewall Jackson had a car in 1861, there would be slavery in New York to-day if such a result had been the object of the campaign. If McClellan had an automobile at Antietam, Lee would have succumbed right there. If at nearly any one of fifty critical periods on either side during the war one of the commanders had been possessed of a standard touring car of 1912 type, the battle could have been reversed in its outcome, with all that such a result might mean. Naturally, in the next war both sides will be equipped with automobiles for messenger and other service and the advantage to be gained by sole possession of a car would be lost. Consequently the purpose of this fanciful article is to show the difference between transportation conditions in the Civil War and as they are to-day with respect to the automobile.

As a matter of cold, hard fact the Civil War never could have occurred if the automobile had been invented 50 years before the time it was.

History shows that almost all war has resulted from misunderstanding, and as the automobile demands good roads and as good roads make for better understanding among residents of different sections, the automobile would have served to prevent hostilities.



General Early, with a fast car at his disposal, could have overcome the 10 minutes' time which enabled Custer to slip from his net

During the recent Glidden Tour this point was well illustrated. The column contained practically half and half of Northerners and Southerners. In the North, the Dixieites learned that their countrymen of New Jersey and Pennsylvania did not grow horns and had no hoofs, while south of Mason and Dixon's line the Yankee tourists discovered that the people of Virginia, the Carolinas, Georgia and Florida were human beings with practically all of their own ambitions, hopes and aspirations.

Before, during and for 20 years after the close of the war there was no such understanding.

Of course, the Glidden Tour was only one small enterprise when compared with the sum total of intersectional communication based upon the automobile, and the lessons taught by it are of relatively small importance except as illustrations.

In the United States touring is classed among the highest grades of pleasure. It is growing more and more general each year and conjectures as to its future development are interesting.

In the days of Marco Polo nothing whatever was known about the outside world, except by a few sailors and adventurers, and as a result of the dense ignorance of that period every valley, river, and mountain that was not directly in contact with present observation was peopled with dragons, giants and spirits by the imagination of the inhabitants of every other valley, river, and mountain.

During the period of Roman supremacy, all other nations were deemed barbarians. Before the American Revolution the British monarch and most of his advisers considered the Americans criminals, descendents of criminals and generally inferior.

At the outbreak of the Civil War, the North considered the majority of the residents of the South as being ignorant, illiterate and of small importance, while the remainder were arrogant, overbearing, slave-owning aristocrats. On the other hand, the South looked upon the North as being hopelessly common and commercial, with a strong bent for stealing what the South considered personal property and a general tendency to interfere with things in which the North had no concern.

Senator Hoke Smith of Georgia, the leading advocate of good roads in the South, has stated distinctly on many platforms that the war could not have occurred if good interstate roads had been in existence. As the beginning of good interstate roads dates from the vogue of the motor car, and should be credited exclusively to the motor car, the influence of the car in spreading knowledge and as a deterrent to war must be acknowledged.

Another thing that the automobile has accomplished is in the way of colonization. To-day the South is dotted with communities less than 5 years old that have a distinctly Northern element in their population. The automobile has already demonstrated its service as a means of solving some of the problems of congested urban life. The very process of such demonstration has served to show the possibilities of country life and this has done a large work in bringing about the colonization referred to.

In southern Georgia and at many points in Florida there are new agricultural developments that may be credited in large measure to the automobile. One particular instance found in north Florida may be cited: The community referred to consists of 57 families, 32 of which came from the North. In this community there are 14 automobiles of various types and at Jacksonville it was learned that six other families are considering the purchase of cars next spring. Needless to say the roads of that particular community are different from those in other places along the sand belt.

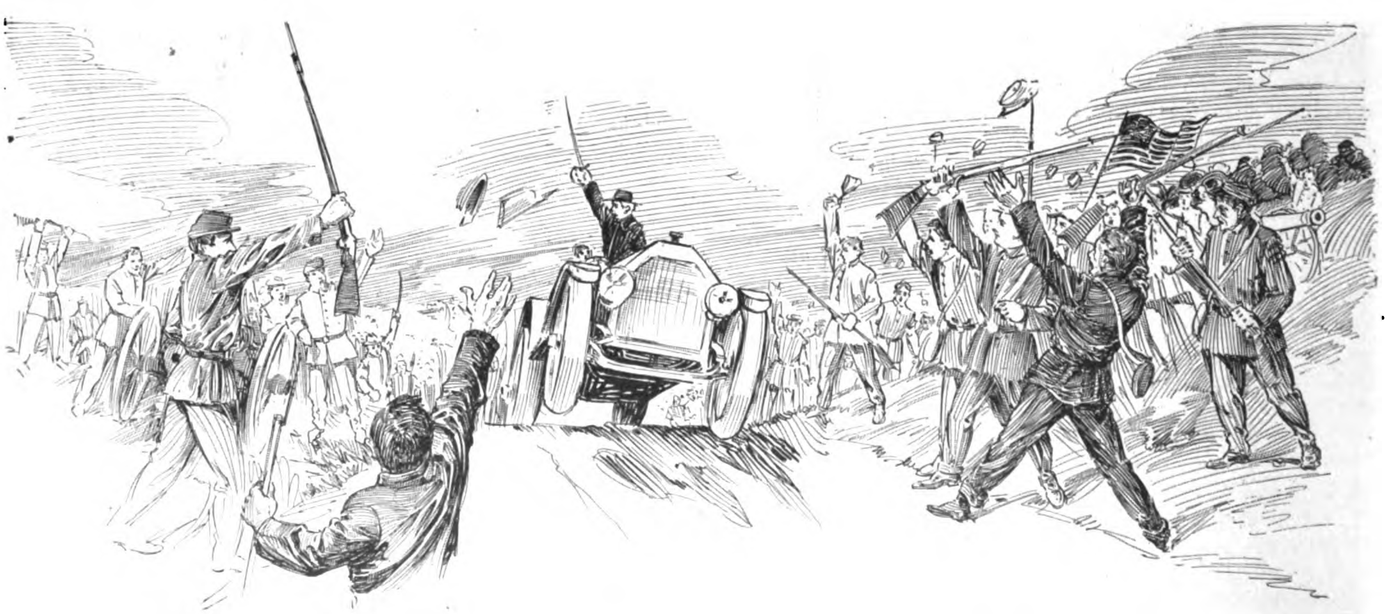
To sum up the whole situation in sequence: The mission of the automobile is worldwide. The automobile is useless without good roads. Therefore, the automobile brings good roads. Good roads mean easier communication between states, cities and communities. Therefore, the installation of good roads means quicker transportation of agricultural produce to market; added intelligence applied to the production of the fields; better and cheaper transportation of manufactured merchandise back to the communities and greater care in the manufacture of the goods demanded by the citizens of such advanced communities; more wealth all around and increased joy in living and working.

Italy and Austria Using War Automobiles

Italy, in getting upon her war legs, made it her first duty to equip her army with every modern convenience for the conduct of her campaign against the Turks in Tripoli. She has added the automobile to the general outfit, placing a number at the service of the Red Cross corps. But she is not going to stop here. She will add motor-ambulances to the original complement, thus facilitating the work on the battlefield.

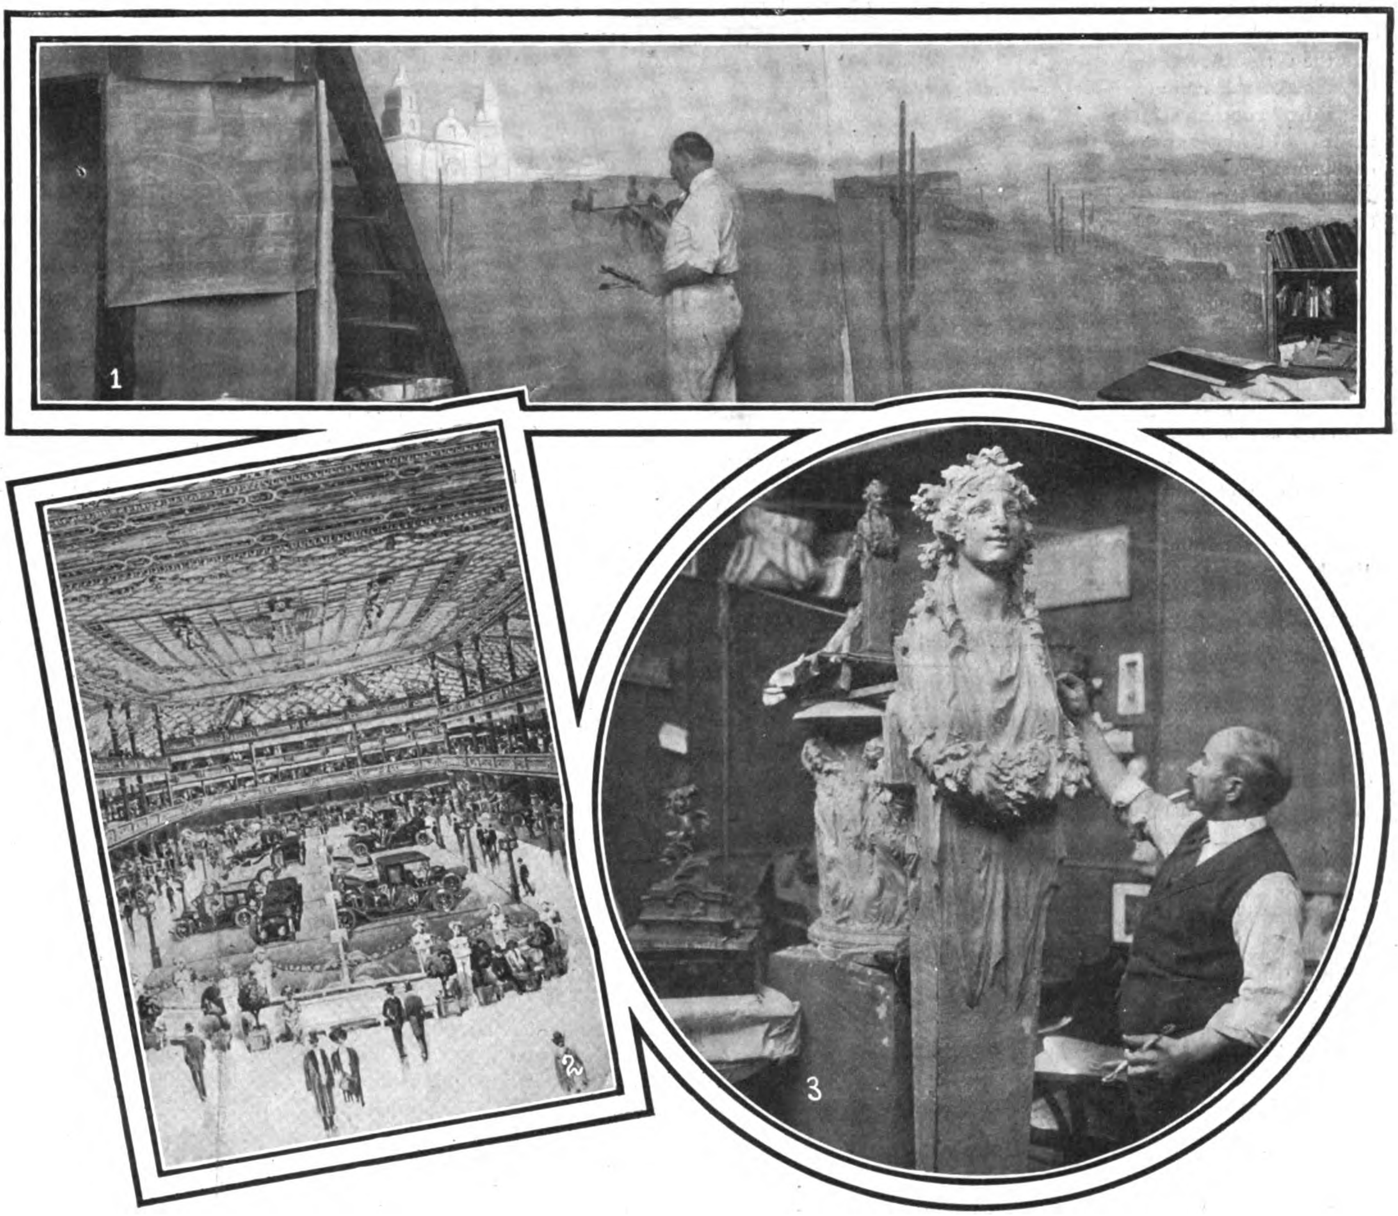
Austria's military budget for 1911, as laid before the delegations in Buda-Pest, embraced estimates for supplying the entire Austrian army with automobiles as a means of transport. Already the system has been made a certainty in some quarters, and it will not be a great while before the entire sixteen army corps of the Austria-Hungary forces will be traveling, whenever occasion demands, in automobiles. This decision was arrived at by the War Office at the close of a series of severe and exhaustive try-outs in Vienna and Buda-Pest, the trials having involved the use of automobiles with a carrying capacity of loads weighing from four to eight tons. After a considerable number of tests it was found that loads of this capacity were too heavy to be dragged over the country roads, bridges, the drains in the towns and the underground conduits. The War Office has finally adopted an automobile of two tons carrying capacity.

THE LOOKING-GLASS AS AN ACCIDENT PREVENTER—The authorities in Colchester, Essex, England, have inaugurated an odd custom by erecting huge mirrors at road junctions, with a view to reducing chances of accidents between automobiles coming from opposite directions. The mirrors are arranged at such an angle that drivers of motor cars and other vehicles are able to see any sort of an equipage coming around the corner.



Had automobiles been in vogue 50 years ago Sheridan's "20 miles away" could have been covered in almost as many minutes and the Union rout checked much earlier

All Motordom Awaits the Shows



1—Jean Paleologue, famous French artist, painting scene of Lower California for Garden decoration. 2—Center section of Garden, showing decorative scheme. 3—Philip Martini executing plaster creations for Garden Show

INTEREST in the approaching season of shows is the most potent force in the automobile world just at present. Touring is done for the time being, at least, as far as it is of national importance; sporting events are now history and even the excellent buying that has been noted throughout the fall has slackened perceptibly in anticipation of the new lines and new ideas that will be presented at the shows.

In some ways the decorative scheme that will be carried out at Madison Square Garden will be more wonderful than ever before. The formal lines of the Egyptian school will be followed, but in the coloring there will be more than a tinge of the oriental. The mural decorations will be exceedingly elaborate, the center piece being a California sunset. Martini, the celebrated sculptor, is in charge of the statuary designing.

The color plan of crimson and gold will lend itself in rich and striking ways to the general effect. With a big force at work on the preliminaries and a regiment of men waiting for the word to tear out the unnecessary portions of the interior of the building and replace them with the steel framework required, the big building can be quickly metamorphosed from a bicycle track and converted for the last time into the stage-setting for a great automobile show.

The bicycle racers hold forth there for the rest of the week but after the close of the races there is nothing of great importance scheduled before the show.

To an even greater extent than usual will the racing drivers be featured at the last Garden show. Mulford, Grant, Disbrow, Aitken, Wilcox, Harroun, Dawson, Patschke, Belcher, De Palma, Basle, Jagersberger and numerous other well-known racing pilots will be on hand to sell cars they have driven.

Over at the Palace final preparations are being pushed forward rapidly. Special emphasis will be laid on the commercial vehicles. A most interesting tabulation has been compiled by the management to show that trucks and delivery wagons propelled by gasoline engines are being used by 200 different branches of industry.

A vast invitation list is being prepared for the N. A. A. M. and Board of Trade shows. In the commercial car section it is said to contain from 80,000 to 100,000 names, all users or prospective purchasers of business vehicles.

An interesting tabulation is the one that deals with the classification of the cards left by visitors at the Garden show last winter and during the commercial week at Chicago. These cards number 3,300 and show that the visitors who left them belong to 53 general lines of industry which were purposely left broad in order to include them all. Of these the building and contracting branch was best represented with 247; metal manufacturing 194, and ranging down from there to flour milling, which was represented by 11 visitors. The professions were not considered in making up the list.

The Palace Show Poster

Importers' Salon Will Show 17 Foreign Cars

Seventeen different makes of foreign-built automobiles will be exhibited at the Importers' Automobile Salon, which is to be held in the Grand Ball Room of the Hotel Astor, New York, from January 2 to 10. Included in this number are, with one exception, every well-known foreign car which has achieved distinction either here or abroad. S. Kjeldsen, who managed the Salon last year and made it such a pronounced success, is at the helm again this season.

The forthcoming exhibition will be strictly a drawing room affair and not an industrial show. Commercial vehicles are excluded and a leading feature will be the magnificent bodies, mounted on the various cars which will exemplify the latest productions of the famous coachbuilders of Europe and America. Four of the latter, by the way, will have separate exhibits.

Over 20,000 square feet of floor space is available in the ballroom and the decorations are superb.

The various makes of automobiles to be exhibited are the C. G. V., Darracq, De Dion Bouton, Panhard and Renault from France; the Benz, Mercedes and Opel from Germany; the Isotta, Itala, Lansia and S. P. A. from Italy; the English Daimler and Napier from England; the Metallurgique and Minerva from Belgium, and the Pic-Pic from Switzerland. The body builders exhibiting are Demarest & Co., the Holbrook Co. and Quinby & Co.

Philadelphia Show Spaces Allotted

PHILADELPHIA, Dec. 9—The results of the drawings for space at Philadelphia's eleventh annual automobile show were announced yesterday, showing that 43 dealers will be represented during the initial week, with a total of more than 50 different makes of pleasure cars. Of this number, according to present plans at least, 22 companies will be allotted space at the Third Regiment Armory, Broad and Wharton streets, and 21 at the First Regiment's building, Broad and Callowhill streets. In all 35,000 square feet of floor space will be utilized to accommodate applicants and present indications point to close quarters for some of the would-be exhibitors. For example, a nearly equal division of space in each armory was made for the gasoline pleasure cars, the First Regiment structure containing 16,500 square feet, all of which will be for these cars, while 15,500 square feet will be devoted to the same purpose in the Third Regiment Armory. The latter building is the larger of the two, containing 18,500 square feet, but 3,000 square feet has been set aside for the accessories exhibit, the drawings for which will be conducted next week. As the space is necessarily limited, the demand is expected to far exceed the accommodations for the display of the many little necessary adjuncts to safety and comfort.

The same difficulty, in an aggravated form, confronts the show committee of the Philadelphia Automobile Trade Association regarding the awarding of space for the exhibition of electrics and commercial vehicles during the second week, the truck show in particular promising to gobble up all the available space—and more.

The list of exhibitors assigned space and the cars which they handle shows the following: Third Regiment Armory: General Motor Car Co., Lozier; Automobile Sales Corporation, Peerless & Cadillac; North Philadelphia Automobile Station, Knox; Winton Motor Carriage Co., Winton; Gomery-Schwartz Motor Car Co., Hudson; Oldsmobile Co. of Pennsylvania, Oldsmobile; Packard Motor Car Co., Packard; Paxton-Crumley Automobile Co., Warren-Detroit; L. J. Bergdoll Motor Co., Bergdoll; Automobile Co. of Philadelphia, Marmon; Longstreth Motor Car Co., Alco; Foss-Hughes Motor Car Co., Pierce-Arrow; Stoddard-Dayton Automobile Co., Stoddard-Dayton; Fiat Automobile Co., Fiat; Chalmers-Hipple Motor Co., Chalmers; Chadwick Engineering Works, Chadwick; Pope-Hartford Sales Corporation, Pope-Hartford; The White Co., White; Mitchell-Lewis Motor Co., Mitchell; Abbott-Detroit Motor Co., Abbott-Detroit; A. G. Spalding & Brother, Stevens-Duryea; Johnson Motor Car Co., Haynes.

Those exhibiting at the First Regiment are as follows: Gawthrop & Wister, Elmore; Ford Motor Co., Ford; Hupp Corporation, Philadelphia Branch, R. C. H.; Overland Motor Co., Overland; G. H. Gantert, Stearns and Selden; Tioga Auto Co., National and Hupmobile; Locomobile Co. of American, Locomobile; W. Wayne Davis Co., Everitt; E. C. Johnson Co., Reo and American; Continental Motor Car Co., Henry and Speedwell; Studebaker Bros. Co., Studebaker, E-M-F and Flanders; United Motor Philadelphia Co., Maxwell and Columbia; Motors Distributing Co., KisselKar; D. Walter Harper, Cameron; Oakland Co., of Pennsylvania; Oakland; Thos. B. Jeffery Co., Rambler; Stanley Motor Carriage Co., Stanley; Mercer Automobile Co., Mercer; Cartercar Motor Co., Cartercar; Standard Motor Car Co., Velie; Eldredge Co., Garford.

Additional Space Necessary at Detroit

DETROIT, MICH., Dec. 11—With over 50,000 square feet of floor space, the Detroit Automobile Show, January 22 to 27, at Wayne Gardens will be one of the largest local shows in this country. Announcement is made at the office of the D. A. D. A., 501 Bowles building, that an annex will be built to extend across Front street and over a large piece of vacant property on the opposite side of the street. This temporary building will be 108 feet wide and 165 feet long, giving 17,820 square feet of floor space. The Wayne Gardens contain 33,180 square feet. The new building will be well heated and brilliantly lighted and the decorations will be on a par with those in the Wayne Gardens.

The city officials were appealed to for permission to build the annex and without any hesitation agreed unanimously, believing that Detroit should rank with the other cities of the country in its show and that by allowing the closing of Front street they will be giving their assistance in the matter.

The new building will be of single story construction. It will have side windows, giving ample light in the day time. At night it will be brilliantly lighted by electric arc lamps.

Coming, as it does, between the New York shows and the Chicago National Show, Detroit's automobile exhibit holds a strong strategic position in the circuit of American shows. Many Detroit exhibitors who have articles to show are unable to prepare themselves for the opening exhibit at New York and their wares are first seen in the Detroit exhibition. Throughout the country, dealers and agents generally are looking to Detroit for new cars, for new trucks, and for new accessories and, in being able to view a general exhibit in Detroit of the industries of the city and at the same time visit the manufacturers of this city, they find the Detroit show of much practical value.

Syracuse Show to Follow Boston's

SYRACUSE, N. Y., Dec. 11—In the State Armory the Syracuse Automobile Dealers' Association has been utilizing at its annual winter exhibitions 25,000 square feet of space, besides additional space in adjacent buildings. This question of space has become a serious one, as the association could readily use 50,000 square feet, were that space available. The association is hoping that public-spirited citizens will erect a building ample enough for future purposes of the association and for similar events.

At a meeting of the association held this week the date set for the fourth annual Syracuse Automobile Show was March 12 to 16, inclusive, immediately following the Boston show. Already the whole of the exhibition space has been practically spoken for by dealers, and many must inevitably be disappointed. Special attention will be paid to the decorations and musical program, and, coming as it does immediately following the close of the Boston show, it will be possible to secure many of the special show exhibits sent out by the various manufacturers. A special express train will probably be secured to bring selected Boston exhibits here.

The officers of the association are: C. Arthur Benjamin, Packard representative, president; M. W. Kerr, Everitt, vice-president; John R. Valentine, Chalmers, treasurer; W. R. Marshall, secretary and show manager; directors, Sam Silverman, Jr., Ford; George H. Norris, Cadillac; W. R. Shaw, Reo. The office and headquarters of the association are in the Onondaga Hotel. Mr. Shaw, of the Reo agency, assumed a director's post to replace E. P. Horton, of The United Motors Company, who has removed to Atlanta, Ga.

Cincinnati Show in Music Hall

CINCINNATI, O., Dec. 11—The Retail Dealers' Association annual show committee reports that applications for space are coming in more rapidly than was expected and that additional features looking to the entertainment of the guests of the association from out of town are now contemplated, including a concert program with vocal selections by artists of national repute. The past shows are to be eclipsed by the event of the week of Washington's birthday and the fact that the association is so fortunate as to have the great Cincinnati Music Hall this year for show purposes has stimulated the committee to make the event one of great social importance as well as an exposition of the progress of the motor world in the central states. Commercial vehicle manufacturers are coming to the front with applications on account of the importance given this class of automobiles by the dealers' committee in arranging special show dates following the pleasure vehicle show and many more types of this class of cars will be shown here this year than ever before.

The Cincinnati show management will, as usual, give much attention to the setting of displays and has secured the highest authority obtainable as regard the artistic and floral features of the coming show.

Canadian National Shows Progressing

Judging by the applications received, great interest is being shown by manufacturers of automobiles in the two Canadian national automobile shows to be held in Montreal and Toronto, on dates February 3 to 10, and February 21 to 28, respectively.

Manager E. M. Wilcox, 123 Bay St., Toronto, states that almost every American car seems to be now represented in Canada, and there will undoubtedly be a large increase in the exports of automobiles from the United States to Canada in 1912, although the increase last year was almost double that of the year before. The Armory has been secured from the Dominion Government for the Toronto show and the Drill Hall for the Montreal show.

International Rubber Show in 1912

Sir Henry Blake, G. C. M. G., will act as presiding officer of the first International Rubber Exposition to be held in the United States and which is scheduled for September, 1912. Practically every important rubber industry in the world will be represented and the scope of the exposition may be judged from the fact that over seventy leading men connected with various branches of the industry in foreign lands have accepted committee assignments for important work before and during the exposition. The show will be staged in the new Grand Central Palace under the management of the International Exposition Co. of which Samuel A. Miles is a director.

Atlanta May Promote a Show

ATLANTA, GA., Dec. 9—The Atlanta Automobile and Accessory Association has started two campaigns which should result in the organization of a state association of automobilists and a dealers' show in Atlanta.

A series of meetings has been held with a view of working up interest in the much-needed state association. The most recent one was on Monday, December 11.

Committees are now working through the field to find out the prospects for a successful dealers' show. Atlanta has an ideal place for such an exhibition in the Auditorium-Armory, where the first Southern show under national auspices was held.

M. and A. M. Show Week Meetings

In connection with the activities of the show season next January the Motor and Accessory Manufacturers have announced the following meetings: Executive Committee, Tuesday, January 9, at 10 a. m., at the association's offices, 17 West Forty-second street; Board of Directors, same day and place at 11 a. m.; Banquet Committee, immediately following that of the Board of Directors; ninth annual meeting, Wednesday, January 10 at 10.30 a. m., at the Waldorf-Astoria; annual banquet, grand ballroom, Waldorf-Astoria, Thursday, January 11, at 7 p. m.

Rochester Space All Disposed Of

ROCHESTER, N. Y., Dec. 11—The annual show of the Rochester Automobile Dealers' Association, will this year for the first time be held in the State Armory, one of the largest exhibition display spaces in the State.

The committee in charge is as follows: F. W. Peck, chairman; J. C. Dryer, secretary; W. C. Barry, Jr., A. F. Crittenden, C. E. Hartson, A. R. McKenney, S. C. Babcock, F. R. Luescher, C. E. Sager, G. F. Bauer, Arthur McNall, A. V. Hart and D. F. Garber. Colonel C. A. Simmons, assistant adjutant-general of the state, who managed Rochester's show two years ago, will be in charge.

Showing arrangement of spaces in Madison Square Garden, upper balcony, Exhibition Hall and Concert Hall

News of Other Local Shows

MILWAUKEE, WIS., Dec. 11—The opening night of the fourth annual Milwaukee automobile show under the auspices of the Milwaukee Automobile Dealers' Association in the Auditorium from January 13 to 19, inclusive, will be Milwaukee Automobile Club Night and the 600 members of the club will be the special guests of the dealers. Sunday, January 14, will be Owners' Day; January 15, Interurban Day; January 17, Merchants' and Manufacturers' Day, on which commercial vehicles will be featured; January 18, Wisconsin Automobile Dealers' and Wisconsin State Automobile Association Day, and the closing day, January 19, will be Society Day. The motor club, which conducted the first two Milwaukee shows, is co-operating with the Dealers' Association to make the fourth show a huge success.

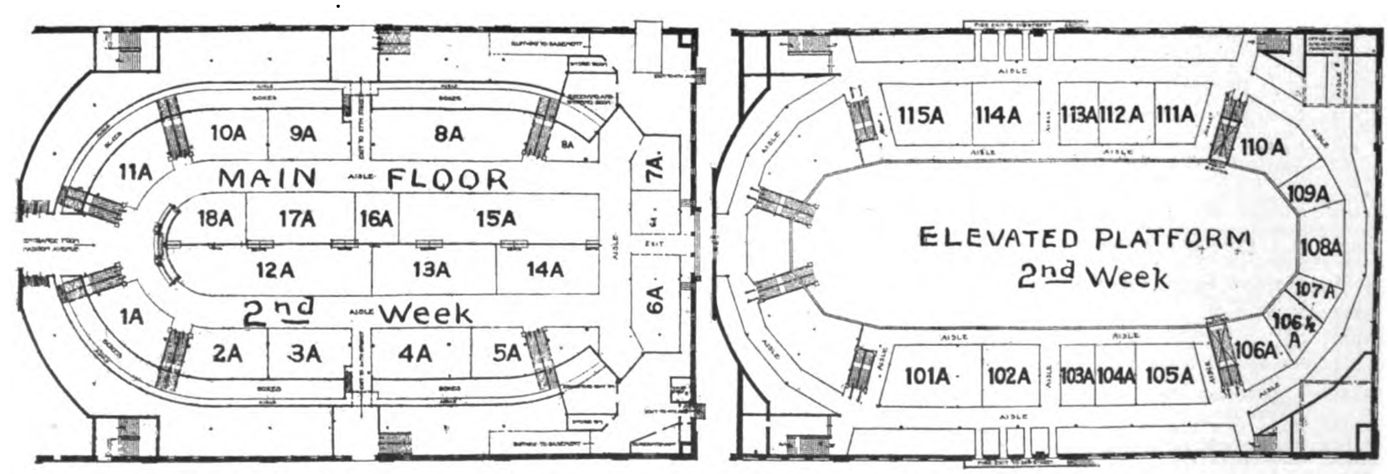
LOUISVILLE, KY., Dec. 11—The fifth annual exhibition of the Louisville Automobile Dealers' Association will be held February 21, 22, 23 and 24 in the First Regiment Armory, which covers more floor space, it is said, than any other building in the South. The 1912 show is scheduled a month earlier than it was held last year. The committees in charge of the exhibition in 1911 did their work so well that they have again been chosen to make arrangements for the coming show, and look after all the details connected with the displays.

TIFFIN, O., Dec. 11—The dates for the second annual *Advertiser* Auto Show, under the auspices of a local organization have been definitely fixed for March 6 to 9 inclusive. Space is now available.

Prof. Warren S. Johnson Dead

MILWAUKEE, WIS., Dec. 11—Prof. Warren S. Johnson, president and treasurer of the Johnson Service Co., one of the largest builders of pleasure and commercial cars at Milwaukee. Wis., who died at Los Angeles, Cal., on December 5, after an illness of two years, was a noted inventor and designer and probably the first man to propose and execute the idea of using the motor vehicle in the postal service.

The funeral was held at Los Angeles on December 7 and the remains were cremated, at Prof. Johnson's request.



How the commercial exhibitors at the Garden will be installed during the second week of the show

Late General and Trade News

ATLANTA, GA., Dec. 7—The awards in the Tour Around Georgia, which virtually ended in Atlanta, December 2, have just been made public. The reason for the delay was the fact that while most of the cars finished in Atlanta a few machines which joined the tour on the first, second and third days of the run had to go back to their starting points before they completed the circuit and no awards could be made until all had finished and until all the checkers' reports had been mailed to the referee.

The two special prizes offered for consistent running and for sticking most closely to the time card were awarded by Referee Connally. First prize was given to the Velie roadster, entered from the Atlanta Velie branch, while the second prize went to the Flanders team. The hard luck cup, offered by the Atlanta Ad-Men's Club, had previously been awarded, on a vote of the contestants, to W. G. Southerlin whose Overland was continually in hot water.

The other prize winners, the entrant and the amount of prize money received follow:

Class A (Cars Costing $2,500 and Over)

No. 3—Dr. J. C. Luke, Ocila, Ga., Ohio	$108.33
No. 15—T. C. Lauren, Atlanta, Packard	108.33
No. 21—Frank G. Corker, Dublin, Ga., White Gas	108.33
No. 23—Ralph Walker, Atlanta, National	108.33
No. 37—Evelyn Harris, Atlanta, Thomas Flyer	108.33
No. 53—Muchalu Cigar Co., Americus, Ga., Marmon	108.33

Class B (Cars Costing $1,600 to $2,500)

No. 1—Atlanta Ad Men's Club, Imperial	$50
No. 2—Ohio Motor Car Co., Cincinnati, Ohio	50
No. 5—Jake W. Paulk, Ocilla, Ga., Ohio	50
No. 11—Atlanta Chamber of Commerce, Cole 30-40	50
No. 19—Velie Motor Vehicle Co., Atlanta, Velie	50
No. 22—Sam Bashlinski, Dublin, Ga., Chalmers	50
No. 28—U. S. Fuller, Culloden, Ga., Cadillac	50
No. 31—W. A. Ayash, Americus, Ga., Overland	50
No. 36—G. W. Varn, Valdosta, Ga., Cadillac	50
No. 40—F. G. Edwards, Albany, Ga., Chalmers	50
No. 43—W. B. Cummings, Atlanta, Buick	50
No. 46—Gulf Refining Co., Atlanta, Mitchell	50
No. 60—B. T. Bowers, Cannon, Ga., Case	50

Class C (Cars Costing from $1,000 to $1,600)

No. 6—W. E. Sawyer, Americus, Ga., Overland	$130
No. 14—Miss Regina E. Rambo, Marietta, Ga., Overland	130
No. 30—Holmes Bros., Culloden, Ga., Buick	130
No. 42—Steve R. Johnston, Atlanta, Buick	130
No. 56—Trio Laundry, E. H. Wilson, Atlanta, E-M-F	130

Class D (Cars Costing $1,000 or Less)

No. 33—E-M-F Company, Atlanta, G. W. Hanson, Manager, Flanders	$162.50
No. 34—E-M-F Company, Atlanta, G. W. Hanson, Manager, Flanders	162.50
No. 35—E-M-F Company, Atlanta, G. W. Hanson, Manager, Flanders	162.50
No. 48—Georgia Motor Car Company, Atlanta, Liberty Brush	162.50

Traction Company Selling Electric Cars

A new era in motor car selling in Milwaukee, Wis., began on December 1, when the Milwaukee Electric Railway & Light Co., one of the largest and strongest public service corporations in the United States, became selling agent for the Rauch & Lang electric cars. The former agent was the Welch Bros. Motor Car Co., which has sold its Packard business to the Packard Motor Car Co., of Chicago, to enable the Welch brothers to care for their late father's vast estate. The Electric Company, as the M. E. R. & L. Co. is generally known, has as territory the city of Milwaukee, Kenosha, Racine, East Troy, Burlington, Waukesha, Oconomowoc, Watertown and all points reached by its interurban lines, in addition to the contiguous territory. John I. Beggs, former president and general manager of the company and mainly responsible for its remarkable growth and prosperity, purchased a Rauch & Lang electric several years ago, after an extensive study of electric cars, and several of these cars are now used by officials and superintendents of the traction company. Recently the new management of the Electric Company established a large private garage for its numerous light and heavy trucks, including gasoline and electric cars, used for transportation and repairs. The sales department is at the Public Service building, the $2,000,000 terminal of the traction company, and the show rooms at the M. E. R. & L. Co. garage, 451-453 Broadway.

Bay State Association's Annual Banquet

BOSTON, Dec. 11—The annual banquet of the Bay State Automobile Association at the Hotel Somerset this evening was the most successful motor affair of a social nature that has ever taken place in Boston. There were about 250 members and guests present.

At the head table President E. A. Gilmore had the center position and on either side of him were the following guests: Mayor John F. Fitzgerald, of Boston, President George W. Smith, of the Boston Chamber of Commerce, President George A. Coleman, of the Associated Advertising Clubs of America, Ex-Chairman Harold D. Parker, of the Massachusetts Highway Commission, Col. William D. Sohier and Frank D. Kemp, of the Highway Commission, President Lewis R. Speare, of the Massachusetts State Automobile Association, former president of the A. A. A., President John H. MacAlman, of the Boston Automobile Dealers' Association; President C. F. Whitney, of the Boston Commercial Vehicle Dealers Association, Chairman A. G. Batchelder, of the American Automobile Association executive committee, President Alvin E. Bliss, of the Malden Automobile Club, President A. E. Converse, of the Winchendon Automobile Club, President W. H. Chase, of the Leominster Automobile Club, President William N. Appleton, of the Haverhill Automobile Club, President John S. Harrington, of the Worcester Automobile Club and Secretary James Fortesque, of the Massachusetts State A. A., and many others prominent in automobile circles.

President George W. Smith, of the Boston Chamber of Commerce, and President George A. Coleman, of the Associated Advertising Clubs of America were among the speakers of the evening. President Hugh Chalmers, of the Chalmers Motor Car Company, was to have delivered his address upon "Salesmanship," but was prevented by a sudden illness.

Quaker Dealers Elect New Officers

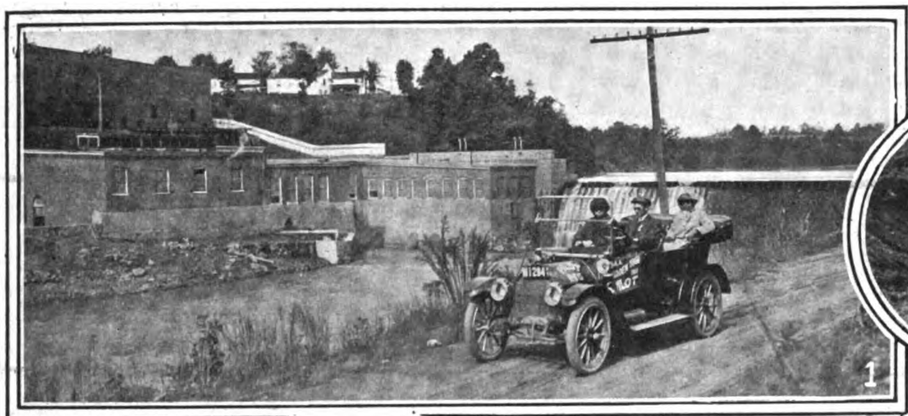
PHILADELPHIA, Dec. 8—At the annual meeting and election of the Philadelphia Automobile Trade Association on Wednesday at the organization's headquarters, southwest corner of Broad and Callowhill streets, the following officers were elected for the ensuing year:

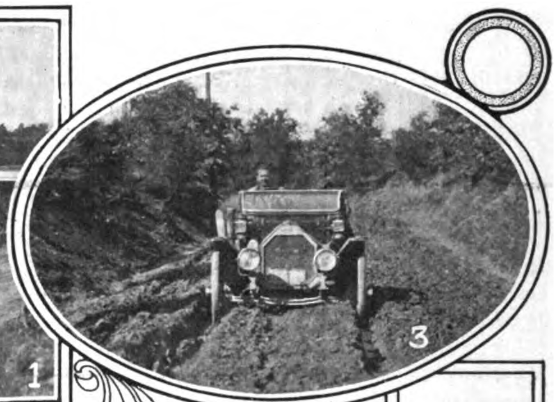
Louis C. Block, manager of the Philadelphia branch of the Ford Motor Company, president; William P. Herbert, of the General Motor Car Company, handling the Lozier car, vice-president, and F. W. Eveland, of the A. G. Spalding & Brother Company, agents for the Stevens-Duryea, re-elected treasurer.

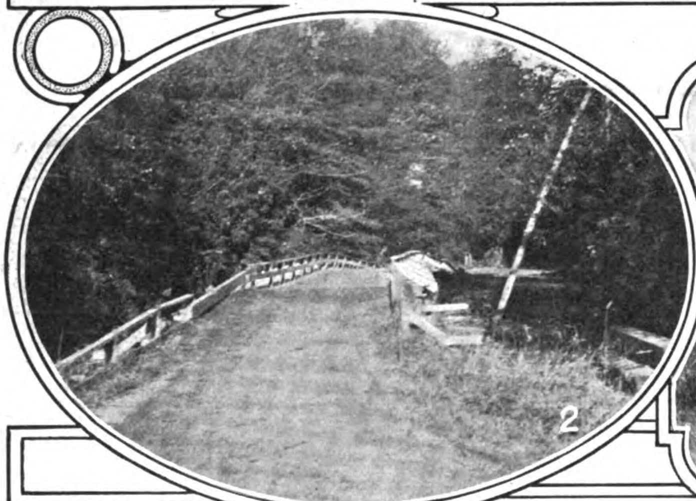
R. M. Cook, manager of the Automobile Sales Corporation (Peerless and Cadillac), and H. H. Coale, sales manager of the Autocar Company, were elected members of the Board of Directors, while W. Wayne Davis, head of the W. Wayne Davis Company (Everitt), and J. C. Bartlett, of the Woods Electric Company, were chosen members of the Committee on Admissions.

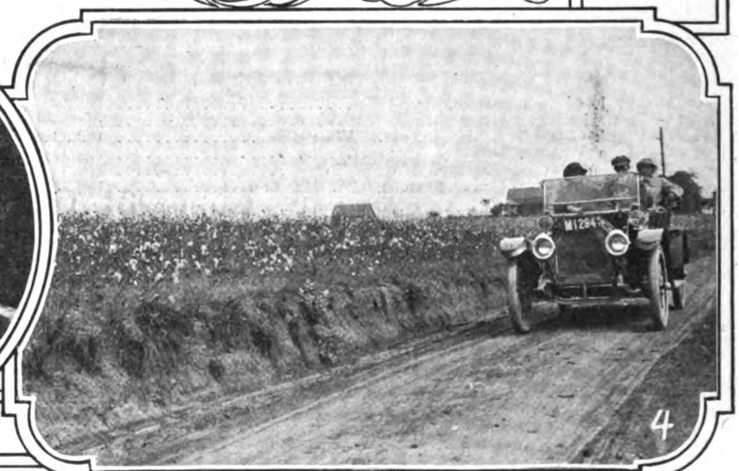
All of the new officers of the association are well and favorably known in automobile trade circles, not only in Philadelphia, but throughout the East.

A Jaunt Through South Carolina,









1—Where the Pacolet River is harnessed to turn the cotton mills at Converse
2—Bridge building is no fine art here, but is needed only occasionally
3—The worst spot found in South Carolina and not so very bad after all
4—In the heart of Cotton's kingdom, 7 miles from Greenville

WHEN the Glidden Tour crossed South Carolina a road had been selected for the caravan to follow that touched only the extreme western portion of the state. The topography of South Carolina is level generally, and the nearer one approaches the Atlantic seaboard the flatter and more swampy it is.

Within the state the highway followed was 134.3 miles long, all of which is more or less improved. The country raises cotton as a staple and corn, turpentine and lumber incidentally. The scenery lacks the grandeur of the Virginia hills, but the roads are an improvement over those of the section south of Roanoke.

There was a bumper cotton crop produced in South Carolina this season and part of it was marketed at good prices. However, a majority of the farmers and local dealers and ginners have not learned the use of short sales in the market when cotton is high, and consequently did not take advantage of the high level of prices that prevailed for a part of this season.

As a result, wherever in the South cotton is the chief article to be marketed there is considerable depression of spirits. This is all so unnecessary that it caused much comment among the Northern business men who took part in the tour. If the cotton producers, as soon as they found out that they were going to have a big crop, had sold the market for delivery, say, in January or March and taken contracts to deliver their goods at the level of prices that obtained earlier in the year the condition of finances in South Carolina and elsewhere in the South would have been vastly different from what it is now.

If cotton costs 8 cents a pound to grow and market, and the present level is not far above that figure, the profits of the cotton planter must be small. If, on the other hand, he had sold short in the market for delivery in January at 14 cents a pound his profits would have been material.

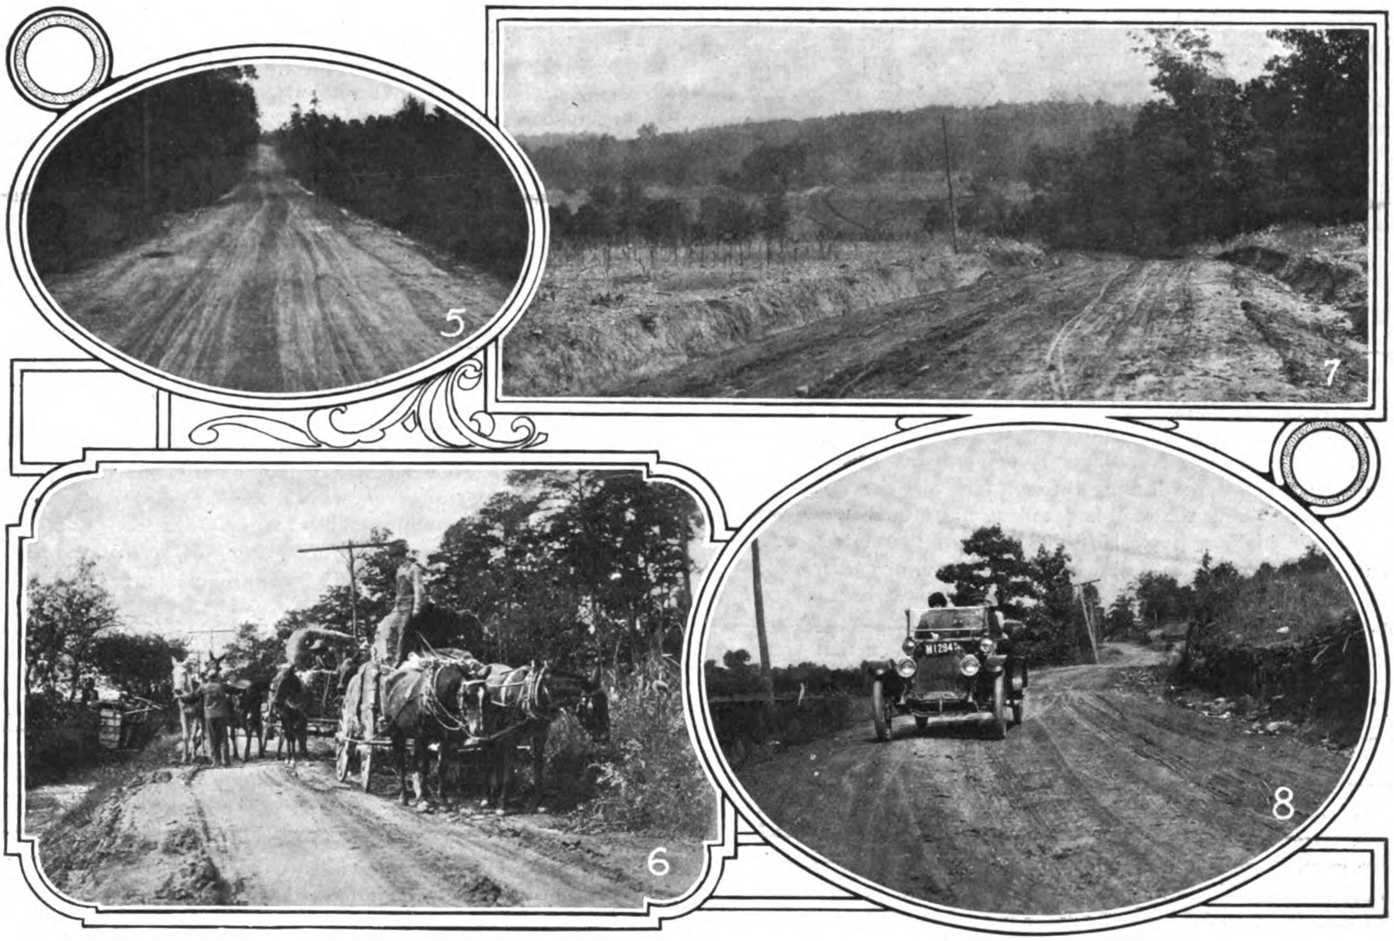
As commercial conditions affect the automobile trade vitally, the cotton market is important to the industry, as regards its southern distribution. The result is quite apparent in the scarcity of new automobiles to be seen on the South Carolina roads.

The highways of South Carolina are mostly built of yellow clay, mixed with varying proportions of sand. As a general rule, they are carefully graded and drained, and in particular spots finely improved. Actual macadam is scarce, but the general average of excellence in the ordinary country roads is higher than that found anywhere along the route to the north.

Of the 134.3 miles covered by the route across the Western end of the state, not more than 20 miles is macadamized and not more than 20 miles can be classed as ordinary road.

The route traverses a section rich in historical lore, passing the battlefield of Cowpens, where the British dragoons and infantry were badly defeated by the patriot forces and driven northward, where they received several other trouncings at the hands of the redoubtable Greene and Morgan. The road was also used

Where King Cotton Holds Full Sway



5—A fine stretch of road leading through the battlefield of Cowpens
6—Average roads near Blacksburg used for heavy cotton traffic
7—New road into Greenville. This one has just been finished
8—The typical South Carolina road, just after leaving Gaffney

to some extent by General Sherman in his famous march to the sea in 1864.

The road enters South Carolina just south of Grover, and the excellent graded road of North Carolina is continued. There are some stiff grades to be covered rounding the foothills of Whitaker Mountain, about 4 miles from the state line, and there is a ford to be crossed before reaching Blacksburg, the first settlement to be passed in the state.

South of Blacksburg the road passes into heavy pine woods, emerging for a moment to cross Broad River and then plunging into the woodland country again on the south side of that stream. There are two considerable grades before reaching Cherokee creek and after that the character of the road changes. Yellow clay takes the place of the red clay that composed the groundwork of practically all the roads to the Virginia line.

The country contains more sand and for ordinary country roads the mixture of sand and yellow clay is ideal. Gaffney, a lively little city, lies 16 miles south of the state line. On leaving this place the road crosses a low range of hills and enters the only really rough spot in the whole way across the state. Even in wet weather this road is not much of an obstacle to the passage of automobiles, as the sand contained in the road-surfacing material gives traction under all conditions. After passing Irene Creek there are heavy grades at intervals clear to Cowpens, a distance of 10 miles.

Most of this distance is through the nearest approach to a wilderness to be found south of Roanoke, but the rolling hills give some evidence of cultivation and as one approaches Cowpens the cotton fields stretch away as far as the eye can reach. The population of this part of the state is sparse and even negroes are not common. But when the vicinity of the old battlefield is reached conditions grow better, and after crossing the Pacolet River, which has been dammed and used to furnish power for extensive cotton mills at Converse, the country improves and at Spartanburg, a fine city of 18,000 inhabitants, there is every evidence of prosperity.

Spartanburg is rated as the third city in point of size in South Carolina and is reckoned to be the second in the United States in the production of cotton-seed oil, besides being in the center of the second largest cotton producing section in the world. Its fertilizer industry is said to produce $1,500,000 a year.

Leaving Spartanburg a fine macadam road leads southward almost to the crossing of the north fork of the Tiger River. From that point to the middle fork of the same stream the way is through vastly productive cotton fields over good clay roads upon which much work has been done. This is about 52 miles from the state line.

Duncan is the next town of any size to be met with and it is also the largest town on the road between Spartanburg and Greenville, 36 miles. But, in spite of this, Duncan is a mere ham-

Widening new road near Blacksburg. Note the road roller and broken stone

let located on the railroad that connects the two larger cities.

At the crossing of the Tiger river improved roads are again found, the main pike leading through Greer to the south. From the river to Greer the road is excellent and after leaving Greer a fine, level highway typical of the roads of the state is encountered. This continues, following the railroad, or rather followed by the railroad, into Greenville. This section of the state is very rich agriculturally. The soil is sandy loam based upon clay, and while it is considered excellent for everything that grows in warm temperate climates it is devoted almost exclusively to the culture of cotton.

The city of Greenville is located at the foot of the Blue Ridge hills. It is the largest cotton manufacturing center in the South, possessing about fifty large mills, the power for which is derived from the Reedy river. It is close to the summit that divides the flat eastern slope from the more rugged territory that lies to the west.

From Greenville to Piedmont on the Saluda river, about 12 miles, the cotton fields grow a trifle monotonous and the hills and woods to be found after crossing the Saluda are welcome to the eye, but do not endure for long. Some of the finest roads in the state are to be found south from Greenville, the surfacing of sand-clay, carefully smoothed and graded, rivaling macadam in its riding qualities.

It is said that five years ago only about one-fifth as much of a load could be drawn over these roads as can be transported over them to-day in wet weather.

The Heart of the Cotton Belt

This section is in the heart of the cotton belt and each mile south finds the cotton whiter and the negroes blacker than they were the last mile back on the road. In Virginia the negroes and the cotton were about of a shade. In North Carolina the cotton was fairly white and the negroes were coffee colored. In the northern tier of counties in South Carolina the cotton was pure white and the negroes black and shiny. But south of Greenville the cotton is glistening snow white and the coons lose even their shine of countenance and are deep Cimerian sable without mitigating circumstance unless one throws a small coin among a group along the roadside. Then there is a swift metamorphosis. Faces crack open and enough ivory is shown to relieve the color scheme materially.

The attitude of the negroes in South Carolina will be found to differ sharply from their usual attitude further north. They are exclusively devoted to agriculture and many among them work land on shares, while a very few own the property they till. Toward the born Southerner the South Carolina negro assumes an attitude of great respect. But if he suspects that the white man comes from the north, particularly from New England, there is sure to be some amusement.

During the Glidden Tour, when the cars were covering this stretch of country, one of the drivers, Thomas Costello, a native of New York, manifestly unfamiliar with the southern conditions, acknowledged the salutes of a party of negroes just outside of Piedmont.

"How are yuh?" inquired Costello genially as his car moved on.

"How ah yu, brothah?" came the response for the crowd, voiced by a huge black woman.

If she had suspected that her white brothah was a citizen of South Carolina she would rather have been stricken dumb than to have made that answer.

The road scene is not changed and lacks much interest to the ordinary tourist clear to Anderson. The roads continue fine all the way in. Anderson is the county seat of Anderson county and is a well-built place, the chief, almost the sole, industry of which is cotton manufacturing. The county raises more cotton than any similar division east of the Mississippi and is exceeded only by some of the Texas counties that are much larger in territorial area than Anderson county.

Some Rough Country Near Georgia Line

Away on the horizon, the cool shadows of the Blue Hills can be seen, but the city itself is situated in the midst of a flat country where cotton is emphatically king. The city of Anderson has no workable waterpower within the city limits, but the county is well supplied with potential forces for manufacturing. So far only a small amount of this power has been developed, it being estimated that there is something like 125,000 horsepower that is not at work. Anderson county raises not less than one bale for each inhabitant and the mills work up 30,000 bales in excess of the annual production of the county.

Lincoln Way Prospects

HARRISBURG, PA., Dec. 11—In accordance with the plans of the Sproul good road bill passed at the last session of the legislature for the building of good roads in Pennsylvania, State Highway Commissioner Bigelow is awaiting the action of the present Congress in regards to the Lincoln way before he begins work of building the road from Gettysburg to Harrisburg.

He declares if the way is authorized he will continue the highway to Harrisburg as a double roadway with grass plot and trees in the center. He is hopeful of the way and desirous of building a road to Harrisburg of the same character. Commissioner Bigelow's attitude is an unanswerable argument in favor of the way that he stands ready for the way, illustrative of public sentiment for the way, that he stands ready for the state of Pennsylvania to continue the most magnificent highway ever planned to the capitol of the Keystone state. Mr. Bigelow declares whether he decides to build one or a double road to Harrisburg that the road will be completed in time for the great anniversary of the battle in 1913.

Harrisburg Club to Fight Bridge Tolls

HARRISBURG, PA., Dec. 11—At the regular meeting of the board of governors of the Motor Club of Harrisburg, held last Tuesday evening at the club's headquarters, Dauphin hotel, it was decided to use every reasonable effort to have tolls on the bridges across the Susquehanna river for all pleasure motor vehicles reduced to uniform charge of five cents for car and driver and one cent for each additional passenger. The present rates are ten cents for touring car and driver and five cents for runabouts and two cents for each additional passenger on all cars. Secretary J. Clyde Myton states that the board is very confident of accomplishing this desirable reform in the toll rate.

South of Anderson to the Keowee river the country continues level and from the Keowee river to the Georgia state line, which is the Tugaloo river, it is slightly rolling. Considerable grades are found, particularly in the latter portion of this stretch. The character of the road is perhaps not quite so high as it was back in the level stretches, but it is well up to the average good road of the South.

The following classification of the roads of South Carolina, as represented by the highway referred to, shows the attitude of the state toward progress. The 20 miles of macadam noted above occur in scattered stretches, particularly entering and leaving Spartanburg, Geenville and Anderson. The longest stretch is the one south of Spartanburg which extends about 7 miles.

The fair to poor roads are those near Gaffney, probably 6 miles of graded new road that makes hard going in wet weather, particularly if deeply rutted. There are also spots of a mile or more to be found at Blacksburg, Taylor, Piedmont and several of them during the final dozen miles north of the Georgia line where considerable work is needed. There are six or seven unbridged fords, none of which is important, but over which bridges and culverts would prove advantageous.

Convict Labor Used to Improve Roads

Convict labor is used exclusively in country road improvement in the state. There is, of course, much contract work to be found in the cities, but out in the country the sight of gangs of striped convicts at work on the roads is of frequent occurrence.

The state is particularly favored in its natural road material, and, as will be noted in the accompanying series of illustrations, it lends itself to the making and maintenance of fine roads.

A few years ago this whole road was just wide enough for the passage of cotton-laden teams. It was not bad even in those days, but its condition was due to nature quite as much as art.

Widening and standardizing the road from Glover to Blacksburg

There was no effort made to reduce grades, where such reduction would cost any considerable sum of money. To-day, this road is practically new from end to end. Where it follows its original lines it has been widened to 16 feet and crowned to shed water. Some effort to make ditches is also to be noted. While the grades in South Carolina never were really heavy, owing to the flatness of the country, there was room for some improvement in this respect. Since the first real movement began to better the road, fourteen cuts have been made that reduce the average grade to a small fraction of over 1 per cent. This has necessitated lowering the grades over a distance of 18 miles. There never was any great necessity for making fills.

The sand-clay packs easily and when it is dragged, after a shower or period of wet weather, it settles soon into a compact surface that becomes a fine, hard road in dry weather if allowed to remain undisturbed until it has had a chance to shed or absorb the water.

There is approximately 15 per cent. of sand in this surfacing material, and as both clay and sand separately and mixed can be found almost anywhere along the road in quantity the state is peculiarly fortunate in that respect.

South Carolina's Greatest Needs

What South Carolina needs more than anything else is some diversity in agriculture and a few real hotels. Undoubtedly there is much wealth developed in the state through cotton culture and manufacture, but there would be more inhabitants of good class if there were more different kinds of produce raised. There is a notable lack of good things to eat offered at the tables of the best hotels in the western part of the state at least. The reason for this lies in the fact that there is no effort of commercial size to raise garden truck and the various kinds of meat. The farmers do raise enough for domestic needs and probably live much better than travelers or tourists.

Practically all the table stuff of South Carolina, one of the garden spots of the whole earth, is imported, save at the particular season of the year when the farmers find they have an overplus of produce. This, of course, limits the table sharply at all other seasons and confines it to hog and hominy in many instances.

The hotel buildings are not as bad as the table, but to house such a party as the Glidden Tour they proved utterly inadequate. One of the witty newspapermen who accompanied the tour wired to his journal something like this after spending the night at one of the cities: "The hotel has no baths and nobody could eat the food, but the proprietor has an excellent singing voice."

Thus some good can be found in the direst situation if only one will try to discover it. This applies even to the South Carolina hotel.

Jeff Davis Highway

LOUISVILLE, KY., Dec. 11—Work on the Jefferson Davis Highway, the proposed 300-mile pike road in western Kentucky, which had its foundation in the convention held at Paducah several weeks ago, has begun in earnest. As soon as the civil engineers complete a survey of Livingston county they will work Caldwell, Crittenden, Lyon and Trigg counties. Owing to its already perfect grading, McCracken county will be the last on the list. Nothing is in the way to hinder the immediate building of the road and it is expected that the highway will be at least half completed within another year. Motorists throughout the western section of the state are deeply interested in the project and it is believed that an extension of the highway will be made later.

Another Toll Road Abandoned

BALTIMORE, MD., Dec. 11—Now that all tollgates within the city limits have been discontinued the commissioners of Baltimore county are following suit in their territory. The first gate in the county to go was that on the Charles Street avenue extension, which runs through one of the most fashionable suburban sections adjacent to the city. The gate was removed and the road made free through a deed transferring it to the Baltimore County Commissioners. The removal was a great surprise to the residents of that section for they had no previous notice that they were going to be so well treated. The toll road was owned by a subsidiary company of the United Railways and Electric Company, the directors of which, in view of the public sentiment favoring the abolition of toll roads, decided to deed the roadbed to the County Cimmissioners without cost to the county, but on condition that the company should have the right to lay tracks on the road and run cars over it should a line become necessary.

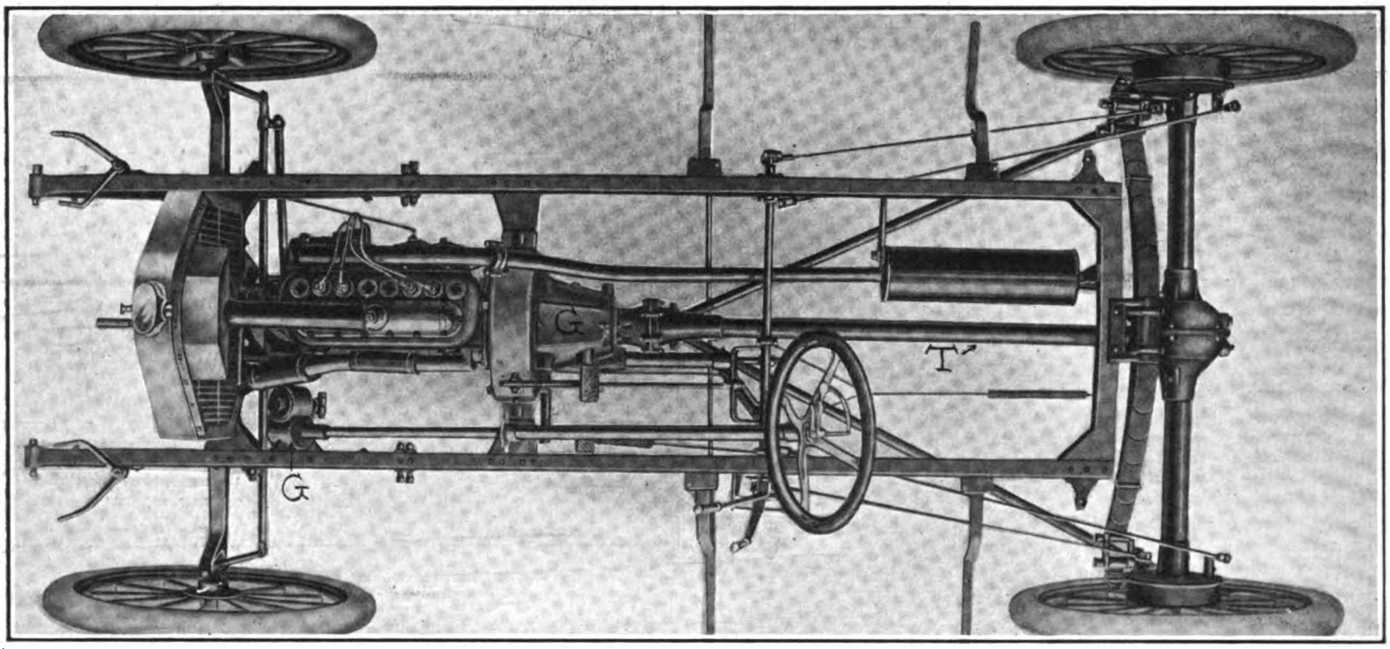


Fig. 1—Plan view of the 1912 Krit model "A" runabout chassis

Few Changes in the 1912 Krit Line

IN bringing forward its line of cars for the season of 1912, the Krit Motor Car Company, of Detroit, Mich., has made no radical departures from the models of previous years. The underslung model, which was introduced into the line last year, has been continued in order to meet the popular demand for this type of car. The underslung car is classified as model U, while the other two models are known as models A and K.

The motors of all three models of cars are of the same construction, being rated at 22.5 horsepower according to the A. L. A. M. formula and having a bore of 3¾ inches and a stroke of 4 inches. This gives a stroke-bore ratio of 1.065. The four cylinders are cast en bloc with the jackets integral, and, as may be seen from the plan view of the chassis shown in Fig. 1, the tops of the cylinders are faced off to allow of the manifold being bolted directly on them. The cylinder casting is connected to the crankcase by means of heavy holding-down bolts as shown in Fig. 2. The broad flange which forms a means of connection between the two castings makes for a tight connection through which the oil thrown from the crankcase will not readily leak.

The material of the pistons is gray iron. They are made by being first cast to a rough fit and then machined and ground to accurate size. They are annealed in the process of manufacture so that they are rendered less brittle and able to stand shock better. Each of the pistons is fitted with four rings, to be seen in Fig. 10, three of them being above the wristpin, while the fourth is located just below it. The wristpin, which is shown at P in the same illustration, is driven into the aperture which is located at the center of the length of the piston and is fastened in place by means of the two set screws shown at S. The upper end of the connecting rod is inserted first and the wristpin passed through it. The set screws are then put into their correct positions and screwed firmly home. The lower end of the connecting rod is fitted with a cap, C, which is placed over the crank-bearing and clamped into place by means of the two cap bolts B. The oil grooves in the connecting-rod cap are shown in the illustration. The pistons and rings are lapped into the cylinder so that a tight and efficient fit is secured. The pistons, connecting rods and wristpins of any cylinder weigh the same as any other set, so that one of the factors toward static engine balance is thus secured. Wristpins are hollow and case-hardened, with an oil hole in the center.

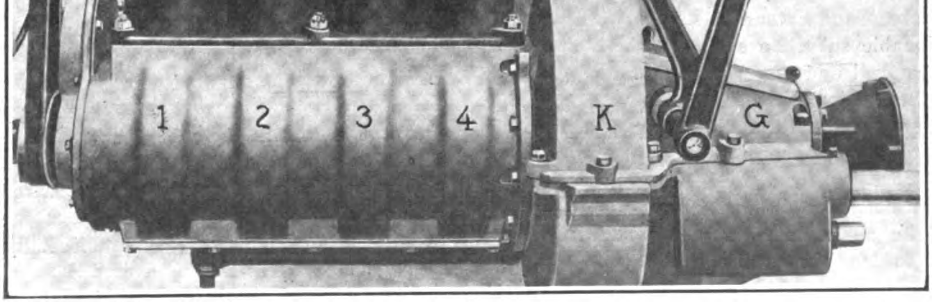

Fig. 2—Left side of motor, showing broad flange for connecting cylinder casting to crankcase

The crankshafts of all the Krit motors are carried upon two exceptionally large annular ball-bearings, the balls of which are ¾-inch in diameter and are carried in the cages indicated at 1 and 2 in Fig. 10. The shaft itself is a drop forging of special alloy steel. A feature in the construction of the crankshaft is the large connecting-rod bearings which are designed for durability and for the avoidance of the necessity of frequent adjustment.

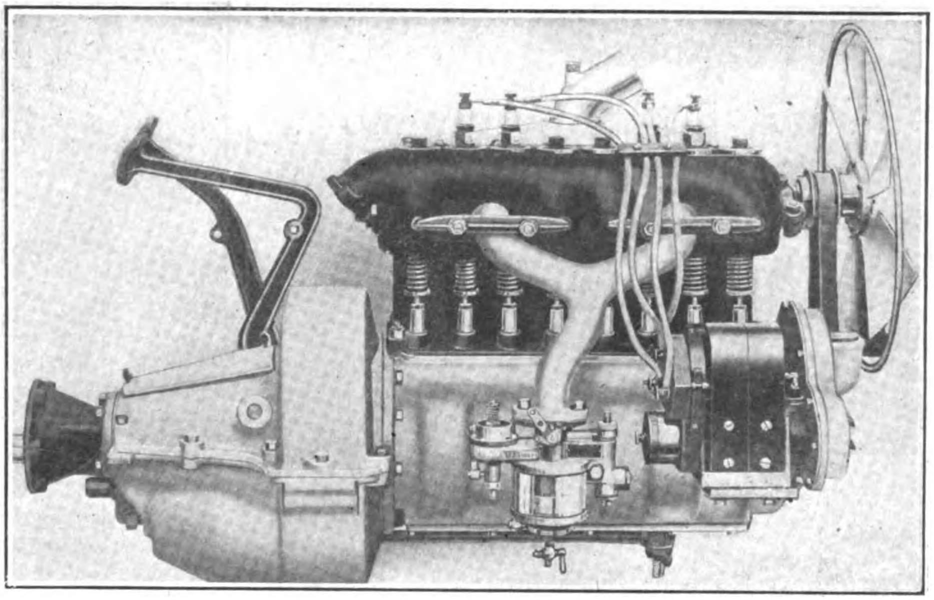

Fig. 3—Valve side of motor, showing small amount of exposed mechanism

The valves are completely interchangeable, both the exhaust and inlet valves having the same dimensions throughout and being placed upon the same side of the motor. They are hence driven from the same camshaft and by a single set of cams. The material from which the valves are constructed is nickel steel; they are made thick so that warping difficulties due to the high temperature to which they are subjected have been eliminated to the greatest possible extent. The valve side of the motor is shown in Fig. 3, and from this a fair idea of the amount of valve mechanism exposed may be readily secured. The adjusting device on the tappet-rods is readily accessible as may be seen from the illustration, being located just below the valve springs, which are also exposed. The valve push rods are ground to size and mounted in the cylinder casting, while the valves themselves are ground in the usual manner to their seats.

The camshaft is an integral forging, the cams being one with the shaft. It is carried upon plain bearings which are lined with bearing metal. The camshaft and cams are hardened together and ground to size. The camshaft is driven through a set of half-time gears which are located in a casing at the front end of the motor. The casing is shown in Fig. 3. It is oil-tight but may be readily disassembled by the removal of the small bolts which hold it together. The gears are three in number and are of the spiral type. The breather pipe is an integral part of the timing gear case. The magneto as well as the camshaft is driven by means of this train of gears.

The motor is cooled by water which is circulated by the thermo-syphon system. A free water circulation is maintained owing to the monobloc jacket casting, which reduces the number of partitions around which the water must pass to a minimum, and hence aids greatly in the rapidity of circulation. The latter feature is of great necessity in a motor using the thermo-syphon system, and hence has been given special attention. The water piping is of aluminum and is 2 inches in diameter. The connection between the piping and the radiator is of rubber hose, so that all vibrational strains are taken from the metal piping. The radiator is of the vertical tube type, of large size, and is cooled by means of an aluminum fan which runs upon ball-bearings and is driven by means of a leather belt operated directly from the crankshaft. The belt is 1 inch in width and is adjustable for tension.

The carbureter is of Stromberg make and is located on the right side of the motor. This carbureter is of the concentric float type, having the float chamber and mixing chamber in one body. The carbureter is controlled in the usual manner by means of the lever on the steering wheel spider, which, by means of bell crank levers, operates the butterfly throttle-valve in the carbureter.

Ignition is effected by the Bosch high-tension magneto. No battery or coil is used in connection with the ignition system, the magneto sufficing for all purposes.

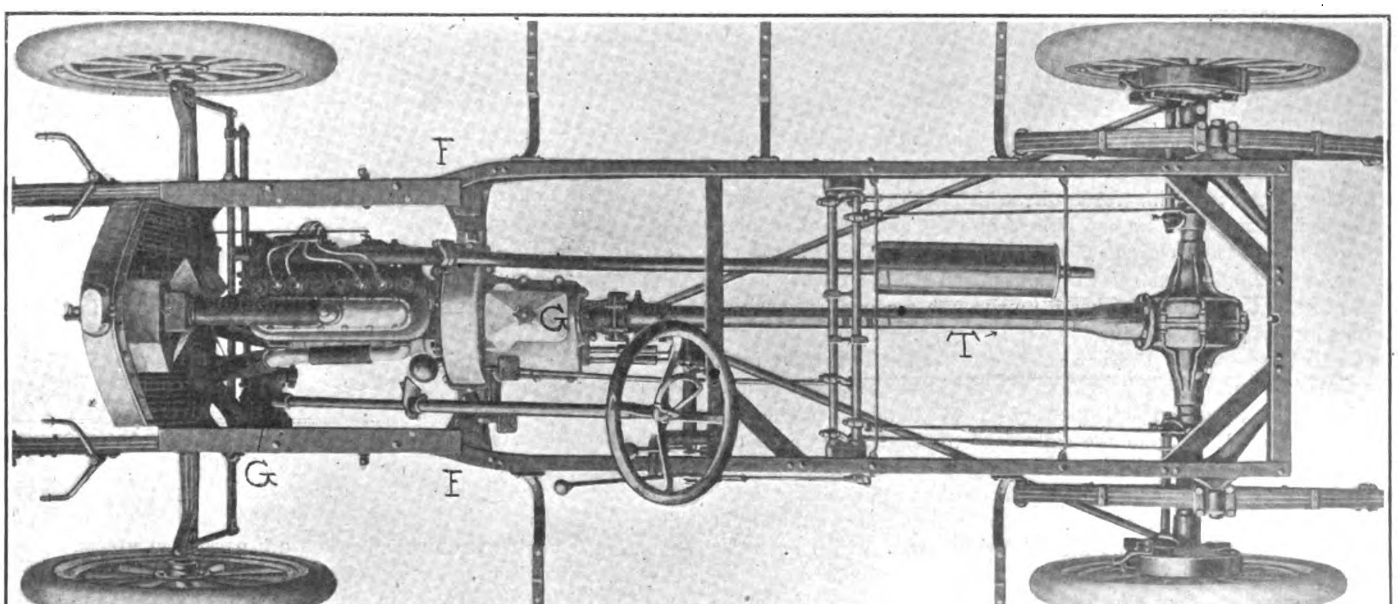

Fig. 4—The Krit touring car chassis, showing its simplicity and compact arrangement

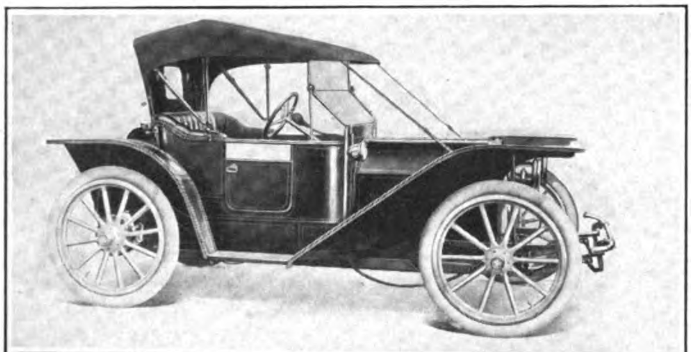

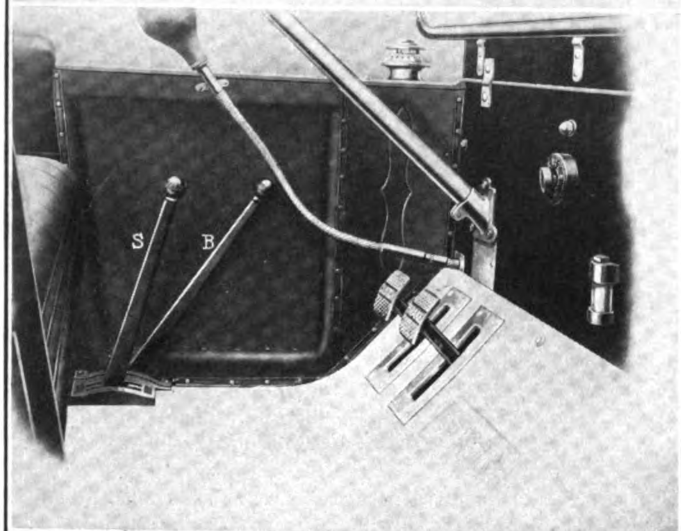

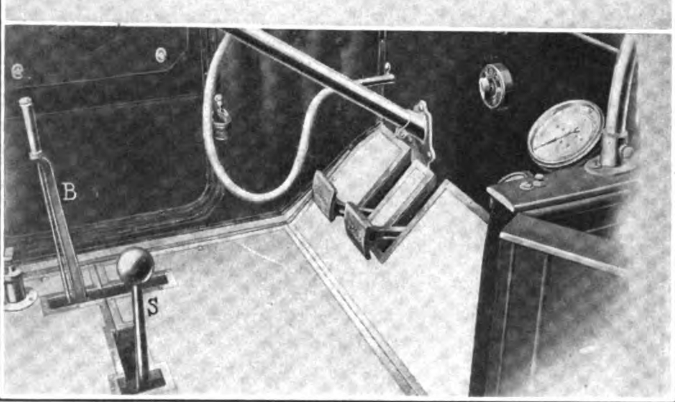

Fig. 5—The Krit underslung roadster ready for the road
Fig. 6—Roadster dash and control levers
Fig. 7—Gearshift lever is in center on touring car

The motor is lubricated by means of the splash system. The oil is carried in the reservoir which forms an integral part of the crankcase casting. This reservoir, which is located in the bottom of the casting, has a capacity of about 5 quarts and supplies the oil for the lubrication of all moving parts of the motor. A pump, which is driven off the camshaft, lifts the oil from the reservoir in the base and takes it up through a copper lead which passes into a sight-feed located on the dash. All the oil in the lubricating system of the car must go through this sight-feed, so that the operator has at all times a ready means of being able to judge the condition and quantity of oil contained in the system. The oil flows from the sight-feed to the crankcase of the motor. The crankcase is divided into a number of troughs, into which the oil is led. The connecting-rods, as they dip in their stroke, pass through the pools of oil which are contained in these troughs. This churns the oil into a spray, which pervades the entire crankcase and is thrown up into the cylinders.

The pistons on their downward path pick up the oil from the side of the wall and lift it up higher in the cylinders until they are thoroughly lubricated. The purpose of the lower of the set

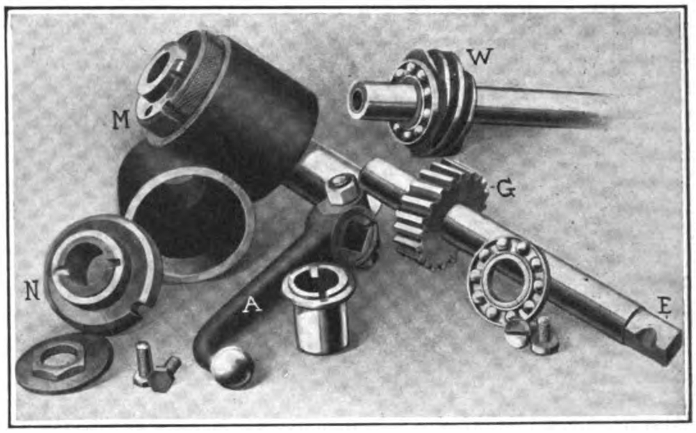

Fig. 8—Parts of Krit steering mechanism. Note ball-bearing thrust

of four piston rings is to eliminate any superfluity of oil and to keep it out of the combustion chamber. The level of the oil in the splash-troughs is kept constant by the supply which passes through the sight-feed. As the oil which is thrown about by the connecting-rods is continually draining back toward the troughs there will be an over-supply of oil in the upper part of the crankcase. This over-supply is taken care of by means of the overflow holes which are placed at the correct level. The oil which passes through these overflow holes passes back into the reservoir in the lower part of the crankcase. Before being recirculated the oil is strained by passing through a wire gauze screen. Oil is supplied to the crankcase reservoir through the breather-pipe. A change has been made in the oiling system of the underslung model in that it is unnecessary to lift the hood, seats or floor in order to replenish the supply of oil in the crankcase. This is also true of the gasoline and water supplies. An oil-pump on the floor of the car takes the oil from the reserve tank and places it in the crankcase. This operation may be made while the car is running.

The housing for the flywheel, clutch and gearset is illustrated in Fig. 9. This is an aluminum casting and is bolted to the aluminum crankcase in the manner shown in Fig. 3. A view of the clutch, which is of the multiple disc type, may be seen in Fig. 9. The discs are shown at C. The gearset shaft is a continuation of the clutch shaft, which is unbroken by a universal joint at this point and is supported by the ball bearings shown at B. The change-speed shaft is located in the lower part of the gearset housing, and is also carried upon annular ball bearings. The entire mechanism runs in oil which is contained in the gearset housing. That the supply of oil may be readily drawn off the gearset and fresh oil provided, there are drain-cocks fitted in the lower part of the housing. The manner of attaching the housing to the frame is shown in Fig. 4 at E. The change speed gear is of the selective sliding type, giving two speeds forward and one reverse. The reverse pinion rests idle while the car is moving forward. The material from which the gears are cut is of special steel. The change-speed gear operates along four keys cut integrally with the shaft. The material of the housing is aluminum. The hand-hole cover G is readily removable by simply turning the hand screw shown in Fig. 10, thus permitting of easy inspection of the change-speed mechanism.

The drive is taken up by the propeller shaft through an inclosed universal joint. The housing, which is connected to the torque tube T, takes all the strain from the universal joint. This is the same construction that is used at the rear of the propeller shaft, where a universal joint is also fitted for the purpose of providing protection against the changes of alignment which occur, due to different loads in the car, and also to the road shocks encountered. Both the universal joints are packed in grease to insure silence and an ample supply of lubricant at all times, as well as to provide against noise in the gears.

Through the rear universal joint the drive is transmitted to the differential, which is of the bevel type. The short differential

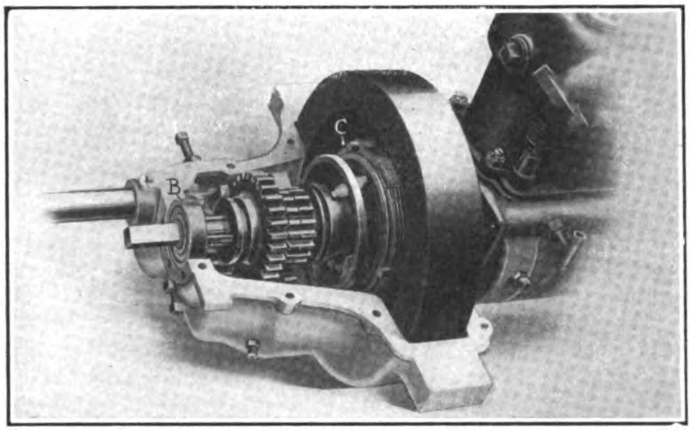

Fig. 9—Showing the simplicity of the clutch and transmission

shaft is carried on annular ball bearings and terminates in the usual star pinion which engages the bevel gear operating the differential wheels. From these wheels the power is transmitted to the semi-floating rear axle, which is carried upon ball and roller bearings.

The service brakes are of the internal expanding type on the models A and U, but on the model K they are contracting. The brakes are located on the rear wheel hubs and operate upon drums which are 9 inches in diameter. The emergency brakes on all the models are of the expanding type and are faced with non-burning material. The service brakes are fitted with equalizers through which the pressure on the drums on either side of the car is made equal; they are controlled by means of a pedal which is operated from the driver's seat. The emergency brakes are operated according to the usual custom, by a lever located to the left of the driver's seat.

The frame is of channel section 4 inches deep for the greater part of the length. It is of straight construction in models A and U, while the model K cars are equipped with frames whose side members are of the same dimensions as in the other two models, but having a single drop. The front axle is a one-piece drop forging of vanadium steel having an I-beam section. The spindles are drop-forged and are also of vanadium steel.

The chassis is supported by semi-elliptic springs in front and in the rear on the models A and U by a single transverse emi-elliptic spring. The model K chassis is supported in the rear by two scroll elliptic springs. The material of which the springs are composed is vanadium steel.

The steering mechanism is of the worm and gear type. It is shown disassembled in Fig. 8. The thrust on the gear is taken by a ball thrust joint designed to eliminate jar on the arm of the operator. The worm is shown at W with the ball bearing in position. The gear G is fitted on the shaft E which carries the arm A, the whole fitting into a sleeve housing M and inclosed by the cover N. The housing is dust-proof and is packed in grease to promote silence and durability in this part of the mechanism. The steering wheel is of Circassian walnut and is 16 inches in diameter. The steering column is rakishly tilted at an angle of 33 degrees. The housing is shown bolted to the chassis frame at G, Figs. 1 and 4.

The wheels are 32 inches in diameter and are made from selected second-growth hickory stock. They have twelve spokes and rotate on ball and roller bearings. The tires used in connection with the wheels are 32 x 3 inches both front and rear. On the model U underslung the wheels are made extra large, being 36 inches in diameter and using 36 x 3 1-2-inch tires. The wheelbase of the model A is 96 inches, that of the model U 98 inches and of model K 106 inches. The road clearance is 10 1-4 inches on the underslung model and 11 inches on the other models.

The control mechanism is illustrated in Figs. 6 and 7, where S is the gear-shifting lever and B is the emergency brake lever. It will be noticed that the brake lever is on the left side of the driver's seat on all models. The gear-shift quadrant is different on the model K cars, where three forward speeds are given instead of two.

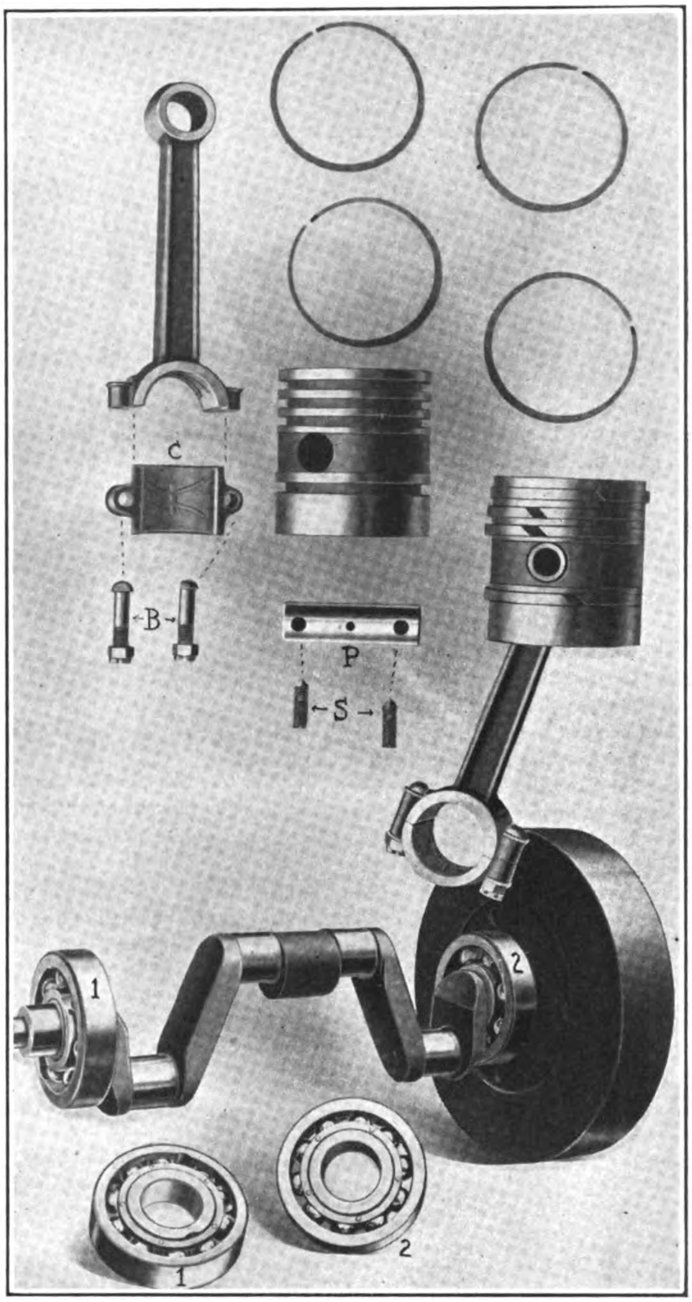

Fig. 10—Some of the Krit motor parts. Four rings are used, one below the wrist pin. The main bearings of the crankshaft are carried on two exceptionally large annular ball bearings

The equipment furnished with the cars includes three oil lamps, two gas lamps, generator, horn, tool kit, full set of tools, jack, pump, tire repair kit, top including side and corner curtains, windshield and demountable rims.

Odorless Blue Smoke—Experiments are reported in *Chemiker Zeitung* by Dr. F. Schwartz and Dr. H. Schlueter relating to a treatment with acetone of cylinder oil for automobile motors having for their object to remove the components which are least combustible and therefore most liable to cause a disagreeable odor in the exhaust gases. Trying the oil so refined competitively against the oil usually employed, and from which it had been produced, it was found that the new material produced clouds of smoke in case of excessive oiling, but the clouds were odorless. —From *Automobil-Betrieb*. November 1.

Transmission Ratio and Torque

By Forrest R. Jones

It is doubtless well understood in a general way that change-speed gears are used in the transmission system of an automobile in order to obtain, when the gears are set at one of the slower speeds, tractive effort at the road wheels sufficient to drive the car up a steep grade or along a heavy road, to obtain slow speed of travel in crowded streets or on a rough road, and to make the starting of the car certain without running the risk of stopping the motor. The latter applies especially when the clutch is one of those that have the very prevalent fault of taking hold suddenly so that the road wheels must either spin or the motor stop, in either case causing the car to start with a lurch, especially on an upgrade. The tractive effort of the road wheels is due to the rotary effort of the motor which is transmitted to the road wheels through the transmission system. Rotary effort is also known as torque, twisting effort and turning moment.

The rotary effort or torque delivered to the driving road wheels is greater than the rotary effort of the motor, in the usual forms of construction, probably in all forms. This does not mean that the power delivered to the road wheels is greater than that delivered by the crankshaft of the motor. The power received by the road wheels is always less than that delivered by the crankshaft of the motor, because some of the power is lost during transmission on account of the friction at the bearing surfaces which slide or roll over each other. If there were no frictional loss then the power received by the road wheels would be exactly the same in amount as that delivered by the crankshaft of the motor. A clear understanding of this and of the meaning of torque and analogous terms can be obtained by dealing first with some very simple cases leading up to the conditions which exist in automobile transmissions.

Fig. 1 represents a beam provided with three knife edges, A, B and C, such as is used for weighing scales of the beam type. The intermediate knife edge B rests on a support. Each of the other knife edges has a clevice hanging on it, so that weights may be suspended from them. The beam is made heavy at the short end so that it balances on the support when no weights are suspended from the clevices. If a weight is hung on the device at either end of the beam it has a tendency to draw the corresponding end of the beam downward and thus swing the beam around the intermediate knife edge B. The amount of this tendency is expressed by the product obtained by multiplying the weight by the horizontal distance between the intermediate knife edge B and the knife edge on which the weight is hung. This distance is called the lever arm of the weight. If a 200-pound weight is hung from the clevice on A, and its lever arm is 6 inches, as shown, then the amount of the tendency to swing the beam downward is: 200 pounds × 6 inches = 1,200 inch-pounds.

The beam can be prevented from swinging by hanging a suitable weight on the clevice at the short end of the beam. The amount of this weight must be such that when multiplied by its lever arm the product will be 1,200 inch-pounds, as before. The lever arm at the short end of the beam is 3 inches. The required weight is therefore 1,200 ÷ 3 = 400 pounds.

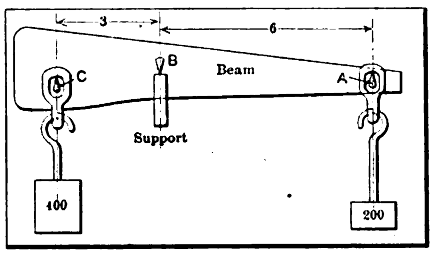

Fig. 1—Conditions of equipoise on lever

Fig. 2 is the end view of two drums and a shaft, all rigidly fastened together and supported by bearings in which the shaft is free to rotate. Each of the drums has a weight suspended by a rope which is wrapped around the drum and fastened at the end to the drum. For convenience it will be assumed that the drums are grooved to a depth such that the tops of the grooves are even with the center lines of the ropes.

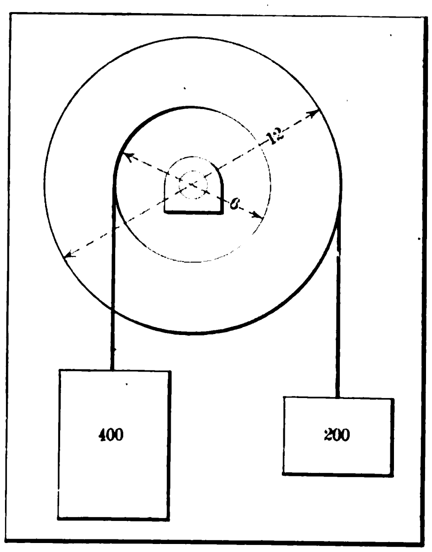

Fig. 2—Balanced weights on shaft and two drums

By this assumption, the radius of the drum is equal to the distance from the center line of the rope to the center line of the shaft. The radius of the drum is therefore equal to the lever arm of the weight that is suspended from the rope that is wound on the drum. The same apparatus is shown in a different manner in Fig. 3. These illustrations are both shown in order to make the construction of the device entirely clear. The weights and their corresponding lever arms are the same in value as in Fig. 1. Each weight has a tendency to rotate the drums and shaft in the direction that will unwind the corresponding rope from its drum. This rotative effort is 1,200 inch-pounds for each weight, obtained as before by multiplying together the weight and its lever arm. The shaft connecting the two drums is subjected to a torque of the same amount, 1,200 inch-pounds, since the rotative effort is transmitted through it from one drum to the other. Only the portion of the shaft between the drums is subjected to this torque, however.

If the drums and shaft are rotated, then the 200-pound weight will move twice as fast as the 400-pound one, since the drum on which its rope is wrapped has twice the diameter of the other drum. If the 200-pound weight descends 50 feet the 400 pounds are lifted 25 feet in consequence. The amount of mechanical energy expended by the lighter weight while descending through the 50 feet is expressed by the product obtained by multiplying the weight by the distance through which it moves, as follows: 200 pounds × 50 feet = 10,000 foot-pounds.

The amount of work done upon the 400-pound weight to lift it 25 feet, found in the same manner, is: 400 pounds × 25 feet = 10,000 foot-pounds.

During one revolution of the drums the 200-pound weight moves through a distance equal to the circumference of the drum on which its rope is wrapped. The drum for this weight has a diameter of 12 inches = 1 foot; the corresponding circumference is 3.1416 feet. The mechanical energy expended by the descending 200-pound weight during one revolution of the drum is therefore 200 × 3.1416 = 628.32 foot-pounds.

The amount of work done upon the 400-pound weight to lift it through the distance corresponding to one revolution of its drum, whose circumference is 1.5708 feet, is 400 × 1.5708 = 628.32 foot-pounds, which is of the same amount as the energy expended by the descending lighter weight during the same movement of the mechanism.

If there were no frictional resistance to the movement of the mechanism, then the mechanical energy expended by one of the weights while descending would be just sufficient to lift the other. On account of the frictional resistance to movement which is always present, the mechanical work accomplished is always less than the mechanical energy expended to accomplish it. For convenience, however, it is customary to assume that there are no frictional losses. This assumption is made in order to obtain a method by which the forces exerted to rotate the parts or to resist rotation can be readily computed. An allowance is then made for the frictional losses in accordance with experience or judgment. This method of neglecting frictional losses will be used still further in relation to the different forms of transmissions that will be discussed.

Two gear wheels on parallel shafts with the teeth of the gears intermeshing with each other are shown in Fig. 4. Each of the shafts also carries a drum that is rigidly connected to the corresponding gear wheel. Both of the drums are 8 inches in diameter. One of the gear wheels has forty-eight teeth and the other ninety-six teeth. The forty-eight-tooth gear must make two revolutions to rotate the ninety-six-tooth one through one revolution. This is because the larger gear has twice as many teeth as the smaller one. Since the teeth of the two gears engage each other, a rotative movement of one of the gears corresponding to one tooth plus one tooth space must be accompanied by a movement of one tooth and one tooth space of the other gear. The gears rotate in opposite directions.

Each drum has a weight suspended from it in the same manner as has been used before. When the gears are rotating the 300-pound weight on the drum of the forty-eight-tooth gear moves twice as fast as the 600-pound weight on the drum of the ninety-six-tooth gear, both drums being of the same diameter as has been stated. The distance passed through by the 300-pound weight during any movement of the mechanism is twice as great as that passed through by the 600-pound weight. If the 300-pound weight descends 20 feet the

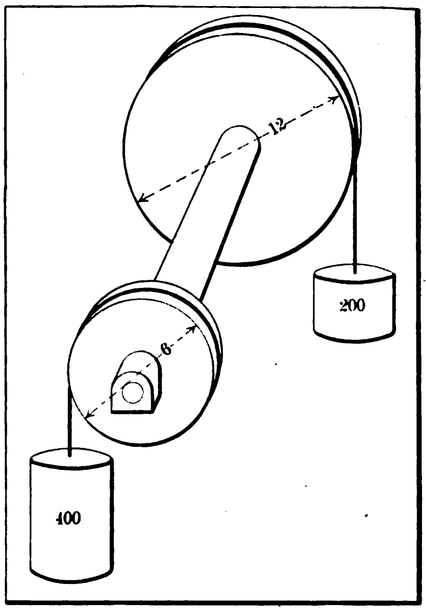

Fig. 3—Perspective view of weighted drum set

the energy given up by it is $300 \times 20 =$ 6,000 foot-pounds. During this movement the 600-pound weight is lifted 10 feet, which requires work done upon it to the amount of $600 \times 10 = 6{,}000$ foot-pounds. The energy expended and the work done are equal in amount in accordance with the assumption that there is no frictional loss.

The torque in the shaft of the smaller gear is equal to its suspended weight multiplied by the radius of the corresponding drum. Its numerical value is 300 pounds $\times$ 4 inches $=$ 1,200 inch-pounds.

The torque acting on the shaft with the larger gear is determined in the same manner and is 600 pounds $\times$ 4 inches $=$ 2,400 inch-pounds.

The rotative speeds of the two shafts are inversely proportional to the numbers of teeth in the gears attached to them.

The torques acting on the shafts are directly proportional to the numbers of teeth in the corresponding gear wheels.

The torques are inversely proportional to the rotative speeds.

When the rotative speed of one of the shafts is known that of the other can be found as follows:

Rule 1—When two gears intermesh with each other the rotative speed of the second can be found by dividing the number of teeth in the first by the number of teeth in the second, then multiplying the quotient thus obtained by the speed of the first. Either gear of the pair can be considered as the first.

The rule is otherwise expressed by the following formula, in which one of the gears is called A and the other is called B.

$$\text{Rotative speed of gear B} = \frac{\text{Number of teeth in A}}{\text{Number of teeth in B}} \times \text{speed of A} \quad (1)$$

When the torque acting on the shaft upon which one of the gears is mounted is known, the torque acting on the other shaft can be determined by the following rule, in which it is assumed that there is no frictional loss.

Rule 2—When two shafts are connected together by two intermeshing gears, the torque acting on the second shaft is found by dividing the number of teeth in the second gear by the number of teeth in the first gear, then multiplying the quotient by the torque acting on the first shaft.

The formula corresponding to rule 2, designating one of the shafts and its attached gear as A, and the other shaft and its attached gear as B, is

$$\text{Torque for shaft B} = \frac{\text{Number of teeth in gear B}}{\text{Number of teeth in gear A}} \text{Torque acting on shaft A} \quad (2)$$

Fig. 5 is similar in its nature to the last preceding figure. One of the intermeshing gears has forty-eight teeth and the other 120 teeth. The smaller gear and its shaft are designated as A and the larger gear and its shaft as B.

If the gear A is rotated at the rate of 100 revolutions per minute, then in accordance with both rule 1 and formula 1,

$$\text{Rotative speed of gear B} = \frac{48}{120} \times 100 =$$

40 revolutions per minute.

The torque in shaft A, due to the 300 pounds suspension from the 8-inch diam-

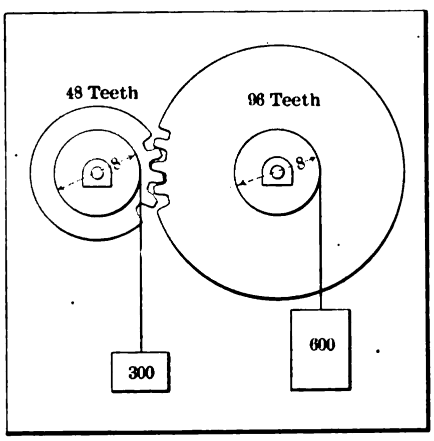

Fig. 4—Torque balanced on half-time gearset

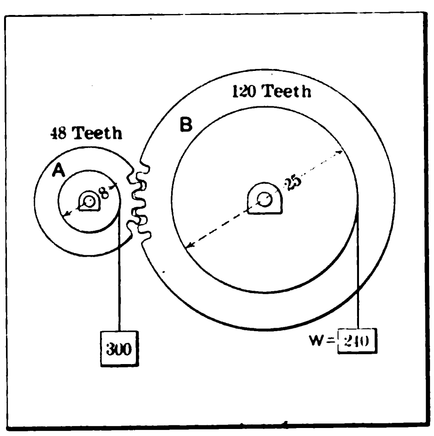

Fig. 5—Balanced torques on 2:5 reduction gear

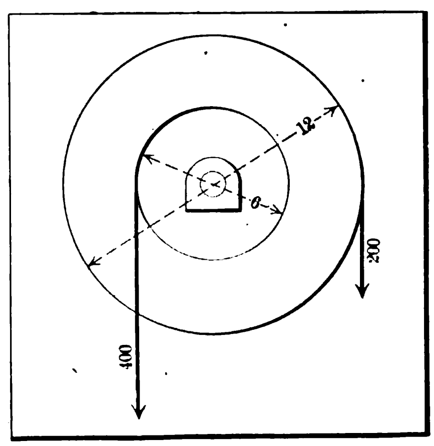

Fig. 6—Vectors indicating loads in diagrams

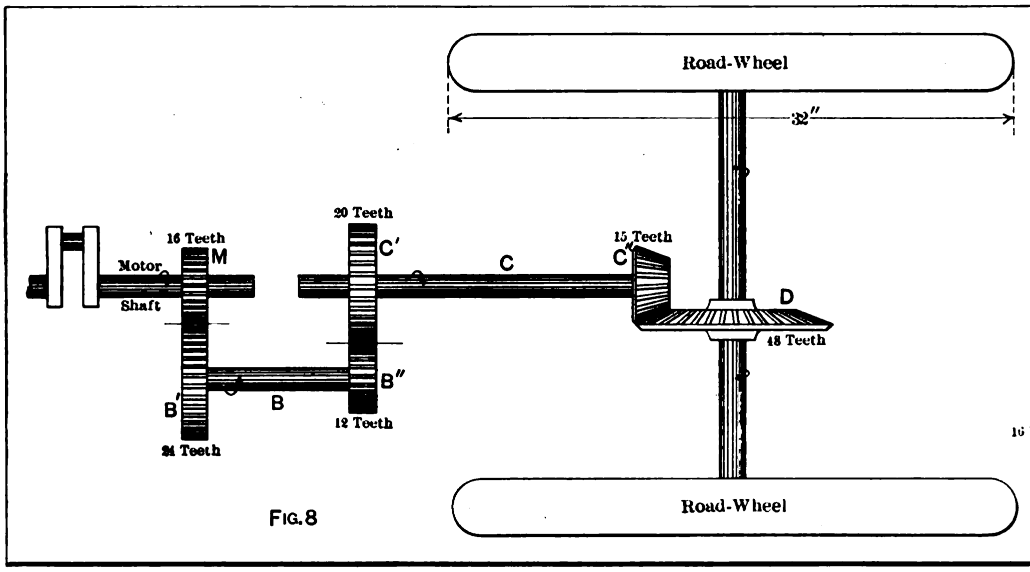

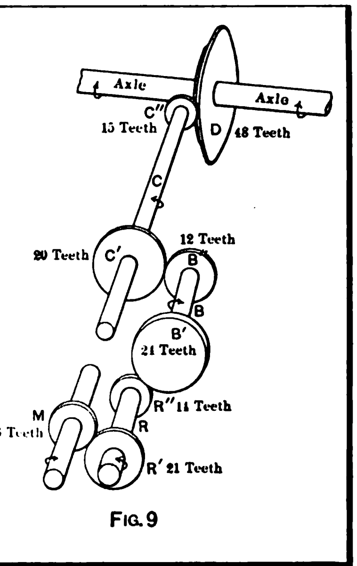

Fig. 8—Power transmission through change-speed gears. Fig. 9—Transmission gearset including reverse gear

eter drum, is $300 \times 4 = 1{,}200$ inch-pounds. The corresponding torque in shaft B, in accordance with rule 2 and formula 2, is:

$$\text{Torque for shaft B} = \frac{120}{48} \times 1{,}200 = 3{,}000$$

inch-pounds.

If this amount of torque is due to a weight W suspended from a drum 25 inches in diameter, as shown, then the amount of this weight can be found by dividing the 3,000 inch-pounds of torque by the lever arm of W, whose length is $25/2 = 12.5$ inches. Accordingly, $W = 3{,}000/12.5 = 240$ pounds.

Instead of showing the weights themselves, as in the preceding figures, each weight may be represented by a line. Thus, in Fig. 6, which is the same as Fig. 2, except for the substitution of heavy lines with arrow heads for the weights of the former figure, the heavy arrow-headed lines represent the rotative forces due to the weights. The arrow head indicates the direction in which the force acts on the body in connection with which it is considered. If the line is of such a length as to represent the amount of force according to some scale, as a scale of a certain number of pounds per inch of length, then it is called a vector. A convenient method, however, is to write alongside the line the amount of force which acts in the position indicated. This may be done either when the line is a vector or when it merely indicates the position and direction of the force.

The force represented by a line may be that due to any other source than a weight. The line may represent the pressure of a piston rod against its crankpin, the tractive effort of a wheel upon a roadway, the force of a spring, etc.

In Fig. 7, A is the crankshaft and C is the crankpin, which moves around in the smaller circle as the crankshaft rotates. The heavy arrow-headed line represents the amount and direction of the pressure of the connecting rod against the crankpin while the crank is in the position shown. This pressure or force tends to rotate the crankshaft. The rotative effort is found, as before, by multiplying the force by the length of its lever arm. The length of the lever arm is the shortest distance between the line of action of the force and the center of rotation of the part acted on by the force. In this case it is the distance, perpendicular to the line of action of the force, between the center of the crankshaft and the line of action of the force. The force is given in the figure as 600 pounds. Its lever arm is 3 inches for the position of the crank shown. The rotary effort is therefore $600 \times 3 = 1{,}800$ inch-pounds. The lever arm changes its length as the crankshaft rotates.

An eighteen-tooth gear is fastened to the crankshaft and meshes with a twenty-four-tooth gear on another shaft B, to which is attached a 32-inch drum or wheel whose rotation is resisted by a force T applied tangent to the 32-inch circle. The torque transmitted to the shaft B, due to the 1,800 inch-pounds of torque acting on shaft A, is

$$\text{Torque in shaft A} = \frac{24}{18} \times 1{,}800 = 2{,}400$$

inch-pounds.

The lever arm of the unknown force T is the radius of the 32-inch diameter wheel. Therefore, $T = 2{,}400/16 = 150$ pounds.

The force T may be considered as either the pull of a rope wound on the wheel or as the frictional resistance to slipping between the wheel and the floor or road upon which the wheel rests.

Fig. 8 represents the principle of the transmission system in an automobile with change-speed gears of the sliding type. The clutch and the differential gears are omitted in order to make the illustration as simple as possible so that no confusion may arise when referring to the different parts shown. The number of teeth given for one of the gears is 12 and 24 for another. In good practice more teeth than either of these numbers are used in a gear, but these small numbers have been selected in order to have a different number of teeth in each gear of the system so that each gear can be distinguished by the number of its teeth, and at the same time to keep the numerical part simple so that computations can be readily followed.

The gear wheel M receives power from the motor and transmits it to its intermeshing mate B'. From B' the power is transmitted through the shaft B to the gear B''. which in turn transmits it to its intermeshing mate C'. From C' the power is transmitted through the shaft C to the bevel pinion gear C'', which meshes with gear D. The power is transmitted from C'' to D and thence through the live axles to the road wheels. The latter rotate at the same speed as the gear D. The curved arrow on each shaft indicates the direction of rotation of the shaft and of the gears attached to it.

Considering each pair of intermeshing gears, one drives the other. Thus the gear M drives its intermeshing mate B'. All of the driving gears of the entire system as shown are M, B'', C'', and all of the driven gears are B', C', D.

The ratio of the speed of the motor crankshaft to that of the road wheels can be found in the following manner:

Rule 3—First determine which gear drives the other in each pair of intermeshing gears while the motor is supplying power. Multiply together the numbers of teeth in the driven gears to obtain a first product. Then multiply together the numbers of teeth in the driving gears for a second product. Divide the first product by the second product. The quotient is the ratio of the speed of the crankshaft to that of the road wheels.

By letting the letter which designates each gear stand for the number of teeth in the gear, the following formula can be used:

$$\frac{\text{Speed of road wheels}}{\text{Speed of crankshaft}} \quad \frac{B' \times C' \times D}{M \times B'' \times C''} \qquad (3)$$

As shown in the figure, $M = 16$, $B' = 24$, $B'' = 12$, $C' = 20$, $C'' = 15$, $D = 48$. By substituting these numbers in the last formula and solving it,

$$\frac{\text{Speed of crankshaft}}{\text{Speed of road-wheels}} = \frac{24 \times 20 \times 48}{16 \times 12 \times 15} = 8$$

This means that the crankshaft of the motor makes eight revolutions while the road-wheels make one.

Since the torques in different parts of a transmission system are inversely proportional to the rotative speeds of the parts when each of the parts is transmitting the same amount of power, the torque delivered to the axles of the road-wheels is eight times that in the crankshaft. It may be noted, however, that the torque delivered to the axles is divided into two equal parts for transmission through the axles, half of the torque going to drive one of the roadwheels and the other half going to the other road-wheel to drive it.

For each 100 inch-pounds of torque at the motor crankshaft there will be $8 \times 100 = 800$ inch-pounds of torque delivered to the axles, allowing nothing for friction loss. This is also the total amount of torque delivered to the road-wheels, or 400 inch-pounds to each road-wheel. The radius of the road-wheels is 16 inches. Therefore the tractive effort exerted by each road-wheel is

$$\frac{400}{16} = 25 \text{ pounds.}$$

When the side-shaft B and its gears are thrown out of operation, and the motor shaft connected to the shaft C for direct drive, then the bevel gears are the only ones in operation. The speed ratio of the crankshaft to the road-wheels is then $48/15 = 3.2$, and the torque delivered to the axles is 3.2 times that at the motor shaft under the same condition of driving. The tractive effort of each road-wheel for each 100 inch-pounds of torque at the crankshaft is then

$$\frac{100 \times 3.2}{2 \times 16} = 10 \text{ pounds.}$$

In Fig. 9 a pair of reversing gears, R' and R'', rigidly connected together by the shaft R, are shown in the transmission system. As before, the direction of rotation of each shaft and its gears is indicated by the curved arrow around the shaft. The number of teeth in $R' = 21$ and in $R'' = 14$. The velocity ratio of the crankshaft to that of the road-wheels is

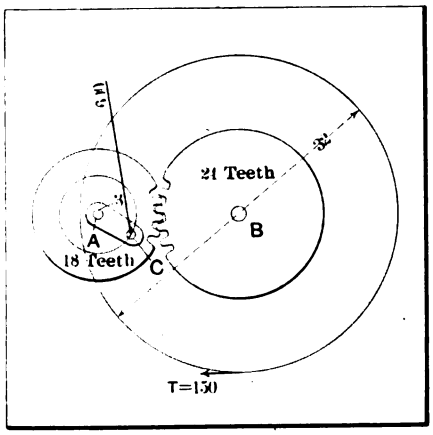

Fig. 7—Multiplying torque delivered at crankshaft

$$\frac{\text{Speed of crankshaft}}{\text{Speed of road-wheels}} = \frac{R' \times B' \times C' \times D}{M \times R'' \times B'' \times C''} = \frac{21 \times 24 \times 20 \times 48}{16 \times 14 \times 12 \times 15} = 12$$

This special ratio is 50 per cent. higher than that obtained for forward travel on slow speed, as has been computed. The torque in the axles and the tractive efforts of both of the road-wheels together are also greater in the same proportion. In the earlier automobiles advantage of this greater tractive effort was sometimes taken to run a car backward up a hill that it would not climb running forward on account of the motor not being powerful enough.

On account of frictional loss of power the tractional effort is of course smaller in each case than the amount obtained by the method that has been used. The actual tractive effort is obtained by deducting the friction loss from the values that have been determined. The amount of power lost in friction varies exceedingly in different transmission systems, and in any one system under different conditions of lubrication and adjustment of the bearings. In a well-constructed transmission system the power lost in friction between the motor and the road-wheels may be as little as 10 per cent. of the power of the motor. The friction loss will run as high as 40 per cent. or more in a poorly constructed or badly worn system while operating on one of the slower speeds.

Harking Back a Decade

FROM *The Motor Review,* December 12, 1901:

The Henry Ford Co., capital $60,000, has just been incorporated at Detroit. The company will manufacture an automobile designed by Henry Ford, a mechanical engineer. Mr. Ford will superintend the works.

The fourth annual exhibition of the automobile, the cycle and sports opened at the Grand Palace, Paris, December 10. Alcohol apparatus formed one of the most interesting exhibits. The show of motor implements for agriculture was impressive.

Under a ruling of the United States Circuit Court at Cleveland, the injunction granted against the Goodyear Tire & Rubber Co. on behalf of the Consolidated Rubber Tire Co. has been vacated. The suit was based upon alleged infringement of patents controlled by the Consolidated covering the use of wire passing through the core of the tire binding it to the wheel. The Goodyear company will now be allowed to make and sell tires again.

Four new rules have been added to the racing code by the Automobile Club of America. First, no automobile shall receive further attention and care by others than the driver and mechanic after having been placed in the starter's care. Second, in all races for record automobiles shall be classified by weight. Third, bicycles, tricycles and tandems shall not compete with four-wheelers. Fourth, during the running, only the driver shall have control of the steering power.

Mr. and Mrs. Robert Shaw, of Chicago, have sailed for Paris for a tour of southern France and Spain in an automobile. The Shaws intend to make a more extended tour next Spring.

Exports of automobiles and parts from New York last week totalled $3,800 in value.

The Century Motor Vehicle Company, of Syracuse, is about to install a new selling plan for its product. This consists in sending factory mechanics into a certain sales territory to demonstrate the performance of the cars. The company is not considering the establishment of more agencies this season because it wishes to test out its plan of demonstrating by the mechanics.

The recent race meeting held at Narragansett Park proved to be a big success in a financial way.

The Chicago Automobile Club has commenced its winter program of entertainments and lectures. The first meeting which was held last week was attended by more members than ever were present at a club function. The club has decided to cooperate with the local golf clubs so that its members may have the privileges of the country houses of the golf clubs in return for similar town privileges for the golfites.

A patent has just been issued to Walter Twitchell on an automatic starting device. This consists of a spring which winds up with a key before starting and when released revolves the crankshaft.

Digest of the Leading Foreign Papers

Guiding Thoughts as Voiced by Renault

THE opinions, with regard to the proper principles for automobile construction, entertained by Louis Renault, of France, the well-known manufacturer whose recent visit to American factories is well remembered, have lately been the object of considerable public attention which can be only in part accounted for by the commercial and technical success of the Renault manufacture. The fact that Renault's 1912 cars still bear the imprint of certain fundamental ideas which he conceived before the opening of this century and embodied in his product in opposition to the views then currently accepted, has fostered a high opinion of his intuitive insight, and the fact that he never graduated as an engineer but burst into actual manufacture on a small scale at the age of 19, together with his brother Marcel who was killed in the Paris-Madrid race of 1902, has added a certain glamour to his reputation as a designer endowed with a peculiar understanding of the essentials among a maze of mechanical possibilities.

In connection with his visit to the automobile show in Berlin last month Mr. Renault was interviewed by Dr. Ernst Valentin and the latter has rendered an account of the opinions which were expressed on that occasion; an account in which Dr. Valentin refrains from all criticism while prefacing it with a declaration of somewhat general dissent.

The account deals successively with the first basic principle for choosing among proposed innovations, valveless motors, repair facilities, clutches, spring suspension, metal and wood wheels, maximum and average efficiency of motors, motor lubrication and unit construction. Mr. Renault said, in substance:

"It is a great error to heed the fashions, as doing so cannot be reconciled with the necessity for having every innovation tried out for months or years by competent technical persons.

"My principle has always been the greatest simplicity consistent with greatest durability, and I therefore long ago rejected chain-drive, make-and-break ignition, water pumps and automatic regulation of the motor.

"It should be the automobile designer's aim to get along with the smallest possible number of parts in the automobile and in each part of the automobile.

"I have tried all innovations fully before rejecting them.

"As my views on valveless motors are especially desired, I will say that I have made very extensive experiments with sleeve-valve motors and have reached the conviction that it would be wrong to throw over our excellently proved-out poppet valve system as yet. It is true that the sleeve-valve motor by its noiselessness has contributed to advance the art of construction materially, compelling imitation of this feature, but it is false when the silence of the valveless motor is ascribed solely to the abandonment of the poppet valve. The latest types of poppet valve motors which are also justly designated as noiseless prove the correctness of this view.

"By the abandonment or improvement of the gearing used for driving the camshaft one of the main sources of noise has been removed. Noise can also be obviated by using an elastic coupling between the armature shaft of the magneto and the motor shaft, as for example by the insertion of rubber discs in the coupling. First and last, however—and this is what the valveless motors have taught us—the whole valve mechanism should be encased in the interior of the motor. When the spaces in which the valve-rods work are filled with grease, it is impossible to hear any noise from the valves. And now, since the designers very generally have adopted these improvements, I am of the opinion that the noiseless poppet valve motor is more practical than the sleeve-valve motor.

"I don't believe in building many things into one unit but in placing each organ which may have to be repaired or inspected distinctly and separately; so that, for instance, a chauffeur may be enabled to take the cylinders of his motor down, clean them and put them together again without going to a factory or to a repair shop. I don't think it is possible to do this with a valveless motor in the same simple manner as with the current design. With the latter you can dismount the cylinder together with the valves without changing anything in the adjustments, and the danger is obviated of getting something changed which you can not yourself readjust as it should be.

"Furthermore, I don't believe it possible to prevent particles of carbon from the lubricating oil lodging in the motor and causing either more rapid wear or a necessity for more frequent cleaning than in the case of the poppet valve motor.

"Just as I have stuck to shaft drive with universal joints, to direct drive and to several other features, uninfluenced by fashion, I feel myself unable to abandon the leather-faced cone clutch. Since 1899 I have used a cone whose apex would be found at about the middle of the transmission box. By this arrangement, which I still consider most practical, the crankshaft is completely relieved of pressures.

"While it may be true that the multiple disc clutch is less exposed to wear than the leather cone, I still ask: Which is better; a construction feature requiring no attention whatever for one to two years and then needing only a new leather facing, or a mechanism which demands frequent attention and lasts forever if it gets it? I prefer a construction with which the chauffeur, if possible, has nothing at all to do so long as the vehicle is in service.

"Since the demand for comfort, in addition to reliability and speed, became general, I have experimented a great deal with spring suspensions and have reached the conclusion that the usual flat leaf springs are altogether satisfactory. But under normal load the springs should be stretched out and not curved, as a stretched spring oscillates more slowly than a curved one and carries the body much more quietly. This is especially of importance for the front springs, because the use of stretched springs there means a minimum longitudinal motion of the front axle. With well designed leaf springs the use of shock absorbers and auxiliary springs is unnecessary.

"Though I was among the first, many years ago, to use wire-spoke wheels on my cars, I have not found them as good as wood wheels. The metal wheel is strong only if made by first-class specialists, and it cannot be repaired offhand. Moreover, the wire spokes are subjected to uncertain strains because they stretch and contract much at changes of temperature. The wood wheel is much more yielding and has a certain springiness in itself. Note also that the Paris cabs which formerly were usually equipped with wire wheels have uniformly gone back to wood wheels. The principal reason for this was the trouble experienced in keeping the wire spokes clean. When the vehicles were cleaned with a hose, water got onto the spoke nipples, and it could not, as in the case of wood wheels, simply be wiped off with a rag or waste. In other words, wire wheels demand more work by the chauffeur, which is against my principles.

"Coming back to the motor, I admit that the fuel efficiency of the slide-valve motor is excellent at the maximum of power development. But you cannot run any motor at its maximum without wearing it out much too fast. The average power output must lie far below the maximum, to have reserve power for emergencies as well as for durability. All told, I hold that at the present stage the most advantageous motor to have in one's car is the ordinary type of poppet-valve motor with the valves all on one side, all controlled from a single camshaft, the valves all encased and the camshaft driven by noiseless gears or a chain.

"With regard to the lubricating system, the generally adopted and much praised force-feed circulation of the oil is, in my opinion, wrong. In its circulation the oil is bound to carry along with it minute particles of carbon or detrition material from the cylinders and, however fine-meshed the oil filter is made through which the oil is forced to pass before being used again, it is not possible to avoid some deterioration of the lubricant. Force-feed oiling is also irregular; with a new motor and tight bearings a higher pressure is required to force the oil in between the bearing members than later. And in the case of the crankshaft, the amount of play in the bearings depends largely upon the temperature of the shaft. The extra cost of using oil only once in the motor is insignificant, because the oil used in a circulation system must be thrown away, while that used only once in the motor can be very properly used for the transmission box and the rear axle.

"The so-called unit or block construction, in which the motor and the transmission gear are housed together, I consider illogical, because it results in a construction unit which is too long and rigid for the flexible vehicle frame. It must be suspended at three points, and the load at these points becomes too strongly localized. Furthermore, I consider it advantageous to combine only such elements as never, or at least only at very rare intervals, will require to be taken apart; for which reason I, for example, have taken the distributer out of the magneto and placed it accessibly at the end of the camshaft."—From *Allgemeine Automobil-Zeitung*, Nov. 3.

Mass Production and Science—A substantial connection between the improvement and cheapening of automobiles and the length of the ether wave produced by a certain red light would scarcely suggest itself to the average mind. It is fully established, nevertheless. The mass production of automobiles, as well as of other complicated types of machinery, depends upon the ability of the manufacturer to turn out the component parts by automatic processes and of such superlative accuracy that the very composite product into which they enter may be assembled from them without any recourse to fitting, filing or trying. Parts intended to be alike must be absolutely interchangeable, and this means in many cases that their dimensions must not vary more than one ten-thousandth part of 1 inch; and even less in the case of scientific instruments themselves used for measuring purposes. But it happens that in industrial establishments there is no available standard for controlling the measurements in the first place. All vary more or less with temperature, and some are subject to certain small periodical changes from year to year or month to month, in some manner related to the changes in terrestrial magnetism. The possibility exists that little inaccuracies, almost infinitesimal though they be, may accumulate—one being added to another or even multiplied through an error in methods—until some day they enter into conjunction with some of the unavoidable errors, due to adjustments by human hands or the wear of tools, and cause a series of parts to be turned out which vary just enough from other parts, turned out previously, to interfere with that complete interchangeability which is indispensable and which in Germany has given the whole method its name, i. e. *das Austauschverfahren im Maschinenbau.*

The modern manufacturing methods referred to have been developed chiefly in connection with automobile manufacture in the United States and are now sweeping into other lines of industry and into other countries, mainly Germany. The need of an absolute standard of measurement which would be available in factories has been at once felt and is now being met in a practical manner. It is at this point that the absolute length of a light wave, as determined by pure science, steps in upon the industrial arena and contributes an important share to render it certain that the greatest cheapness in automobiles may be combined with the highest quality and accuracy; namely, by safeguarding the only methods of production by which such a combination may be effected.

The foundation for this advancement was laid when the renowned American physicist Albert A. Michelson, of Chicago, while working at the International Bureau of Weights and Measures at Sèvres near Paris, established as a fact, which has been accepted by science generally, that the wave length of the red cadmium light in dry air and at a temperature of 15 degrees centigrade (hydrogen scale) and a barometric pressure of 760 millimeters, equals exactly 1 meter divided by 1553164.13. This standard which can be reproduced in any suitable laboratory at any time and place has also been adopted as normal for all spectroscopic measurements by the International Union for Solar Research. The micro-measuring machines which work with the length of light waves as a basis for comparison make use of the phenomenon of light interference for measuring purposes and are therefore known as interferometers. They have already found an intensely practical application for determining the components of metallic alloys quantitatively by spectro-analysis. The firm Carl Zeiss, of Jena, Germany, has, for example, lately placed in the market an interferometer designed by Professor Haber for the examination of fluids and gases, and in which the light refraction of the fluid or gas is made the means for a very fine determination of the chemical composition, the method being apparently applicable to solutions in acid of small pieces of test metal.

An explanation with many illustrations of the physical laws which come under consideration in the construction of interferometers intended for the standardizing of linear measurements is given in a serial article on "Machine Building with Interchangeability of Parts" by Dr. Ingenieur R. Crain, appearing in the September, October and November issues of *Werkstattstechnik.*

Non-Ferrous Metal Exposition in London—A show which will be held in Agricultural Hall, Islington, London, May 6 to 18 next, will offer the first public opportunity for passing in review the different metal industries which have nothing to do with iron and steel. Considering the enormous field which has been opened up in this direction through recent scientific progress, it seems remarkable that no one has before contemplated a comprehensive exhibition under one roof of the numerous and varied industrial applications of this relatively new metallurgical knowledge. About fifty different metals are now actually known. The majority of them are still of mainly scientific interest; others are essentially commercial, such as copper, lead, tin, zinc, antimony, gold, silver, platinum. These are the true, the good metals; and their number is gradually increasing at the expense of that of the others. Only a short time ago, vanadium, cerium, radium, iridium, selenium, palladium and several others were chiefly known for their rarity and their uselessness, and now their industrial utilization is widespread. No doubt the exhibition will be widely attended and will be imitated in other countries.—From *La Métallurgie*, Nov. 1.

The Desirability of Having Safe Cylinder Lubrication and yet avoiding partial combustion of the lubricating oil, which leads to smoke and odor in the exhaust as well as to deposits of the unconsumed carbon from the oil, accounts largely for the better results with regard to fuel consumption and regularity in operation which accompany liberal provisions for cooling of the walls of the combustion chamber, though a hot motor in theory should operate most perfectly.

Letters Answered and Discussed

Good Practice

EDITOR THE AUTOMOBILE:

[2,949]—I am enclosing a sketch showing the method I use for holding a patch which is being cemented to an inner tube. A small board is placed above the patch and one below it, and the two are clamped together. Someone told me that this was not a good thing to do, as if the clamp was left on for some time it was likely to crease the rubber, causing the tube to crack. Your opinion as to this will be appreciated. C. F. KEMP.

New York City.

Your sketch has been reproduced in Fig. 1. This method of holding a repair patch is very common, and, as far as we know there is no objection to it. The clamp cannot ordinarily be screwed down hard enough by hand to have any serious results as far as creasing or cracking the casing is concerned.

Cylinder May Not Be Cracked

Editor THE AUTOMOBILE:

[2,950]—I hear that one of the cylinders in an old four-cylinder automobile that I recently bought is cracked and has been patched or filled in. I cannot find any trace of the crack, still one of the cylinders does not work all the time. Is there any way in which I can find out which one is cracked, and is there any way to repair it? Also what would be the result if the car is kept running with a cylinder in this condition? Information through THE AUTOMOBILE will be appreciated.

Worcester, Mass. G. N. W.

The probability is that you have no cracked cylinder, and that the cause of the misfiring in one of the cylinders is due to a fouled spark-plug or to defective wiring. However, there are several ways of testing for cylinder cracks, one of them being as follows: Jack up the rear wheels so that they are free to turn, and drive them by the motor, after having first applied the brakes as a load. Run the engine with the timer advanced. If there is a cylinder-leak gas bubbles should issue from it. A leak which is due to a very small imperceptible crack will sometimes not appear until the motor becomes well heated under a heavy load. If you are reasonably certain after cleaning the spark plugs and going over the ignition wiring that you have a cracked cylinder the best course to pursue would be to take down the cylinder (or cylinders, if they are not cast separately) and examine it closely along the wall. To our knowledge, cylinder walls which are cracked cannot be satisfactorily repaired, although cracked jacket walls may be restored by electric welding. Thus it is seen that a crack in the cylinder wall is a rather serious matter, especially when two or more cylinders are cast together.

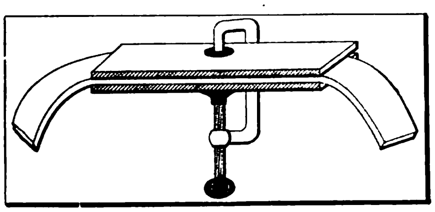

Fig. 1—How to keep a repair patch tight

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

If, after taking down the suspected cylinder, no crack is perceptible it would be as well to put it back as it is, as the loss of compression due to such an infinitesimal leak will not be appreciable.

There will be no ill effects other than the loss of compression and, hence, loss of power, from running an engine having a cracked cylinder wall. There is the possibility, however, of causing the crack to become larger by continued use, and it is not advisable to run a motor longer than necessary when it has a cylinder in this condition.

Piston Displacement

Editor THE AUTOMOBILE:

[2,951]—What is and how do you find the piston displacement of an automobile motor? Please answer through the columns of THE AUTOMOBILE. H. B.

Pittston, Pa.

The piston displacement is equal to the cross-sectional area of the inside of the cylinder multiplied by the length of the stroke. This is usually expressed in cubic inches. Referring to Fig. 2, take the diameter or bore d of the cylinder and use it in the formula $\frac{d^2 \times \pi}{4}$ to get the area. Next multiply this result by the length of the stroke l in inches to get the piston displacement. A is the upper limit of travel of the piston face and B the lower.

Wants Information on Ford

Editor THE AUTOMOBILE:

[2,952]—How many revolutions per minute is the maximum of which the Ford model S is capable?

(2) Can you tell me how the Ford model S is geared?

(3) Would it be worth the trouble to drill and tap the cylinders for another independent set of spark-plugs in order to get two simultaneous sparks at different points in the cylinders.

(4) Why is the clutch always placed between the engine and the gearset instead of between the gearset and the differential? OWNER.

St. Louis, Mo.

(1) Maximum revolutions, 1800 per minute.

(2) High speed, 37-11 to 1; low speed, 7 to 1; reverse, 11 to 1.

(3) It would not be worth the trouble.

(4) Because the flywheel offers a convenient housing for it and it would not be good practice to provide the additional weight which would be required by having another heavy housing. In allowing the engine to run free it would be necessary to allow the gears in the gearset to spin around. There are no advantages to be gained in placing it as you mention.

More Ford Points

Editor THE AUTOMOBILE:

[2,953]—(1) It has ben shown that electric headlights can be operated by the excess current generated by the Ford magneto,

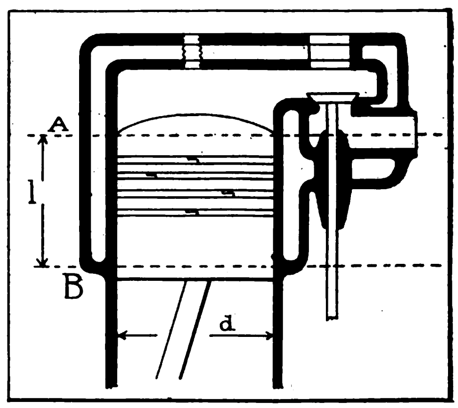

Fig. 2—Diagram illustrating meaning of piston displacement

but when I tried it either misfiring occurred or the motor stopped. Increased engine speed did not affect the misfiring. The lamps were 8-candlepower, 6-volt Tungsten filaments. Can you give me any suggestions as to the trouble?

(2) Are the Ford engine valves constructed so that adjustment of the stems is provided for?

(3) How can I increase the efficiency of the emergency brake, which is internal expanding and unlined? H. L. SHEPARD.

Rochester, N. Y.

(1) The Ford magneto is capable of lighting the headlights, as you state, but you have either wired it up improperly for this service or else you have a double ground in the circuit, caused by improper insulation or a wrong connection. Fig. 3 is a diagram which shows the way in which the headlights and magneto are usually connected on the Ford car. The headlights are wired in series. One wire is connected to a terminal of the magneto, and the other is grounded to the frame of the machine. If your headlights are already wired in series as shown the trouble may be due to the fact that you have connected the wrong terminal to the magneto, causing the double ground already mentioned. In this case the connections A and B should be reversed. It is a question whether or not the 8-candlepower lamps which you are using are the best for the purpose. At high engine speeds the electricity generated for lighting may be sufficient to burn out the filaments. On the other hand, if 10-candlepower lamps are used the current at low speeds may not be sufficient to light them.

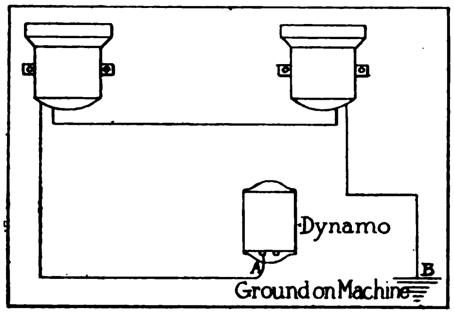

Fig. 3—Wiring diagram for electric headlights on Ford car

(2) There is no provision for adjustment of the valve stems of the Ford motor.

(3) As the expense is very small, the best way to increase the efficiency of emergency brakes is to replace the worn bronze shoes.

Why Experiment?

Editor THE AUTOMOBILE:

[2,954]—In your issue of October 19 you recommend the painting of tires with graphite when laying them up for the winter. Will Dixon's motor graphite answer the purpose? Do you not think that a liberal treatment of sulphur would be just as good? Would you recommend the storing of the tires in a cellar during the winter after either of the above treatments?

Earlsville, Ia. A SUBSCRIBER.

Any good graphite such as that which you mention will do. We have not heard of sulphur being used for the purpose, and hence cannot say as to the advisability of using it. Why experiment with something that has not been tried out and which is more expensive than graphite when the latter has proven satisfactory and is recommended by tire experts? While the use of sulphur might be even beneficial, automobile tires are rather costly articles on which to try the experiment, especially when there is so little to be gained by it.

If the cellar is not damp and has an even temperature around 50 degrees Fahrenheit no better place could be found in which to store the tires.

Prefers Broken Crankshaft

Editor THE AUTOMOBILE:

[2,955]—I have been surprised to notice that no exception has been taken to the statement that starting on the spark is detrimental to the motor.

As is well known, the explosive force of a gasoline mixture at atmospheric pressure is very low. That is why a compression of 50 to 60 pounds is used to give an engine power. Now an engine coming to a stop generally oscillates and finally stops with the pistons in a mid-stroke position, which means a low compression pressure. Furthermore a practical test by opening the petcocks after the engine has been standing for a few minutes will usually demonstrate that the amount of pressure remaining in the cylinders is a negligable quantity. This low compression, in connection with a half-condensed, slow burning mixture of gasoline vapor, makes it evident that the pressures and strains produced by starting on the spark must necessarily be much less than those incidental to the normal operation of the engine.

Is not a broken connecting rod or crankshaft cheaper than a broken arm?

Allegheny, Pa. MURRAY FAHNESTOCK.

Conceding the point that a broken crankshaft is in many respects less troublesome than a broken arm, but denying the necessity of either, we still maintain the inadvisability of starting on spark. The inertia of the stationary parts creates strains on the suddenly started mechanism which are far beyond those incurred in actual running or in starting either by hand or by automatic cranking.

Other Factors to Consider

Editor THE AUTOMOBILE:

[2,956]—Will you kindly tell a few other of your readers and myself where the discrepancy occurs in the ratings of the Vanderbilt Cup entries. For instance, the Mercedes has a bore of 5.1 inches, a stroke of 7.1 inches, a displacement of 579 cubic inches and 90 horsepower, while the Fiat has a 5-inch bore, a 7.48-inch stroke, a displacement of 588 cubic inches and 70 horsepower. Here are two cars, one having less bore and longer stroke than the other, yet with such vastly different horsepowers. Will you kindly explain?

ALFRED P. STEWART.

Charleroi, Pa.

Other factors besides the bore and stroke enter into the horsepower rating of a motor. The speed and compression pressure must also be taken into account. On page 1005 of our issue of December 7 you will find an explanation of this same point.

Direction of Cooling-water Flow

Editor THE AUTOMOBILE:

[2,957]—Will you kindly tell me the direction of flow of the cooling-water? Does it flow in at the top of the radiator and out the bottom, or vice versa? Also please tell me where in the cooling-water circuit the pump is placed?

Memphis, Tenn. A. L. CROSS.

The arrows in Fig. 4 show the direction of flow of water through the cooling system. The water enters the radiator at the top and flows out at the bottom. The pump is located as shown, between the manifold which admits the water to the jackets and the outlet pipe from the radiator.

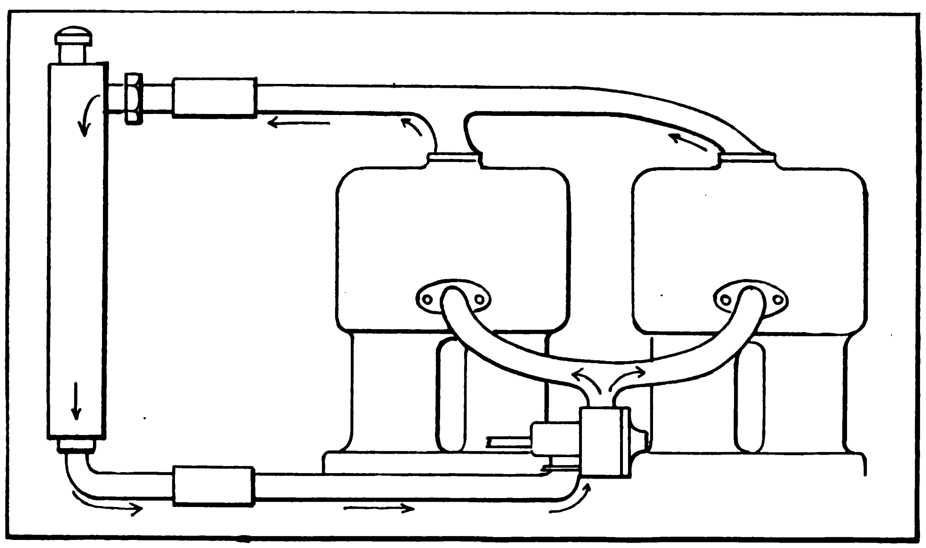

Fig. 4—Illustrating direction of water flow in cooling gasoline motor

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

REPAIR OF BROKEN SPRINGS—To the automobilist who has smooth, level roads on which to drive his car and to careful drivers, spring troubles are practically unknown. But in hilly localities and in places where the roads are rough mishaps to springs are not an uncommon occurrence. Springs are often broken by sudden jolts due to driving the car at a high rate of speed over rough roads where there are deep ruts and where the approaches to culverts are not properly graded. Accidents of this kind are usually due to carelessness in overloading the car and in driving, but, nevertheless, they do happen, and a few suggestions as to temporary spring repairs will not be amiss.

A break in the upper leaf is most common, the part nearest the hanger usually being bent upward. At A, Fig. 2, is shown a rather makeshift but effective spring repair for a break of this nature. If you are on the road when such a mishap occurs and have no spring clips or extra pieces of spring leaf at hand, this emergency repair will prove very satisfactory. The car should be first jacked up, the jack being placed at the end of the hanger. This will serve to relieve the tension on the under leaf and will bring the bent or broken upper leaf down somewhat. Next take a wrench and adjust its jaws so that they are far enough apart to go over the spring leaves at the point nearest the hanger. Then drive the wrench along the leaves toward the break, using a hammer and cold chisel (or other piece of steel) if necessary. This will serve to bring the bent upper leaf nearly down to its original position against the lower leaf. Next take a piece of hard wood about a foot long and shape it to the width of the spring leaves, as shown. Bind this block down firmly to the spring with whatever strong wire is at hand. It is a good plan to wind tightly over this wire a piece of clothes line rope, or other strong rope of about the same size, and then to wet the rope, causing it to contract, thus binding the joint very tightly. The wrench can now be removed, and the spring, though weak, will be found to be quite strongly repaired.

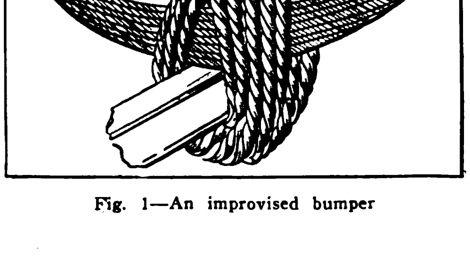

Fig. 1—An improvised bumper

The repair above outlined can be made use of when no spring clips or extra pieces of spring plates are to be had. When using a car on rough roads, it is well to include these things in the repair kit. A spring clip is shown at B, Fig. 2, and another and better way of repairing a broken spring leaf is seen at C. This repair is very satisfactory, and the car can be used with a spring fixed in this way until such time as the broken member can be conveniently replaced.

The piece of spring steel is first placed over the break, as shown, and the clips are then slipped on. Small blocks of hard wood are placed on the under side and the lower plates of the clips are bolted on over them. The particular advantage of this repair lies in the fact that the parts of the broken leaf can be readily brought down into their normal positions against the next lower leaf simply by tightening up on the nuts. For further strengthening, one or two more clips may be added, blocking them on the bottom in the same manner.

Of course, a repaired spring will not be as strong as the others, and for this reason it is likely to bump the frame whenever the car is jolted. If the car is not fitted with rubber bumpers or shock absorbers it is a good idea to place a block of wood at the spring center and bind it on with as many parallel turns of heavy rope as possible. This improvised form of bumper is shown by Fig. 1. This will serve to soften the impact, reducing the jarring of the frame and preventing it from becoming localized. When a garage or accessory station is reached this rope bumper should be replaced by a more suitable rubber one.

Any of the good forms of shock absorbers on the market materially reduce the chances for spring breaks, and wherever possible they should be included in the equipment of the car. Their cost is small in comparison with the trouble and expense incident to the repair of a broken spring. This is aside from the easier riding qualities which a full set of shock absorbers gives to the car.

HORSEPOWER RATINGS—Considerable confusion exists among automobilists and others as to the distinction between the various methods of determining the horsepower ratings of motors. As a matter of fact, there is a very large distinction between these methods, even though a great many persons do not appreciate it. Because a manufacturer states that the (A. L. A. M.) rating of his engine is a certain horsepower it does not necessarily follow that the actual horsepower which the motor will deliver on a brake test will correspond with his rating. Most manufacturers rate their motors according to the A. L. A. M standard. The formula which this body has set down states that the horsepower shall equal the product of the square of the cylinder diameter multiplied by the number of cylinders which the motor has, and this result divided by the constant 2.5. This latter figure is used because it is "based on the average view of the A. L. A. M. engineers as to a fair conservative rating for a four-cycle motor at one thousand feet per minute piston speed." Motors rated according to this standard are usually given a horsepower much below

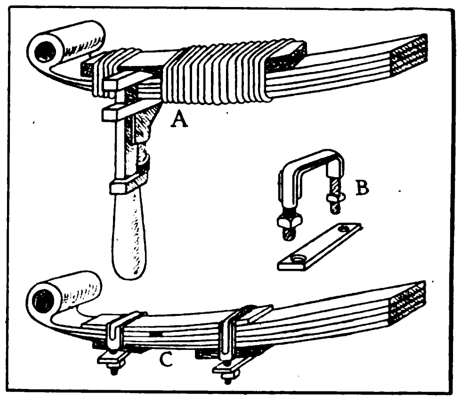

Fig. 2—Two good spring repairs and a form of spring clip

that which they are capable of developing under load. The formula does not take into account the compression pressure nor does it make use of the piston displacement, both of which factors are considered when the horsepower is determined by more accurate methods. The A. L. A. M. standard is of use for commercial purposes only in that it affords a means of comparing automobile motors as to power, but not as to the exact amount of this power. Thus, we say a certain car has 20 horsepower, according to A. L. A. M. rating, and another, 30 horsepower. The actual horsepowers may be around 30 and 40, respectively, but so far as the comparison of the two motors as to relative power goes, the more approximate rating answers the purpose equally as well as the other. Frequently we are asked to explain wherein the discrepancy lies between the engine ratings of various racing cars as set forth by the entry tables. Often two cars of nearly the same piston displacement are entered with widely different horsepowers, and this leads to a great deal of confusion in the minds of many. This horsepower difference is usually due to the variation in the design of the motors. It may also be due to the fact that either one of the cars or both have not been rated according to the A. L. A. M. standard, unless the only variables, the cylinder diameters, are far enough apart to make up for the difference. That is, if two motors have four cylinders each, in the A. L. A. M. formula $\frac{D^2N}{2.5}$ the only factor which can cause the variation is D^2, which is the square of the cylinder diameter. N represents the number of cylinders. Therefore, even though the piston displacements of the two may be about the same, in one case this may be made up by a long stroke and a small bore, while in the other the cylinder diameter may be large and the stroke short. Thus, the bores are not the same, consequently the ratings by this formula cannot be the same. A specific example will no doubt serve to illustrate this more clearly. Take, for instance, two four-cylinder motors, one having a bore of 5 inches and a stroke of 4 inches, and another having a bore of 4 inches and a 6 1-4-inch stroke. Each motor has a total piston displacement for the four cylinders of approximately 314 cubic inches, yet by substituting in the formula already given the motor with the 5-inch bore receives a rating of 40 horsepower, while the other figures out to be 25.6 horsepower. Of course, the piston speed is vastly different in the two cases, and it is unfair to use the constant 2.5, which is based on one thousand feet per minute piston speed, to compute both horsepowers. While the formula is very poor at best, it is seen to be absolutely worthless, unless the constant is changed to meet the specific conditions.

Another more nearly accurate and consistent way for getting at the power of a motor is by means of the indicated horsepower formula, which states that the latter is equal to the expression $\frac{(M.E.P.)\ lan}{33000}$.

In this formula l is the stroke in feet, a is the area of the piston face in square inches, n is the number of explosions per minute (usually considered as being half the number of revolutions per minute) and M. E. P. is the "mean effective pressure" acting within the cylinder throughout the cycle. The only difficulty arises in determining the last-named factor. It must be determined from an "indicator card" taken while the engine is running under load. For taking this card an indicator must be used. There are several types of these instruments on the market, one of them (Thompson) being shown in section by Fig. 3. The pointer traces on a paper attached to the drum, a diagram having pressure and volume co-ordinates in proportion to the actual pressures for the various volumes or positions of the piston throughout the entire cycle. This diagram is integrated—that is, its area is determined by planimeter or by computation, and, after taking into account the scale of the indicator spring, the mean effective pressure is determined by dividing the equivalent area by the length of the stroke.

For testing an automobile engine the indicator may be attached to the cylinder by screwing it into the priming cock hole. Cards need be taken on one cylinder only, and the result obtained by the above formula can then be multiplied by the number of cylinders to get the total power of the motor. It is sufficiently accurate to assume that each cylinder furnishes a proportionate part of the total developed.

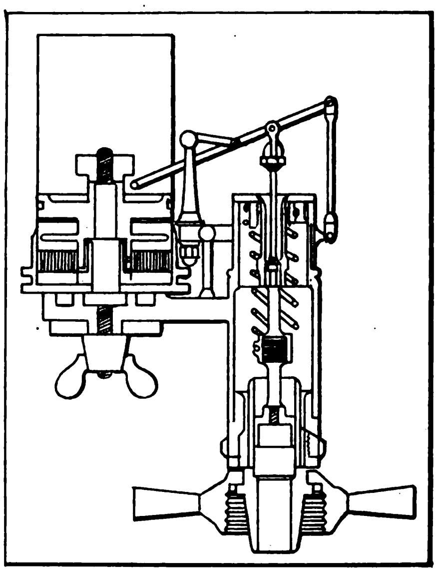

Fig. 3—A type of indicator to measure mean effective pressure within a cylinder

Perhaps the best method of getting at the horsepower output of a motor is by means of a Prony brake. The apparatus may be fitted up as shown by Fig. 4. The test can only be performed when the motor has been removed from the frame and mounted on some sort of testing block, such as is used in the garage. The Prony brake proper is shown by B. The strap D is put around the flywheel C, and its tension is regulated by means of the handwheel or other adjusting screw A. The end of the brake beam bears on the block E which, in turn, rests on the platform F of the scales. The motor is started running and the load applied by tightening up on the adjusting screw, the direction of rotation being as shown. To get the maximum brake horsepower of the motor the screw A is turned until the friction is barely overcome—that is, until the motor is running under such a load that a slight additional tightening of the strap D will stop it. When this adjustment is reached the friction is weighed by the platform scales, and the speed is noted with a tachometer or speed-counter. These readings should be taken, of course, when the motor is developing all the power of which it is capable.

Having obtained this data, the following formula is applied:

$$\text{Brake horsepower} = \frac{2\pi GAN}{33000}$$

The symbol π, of course, represents the constant 3.14, while G is the weight shown by the scales, A is the length of the brake arm in feet from the center of the flywheel to the center of the block E, and N is the number of revolutions per minute of the flywheel as obtained by means of the speed-counter.

When the test is properly carried out it gives a very near approach to the correct power output of a motor.

Another method of testing which is made use of chiefly by manufacturers is to direct-connect the motor under test to an electric generator, causing it to drive the generator and noting the electrical output in watts. The watt output can then be reduced to horsepower. This equivalent horsepower comes very near to the correct delivery of the motor, although it is slightly less than it should be unless the efficiency of the electric generator is taken into account.

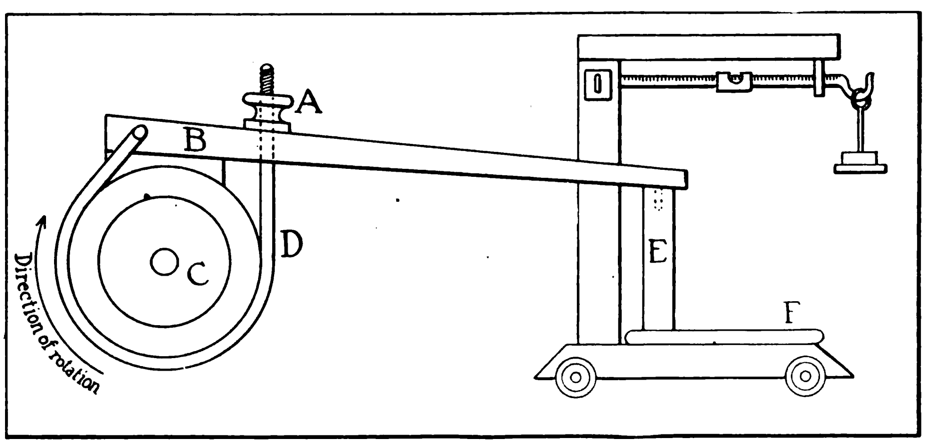

Fig. 4—Apparatus for making a brake test

My Best Automobile Repair

Some Quick Repairs Made in the Garage and on the Road

An Effective Lock

EDITOR THE AUTOMOBILE:

Several lock devices have been gotten out to prevent the automobile motor from being started by anyone except the person who is in possession of the key and they are all more or less practical. This provision is oftentimes very necessary when the car is allowed to stand for some time on a busy street with no one to watch it. Very often a car has been stolen at night by thieves who are able to start the motor by simply switching on the ignition current. I have never had any trouble of this kind, but I believe in the ounce of prevention and am sending you a sketch of the way in which I prevent the car from being used without my knowledge. Inside the battery box I have fastened a switch of the type used in electric light circuits. Fig. 1 shows a section through the box. The switch is seen fastened to the back of this box. If the box is of metal, a board can be fastened inside to its back and the switch then screwed on to this board. The switch is simply put in one of the wires leading from the battery, as shown. When the driver is to leave the car for some time the switch is turned off and the battery box locked.

It is safe to say that the thief or joyrider would give up the attempt to make away with the car when he found that he was unable to start it by switching on the current. Even if the battery box were not locked, he would hardly risk further investigation into the reasons for the motor's failure to run.

If the car is kept in a public garage, some such device as this gives the owner a feeling of satisfaction in knowing that there is no chance of his machine being taken out and possibly damaged by the garage employees. CAREFUL MOTORIST.

Philadelphia, Pa.

Protects Terminals

Editor THE AUTOMOBILE:

A useful hint to some of your readers may be gained from Fig. 2. On most cars all terminals are exposed, and hence there is liability of leakage from them to the adjoining metal parts. To prevent this, one way is to slip pieces of rubber tubing over them, as shown. This applies not only to the spark plug terminals, but to those on the magneto and battery as well. This tubing also serves to prevent the jarring loose of the connections. Nothing is more annoying when on the road than to have the motor stop for no apparent reason at all, and after going over half its parts to find no more serious a trouble than that a connection has jarred loose from its terminal. If the tubing does not readily slip over the terminals or plugs, it may usually be made to go on easier by wetting it slightly. B. L. BARNES.

New York City.

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Need of Safety Cranks

Editor THE AUTOMOBILE:

Just the other day I read in the paper of another broken arm as the result of trying to start a motor with the old-fashioned starting crank. There are on the market a number of safety cranking devices, which are made so as to be applicable to any car, yet the majority of automobilists still persist in using the old-style crank when one of the newer and safer ones could be added at small expense. Since having one of these put on my car I do not have the former guilty feeling when a friend cranks the motor for me. V. L. GASS.

Boston, Mass.

Product of a Fertile Brain

Editor THE AUTOMOBILE:

While this is not exactly to be classed as a repair, I think the suggestion might be of service to some other automobilist when he is out in the country sometime, and, after it starts to get dark, he discovers that the acetylene supply in his tank is very low. In fact, that is about what happened to me the other night. About dark I started out blissfully for a run in the country, and when I had gone perhaps 15 miles the headlights began to get dim, and finally went out. I was seriously considering abandoning the car for the night when I saw the lights of a country store shining dimly, perhaps 100 yards up the road. This gave me an idea, and I walked ahead to the emporium. There I bought two candles and begged a generous supply of string. Returning to the car, I tied a candle firmly to each gas jet and lit the candles. To my great joy, the light furnished by these old-fashioned articles when the reflectors were properly focused, was bright enough to enable me to proceed slowly, but none the less safely, to the nearest gas supply station. Now I carry a few candles as part of my car's equipment.

Yonkers, N. Y. J. C. HARRIS.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

A Long-Stroke Advocate

EDITOR THE AUTOMOBILE:

I have read with no little interest the articles on My Ideal Automobile and have decided to outline the car which I would like to own for 1912.

The motor should be of the four-cylinder, four-cycle, T-head type. The cylinders should be cast in pairs with a bore of 4 3-4 inches and a stroke of 7 1-2 inches. This should give a motor of about 60 brake horsepower. The electric current should come from a Bosch dual system, and the cooling should be by a honeycomb radiator and a gear-driven centrifugal pump. Oil should be supplied by a splash system and by a pump which would force the oil through a hollow crankshaft to the main bearings of the motor. The carbureter should be a G. & A. and a B. & L. Castor front axle should be included. The rear axle should be of the floating type. manufactured by Timken. The wheelbase should be about 130 to 134 inches, and the car should be equipped with 38-inch by 5-inch tires all around.

The steering gear should be similar to that used in the Marmon 32. The transmission should have four forward speeds and a reverse, with direct drive on the fourth speed, geared two to one. The springs should be semi-elliptic front and rear. The clutch should be a large cone with cork inserts.

I would have a roadster type of body, seating two, with large gasoline and oil tanks placed behind the seat.

I should think that a car such as I have outlined could be made to sell for about $2,750 or $3,000 and yet be built from the best of materials. GEORGE BRIGGS.

Sheffield, Mass.

Wants High-Powered Car

Editor THE AUTOMOBILE:

My ideal 1912 automobile would have a horsepower around 80, the engine bore would be 5 inches and the stroke 7 inches. There would be six cylinders, cast in pairs, with water cooling and T-heads. The ignition would be by Bosch dual system with governor control. Lubrication would be by force-feed to all bearings and by independent splash. There would be oil level cocks and drain plugs to all crank pits, gearcases, inclusive of transmission and differential housings, with generous oil holes.

The clutch would be multiple disc with 52 steel plates running in oil and with a generous carrier. The transmission would be of the four-speed selective type with the following gear ratios: 1, 9 to 1; 2, 5 to 1; 3, 3 to 1; 4, 2 1-4 to 1; reverse, 9 to 1. The drive would be by shaft and the universal housings would be grease tight. I would have semi-elliptic springs on the front and platform springs on the rear. The wheelbase would be 135 inches and the tires would be 37 inches by 5 inches. The rear axle would be floating with Hess-Bright bearings, and the front one would be tubular, hot-riveted with Timken bearings. The control would be by foot and hand throttle with a cut-out button on the wheel. For brakes I would use two expanding and two Raymond contracting on the rear wheels.

The features of the body would be a seven-passenger, fore-door, straight-line body with plenty of leg room for all seats. full spring, hand-buffed, hair-filled leather seats, 30-gallon gas tank under pressure under the front seat, tool box at the rear, cowl dash, self-locking door catches.

The equipment would include a self-starter, Gray and Davis full electric light system, Warner clock and speedometer, Banker windshield, pressure, volt and ammeter gauges, oil sights, Continental quick-detachable, demountable rims with two extra rims carried at the rear of the body in a special cradle fastened to the rear from a cross piece, Goodrich tires carried in a metal trunk along with tubes, jack and pump, storage battery to be carried under the rear seat, all wires leading from it to run in lead conduits. The object would be to keep the running boards free from all boxes or tanks.

The top would be of the best mohair, five-bow, strap-hung. The cushions and tire covers would be of the same material. The top of the frame would not be over 25 inches from the ground, and the seats would be comfortably low.

The weight of the car would not be over 4,000 pounds and its price would be somewhere around $5,000. F. E. D.

Haverhill, Mass.

Co-operative Manufacture

Editor THE AUTOMOBILE:

Many of your readers have described their ideal cars for 1912. From the size of the cars desired, most of the descriptions seem to come from married men with large families.

My needs would be better filled by a small car—a dependable runabout. I prefer a two-cylinder car to many of the fours which have a stroke barely in the plurality of inches. Many experts have spoken in favor of the two-cylinder engine for cars of 20 horsepower and below. Therefore, let the engine have two cylinders, opposed, under the hood, with a bore of 4 3-4 inches and a 5-inch stroke. This would give full 18 to 20 horsepower, if properly constructed.

The hood should be of the Renault pattern, well raised. The transmission should have three speeds, of course, and selective; geared three to one, but with the low so low that the engine would pull a full 30 horsepower on hills. The clutch should be of the multiple-disc type with enough plates to avoid grabbing, and the wheels should be 34 inches in diameter with 3 1-2-inch tires. I would put an 18-gallon gasoline tank under the seat, and make a large tight-closing carrying space in the rear.

This runabout would be primarily for two passengers, but the seat should be made undivided and large enough for three in a pinch. The tool box should be put on sturdy running boards, and enough of the inner side of the front mudguards should be clipped out to give the driver a clear view of the front rims. Mud will not spray through this aperture to any extent, and it is a great convenience to see just exactly where you are driving the front wheels in tight places.

A manufacturer making such a runabout of good materials with the best grade of workmanship, selling it direct to buyers and giving 5 per cent. off on club orders of three or four, and 7 per cent. off on those of five or more, ought to make a good profit at $500 for each car. In one active season, without exaggerating the intended output, the maker ought to sell 15,000 of these machines. The price could then be lowered 20 per cent. and at least 20,000 more such runabouts sold with but little advertising.

The apples of profit in the co-operative field of automobile making are as ready for plucking as was the over-ripe fruit in the garden of the Hesperides.

Seattle, Wash. S. ROSS PARKER.

Automobile Metallurgy Made Easy

By E. F. Lake

Part IV
Torsional Strains

THERE are many parts of an automobile which are submitted to torsional strains, that is, twisting strains. While it is possible to get from the tensile strength, elongation, etc., an idea of the torsional strains a metal will stand, these do not tell the whole story. Steel might show a good resistance against being pulled apart and thus have a high tensile strength, and yet not be tough enough to withstand high twisting or torsional strains. On the other hand, a steel might only have a medium tensile strength and still withstand very high torsional strains.

In the tensile testing machine the molecules of the mass are separated by being pulled away from one another in a straight line, while in the torsional strains these molecules must slide past one another until their cohesive force has been destroyed enough for the metal to break. Cylindrical pieces A, B, C and D in Fig. 1, show the manner in which torsional strains affect materials. The fine lines in A outline a plane, from the center to the circumference of a round bar before it is twisted or torsional strains are applied. Piece B shows the position this same plane occupies when the bar has been twisted. Piece C shows an elementary sector of this same round bar before being twisted, and D shows it after it has been twisted. These latter two illustrate the manner in which the particles of the mass must slide by one another when a material is given a torsional strain. Toughness, hardness, ductility, density and cohesion are all factors that affect the torsional strains that materials will withstand.

Many of the most vital parts of an automobile are submitted to these torsional strains and hence torsion tests are of nearly as much importance as those for tensile strength, elastic limit, elongation and reduction of area. They are made on a different machine, however, and consequently many rely on the tensile test to indicate what the metals will stand. The crankshaft of the engine, in particular, is given a sudden torsional strain every time an explosion occurs in one of the engine cylinders and when a car is moving this occurs almost continually. From there the torsional strain is transmitted to the different shafts in the gearbox. It is then transmitted through the universal joint to the driving shafts and mechanism of the rear axle. Where the chain and sprocket are used for transmitting the power to the rear wheels the strain may follow a little different course but the principle is the same and it affects nearly all driving parts between the crankshaft of the engine and the rear wheels.

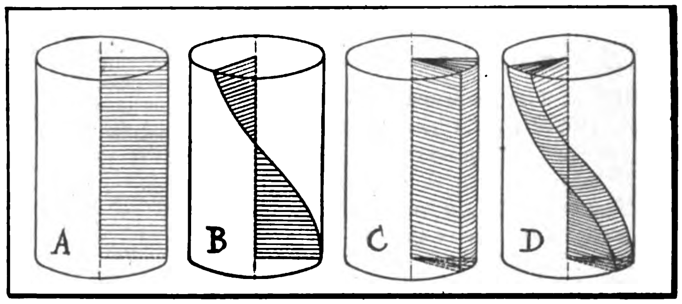

Fig. 1—How torsional strains affect materials

The camshaft is submitted to slight torsional strains as well as all other parts that revolve. When driving a car over a rough road, the front axle is also submitted to torsional strains. Here, however, the strains alternate back and forth in opposite directions, an effect which is not produced in any of the revolving shafts of the mechanism. True, the backing up of a car causes torsional strains to be delivered to the driving parts in an opposite direction to that transmitted when it is being driven ahead. This, however, is not the sudden change in direction that takes place in the front axle and, consequently, can be ignored. Likewise, the frame is submitted to this twisting strain that suddenly changes in direction.

As these torsional strains affect all of the important moving parts of a car, as well as the frame, front axle, etc., they are factors that should not be ignored in the testing of materials and the tensile strength should not be taken as an indication of a material's resistance to torsional strains. The torsional resistance varies greatly in the various metals used. Cast iron is a hard, brittle metal and resists torsional strains very poorly. Aluminum, on the other hand, is comparatively soft and plastic and this also resists only slight torsional strains. Both of these metals however, are lacking in toughness, density and cohesive force, which may account for their low torsion.

Brass will show a higher torsion than either of these but yet is not a metal that is high in torsional strength and hence should not be submitted to such strains. Some of the bronzes are very tough and will withstand very high torsional strains. Notable examples of these are manganese and tobin bronze.

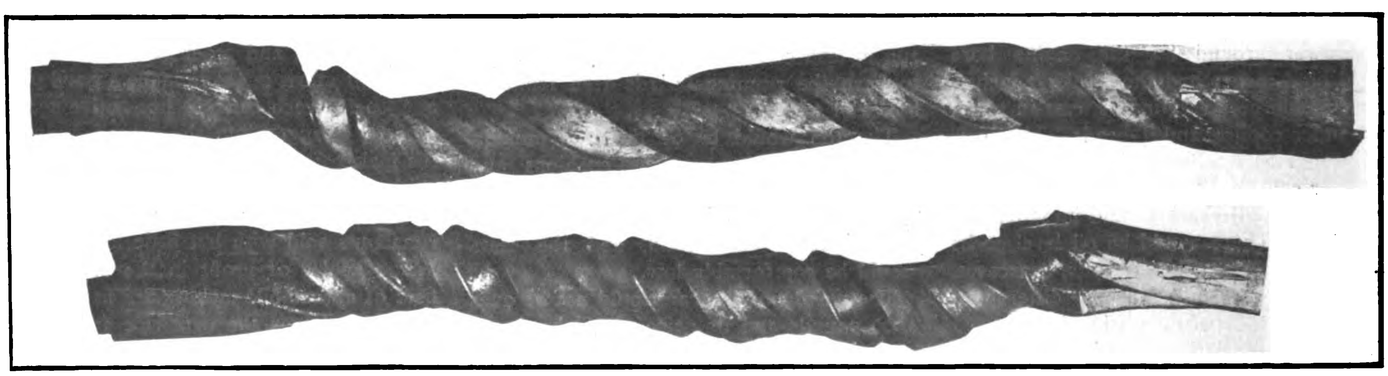

Fig. 2.—Specimens of automobile front axles after the torsion test has been applied

Steel has a higher resistance to torsional strains than any of the other metals and, consequently, it is used for the important parts that have to withstand such strains. There is, however, a great difference in steels and some do not have as great a torsional strength as the bronzes mentioned. The two specimens of front axles that are shown in Fig. 2 give a good illustration of this.

The lower axle was made from low carbon steel and when a torsional strain of 15,700 pounds per square inch was applied it twisted through four and one-half complete revolutions in its length of 24 1-2 inches; the elastic limit of torsion occurred at 3,500 inch pounds.

The upper axle was made from one of the special alloy steels often used in automobile construction and when a torsional strain of 30,700 pounds per square inch was applied, it only twisted through three and one-half complete revolutions in the same 24 1-2 inches of length. The elastic limit of torsion in this latter axle was not reached until 7,540 inch pounds had been applied. It will thus be seen that the high grade alloy steel had double the torsional properties possessed by the low carbon steel.

Like the other strength properties, torsion is greatly affected by heat-treating steel. If steel is heated to a high temperature and suddenly quenched in water or brine, its toughness is gone and it is very brittle. Its resistance to torsion therefore would be very low. On the other hand, if this hardness and its resultant brittleness were reduced by tempering the steel, that is, reheating it to comparatively low temperatures and then cooling it, its torsional resistance will be greatly increased. Some of the alloy steels, such as nickel chrome, will give very high torsional resistance figures when they have been properly heat-treated.

A Real Rubber Solution—In the *Moniteur Scientifique* for September F. Ahrens indicates the means for obtaining true and highly adhesive solutions of rubber. In the so-called solutions of rubber in benzine, gasoline, benzol and toluene the rubber is only swollen, and merely a colloidal suspension is produced which, thrown on a filter, immediately separates into its two constituents, *viz.*, the colloid and the fluid which causes it to swell. By employing raw Para rubber and operating under certain conditions which the author indicates solutions which are very binding and of high viscosity are obtained, and the rubber conserves its original structure almost completely. But if it is triturated the solution becomes much more subject to oxidation and loses some of its adhesive property.

By employing amyl acetate as a solvent and treating very thin slices of cleaned and skinned Para, the author has succeeded in obtaining true solutions which will pass through an ordinary paper filter without assistance from suction or pressure, though very slowly. The filtered fluid is of amber color and its fluidity it like that of castor oil.—From *Le Génie Civil*, November 25.

Oxy-Gasoline Flame for Welding and Soldering—According to a somewhat indefinite report, gasoline, benzol, kerosene or alcohol may handily be used in the place of acetylene gas for autogenous welding or for soft soldering. To this end, the oxygen generator is simply connected by pipe or hose with a tank containing one of the fluids mentioned, and from it the gas mixture is piped under pressure to the burner, where, the report says, it is heated by means of a small lamp. The flame is rather large, it is admitted, but the purity of the gas excludes all clogging of the nozzle, while the fuel is more universally obtainable than acetylene or hydrogen and considerably cheaper.—From *Metall-Technik*, October 7.

From Either Side

WHERE do we stand? Mr. A. writes and asks why American automobile builders do not wake up and do something; then comes a letter from Mr. B., who says that America is making greater progress in the art and design of the automobile than any foreign land. Both claim to be right. Mr. A. in defense of his claim points to the progress shown at the recent Olympia exhibition. England has adopted worm drive for touring cars; she has accepted the detachable wire wheel; she took up the sleeve-valve motor four years ago; she has brought out the piston-valve motor; she has recently marketed the new type of single-sleeve valve; she has gone in a wholesale way into four-speed gearboxes; she introduced to the world the fore-door body type; and for a couple of years has been pushing ahead in the development of carbureters, so that six-cylinder cars can average 24 miles per gallon of fuel between London and Edinburgh. This is quite a long and worthy list of achievements—a list that shows engineering and manufacturing activities. But what has Mr. B. to say? He points to the many things that American makers were doing four or five years ago, and which things Europe is just working at to-day. The supplementary coil spring to be used in conjunction with rear springs was brought out and used extensively on this side of the Atlantic over five years ago, and it is just having its innings abroad at present. In Paris one maker is getting more profit out of his factory for these springs than are several of the car builders out of their factories. Thanks to our poor roads we had to have them years ago in order to drive with any degree of comfort over country roads.

Take more important examples: Europe is to-day imitating America in the matter of unit construction of the motor and gearbox. For three or four years this tendency has been gaining ground very rapidly with American makers, and it shows many converts in Europe for next season, one of the most conspicuous being the pioneer Panhard. The American design in which the gearbox is formed as a unit with the rear axle is also showing many gains, not a few of the leading builders—including Sheffield-Simplex, one of the finest engineering houses in England—using this construction for next year.

For several years it has been general in Europe to put one set of brakes on the rear wheel drums and to have the other set on the propeller shaft immediately in rear of the gearbox. During such time American makers were putting both sets on the rear axle. Now Europe has taken up the rear axle scheme and there is a virtual stampede towards it. While America was not the originator of the rear wheel double-brake idea, she was certainly its exponent, and demonstrated that it is correct.

But we must be fair and look at the other side of the picture: Europe was ahead of us on the non-poppet valve motor. Knight had to go to London to get recognition for his double-sleeve valve. He was a prophet without honor in his own land. He mounted into almost instantaneous fame abroad. Daimler, Mercedes, Panhard and Minerva gave him the open door and then the entire world was interested. There were more American engineers visiting Coventry than there were French, German or English. Europe took up the Knight motor and America rushed to get into the band wagon. This was Europe's inning. England set the pace in the lubrication field for motors. De Dion was the pioneer in the non-splash system that is gaining so many adherents to-day, and an American abroad introduced the trough system for oiling the lower connecting rod bearings. Mercedes and many of the other big concerns now interconnect the accelerator pedal and the throttle control with the motor lubrication system, so that when the throttle is opened more oil is fed. In America the users of the Knight type of motor for 1912 use the same system. It is a commendable one, and should be imitated. There are various ways of doing it: Panhard works it by a vacuum control from the mixing chamber of the carbureter, whereas others use the hinged trough as brought out by the Daimler people.

What is the end of the whole matter? There are scores of examples of good pioneering work on either side. It would seem that Europe has been the pioneer in more good things than America, but that America has been quicker to take up a good idea, and the makers in general have adopted it more readily than in Europe. In France and England many individual builders have brought out excellent designs, but it has taken years for the other makers to adopt them, whereas in America imitation is much quicker and vastly more general. Europe has done much experimenting along lines that have not proven desirable for one reason or another. The front-wheel brake is an example of this. So with the matter of side-sway devices to prevent the rear end of the body swaying out too far in taking a curve at speed. It is well to have all these problems settled, and while Europe has been settling hers America has been doing her part. Both are working towards the ultimate; one is of assistance to the other. Europe carried the burden almost entirely at the start, but America is doing nobly at the present time. In America the big problem has been production; in Europe this phase of the situation has not been paramount excepting in a few cases. The Society of Automobile Engineers in America will do and is doing much to develop the pioneering spirit on this side of the Atlantic.

The Legal Field—Allen Suit Proceeds

THE various bumps suffered by the Allen-Kingston Motor Car Co., in 1907, came under the spotlight when the suit of that concern against the Consolidated National Bank and three bank directors came up on the calendar of the New York Supreme Court last week. One of the material witnesses of the plaintiff company is in California and the court was asked for permission to take his testimony by commission.

The facts in the case are that Walter C. Allen, of New York, entered into a contract with the Kingston Motor Co. to build 100 cars. The undertaking of the Kingston company was guaranteed by E. R. and O. F. Thomas, New York bankers, but after six of the automobiles had been practically completed, the company announced that its resources were exhausted, including $16,500 put up by Allen as a deposit. The Thomas guarantee was worded so as to expire if the contract should be assumed by some manufacturing company satisfactory to Allen.

After some rather protracted negotiations, the contract was turned over to the New York Car & Truck Co., Allen claiming that the financing of the manufacturing project had been agreed to by the bankers. He turned back to the company the six unfinished cars and paid in $8,500 more in cash.

In March, 1906, the New York Car & Truck Co. failed and Allen sued the bank and bankers, charging that misrepresentations had been made to get him to turn over the contract to the insolvent company. On the original trial a verdict for $28,463 was given in his favor. This was carried to the appellate division and was reversed and a new trial has been ordered. The first act in the new trial was the granting of an order to take the testimony of a California witness by commission.

It is doubtful whether the full hearing of this case can be had until late in the winter. The original trial occupied several days and the record taken at that time is more than 1,000 pages of closely printed text.

Koehler Suit Against E-M-F Halted

The withdrawal of a juror in the suit for $100,000 damages brought by the H. J. Koehler Co. against the E-M-F Co., halted the proceedings abruptly in that case and will probably result in a delay of several months. The case was called for trial in Part 14 of the Supreme Court on Wednesday and had proceeded but a short time when it was discovered that a bill of complaint would have to be amended to cover a new state of facts that developed. Paul Bonynge, representing the plaintiff company, moved for the withdrawal of a juror and leave to amend the petition.

The suit is based upon alleged failure to conform to the terms of a contract that existed between Koehler and the company in 1908-1909 to represent it in the metropolitan field. The contract called for the delivery of 1,000 cars to Koehler and he contends that only 546 automobiles were so delivered. The company maintains that Koehler's contract was modified by written communications and that it holds a release from the plaintiff against liability arising out of the contract.

Rajah Company Wins Action

The International Automobile League, of Buffalo, and its president (Arthur C. Bidwell) have been adjudged guilty of contempt in violating the terms of an injunction issued against them on behalf of the Rajah Auto Supply Co. There were four counts against the league and one against Bidwell. Fines and costs were imposed.

About a year ago the Rajah company sued out an injunction against the league on the ground that it was selling a porcelain plug similar in exterior appearance to the one of the Rajah company. The injunction included Bidwell in its prohibitions.

The action for contempt was begun quite recently and was decided by Judge Lambert last week.

Another Klaxon Suit Filed

Another action has been filed by the Lovell-McConnell Manufacturing Co., of Newark, N. J., against the American Ever-Ready Co., involving the Klaxon patents. The first suit was filed December 2 in the United States Circuit Court, Southern District of New York, and is based upon alleged unfair competition and imitation of the three basic patents covering the Klaxon warning devices.

The second suit is formulated upon two of the detail patents controlled by the plaintiff company and a third suit, covering the design patents, is being prepared for filing.

The bill prays for an injunction, damages and an accounting.

National Wins Its Axle Suit

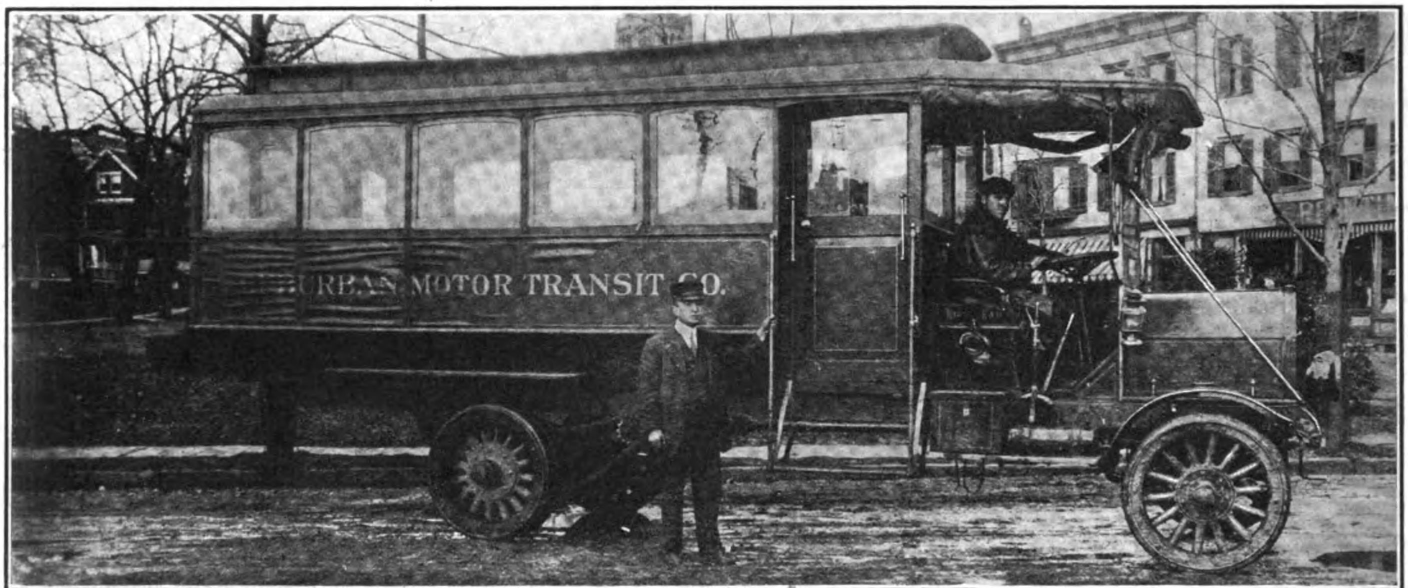
When the suit of Lindsay & Harmon against the National Motor Vehicle Co. was dismissed by the United States Circuit Court at Indianapolis, one of the really momentous litigations of the year in the automobile world was settled. The case involved an attempt to establish the exclusive right to manufacture floating axles for the licensee of the complainants, the Timken Axle Co. of Detroit. The case has been pending since 1905 and was argued before Judge Anderson last June. It was set for re-argument in November, but when the matter came up the complainants moved to dismiss it voluntarily.

T. C. A. Double Transcontinental Trip

WASHINGTON, D. C., Dec. 9—President Taft to-day gave an audience to Thomas W. Wilby, pathfinder of the Touring Club of America, and Mrs. Wilby, who arrived in Washington yesterday on the final stage of a double transcontinental tour, which started from New York the last week in August. Mr. and Mrs. Wilby were presented to the President by Leroy Mark, manager of the southeastern department of the Touring Club of America.

President Taft manifested great interst in Mr. Wilby's account of the trip across the continent and back. Commenting on the great influences at work to improve the country's highways, the President said good roads stood for the social and moral uplift of the nation. Later in the day Mr. and Mrs. Wilby were introduced to Speaker Champ Clark and a number of Congressional leaders, who evinced lively interest in the trip now nearing completion. An Ohio car, driven by Fred Clark, is being used by Pathfinder Wilby. The party will leave for New York Monday, arriving there about the middle of the week.

Mr. Wilby and his party reached New York Wednesday completing the great circuit of the country, including 11,000 miles of automobile touring. Upon arrival in New York the party were received at the headquarters of the Touring Club of America, Broadway and Seventy-sixth street. After an informal reception the tourists and escort proceeded to the Holland House, where an elaborate luncheon was served.



NEWS of the WEEK CONDENSED

New England KisselKar auto bus for regular winter service between White Plains and Port Chester, N. Y.

MILWAUKEE, WIS.—Isaac G. Hickman, president of the Hickman-Lauson-Diener Co., state agent for the Ford, was re-elected president of the Milwaukee Automobile Dealers' Association at the annual meeting. Emil Estberg, representative of the Pope-Hartford and Woods and Waverly electrics, was elected vice-president; A. E. Haffauf, of the American Automobile Co., Pierce-Arrow agent, secretary, and August A. Jonas, Cadillac and Peerless, treasurer.

PORTLAND, ME.—G. A. Blanchard has been appointed the new Selden agent in this city.

PORT ANGELES, WASH.—J. C. Leadbetter now has the handling of the Mitchell line here.

SAN DIEGO, CAL.—The U. S. Grant Hotel Garage has taken the agency for the National 40.

DEFIANCE, O.—H. E. Throne has sold the repair department of the Jefferson Garage to C. F. Miller.

NEW HAVEN, CONN.—The White Motor Company has taken the agency for the Reo for this vicinity.

TRENTON, N. J.—The Trenton Taxicab Company has changed its name to the Trenton House Garage.

CHARLESTON, S. C.—The Charleston Motor Sales Co. has taken the agency for the Ford car in this territory.

ROCK ISLAND, ILL.—The Totten Automobile & Supply Company has taken the Lozier and Abbott-Detroit agencies.

PORT HURON, MICH.—The Havers Motor Car Co., of this city, has increased its capital stock from $60,000 to $200,000.

SYRACUSE, N. Y.—The W. King Smith Co. has now taken possession of its new garage at No. 106 North Clinton street.

COLUMBUS, O.—The Front Street Garage & Auto Repair Co., 286 North Front street, has taken the agency for Grabowsky trucks.

SYRACUSE, N. Y.—The local agency for the Stoddard-Dayton has added the Gramm truck to its line. A. W. Zimbrich is manager.

MONTREAL, QUE.—The International Car Agency Co., 855 St. Catherine street, West, has been appointed local agent for the Interstate car.

DYERSVILLE, IA.—J. Friedman, of this city, has contracted to handle the Continental, Kisselkar, E. M. F. and Flanders lines for 1912.

PEORIA, ILL.—The Peoria Auto Co. is now handling the Waverly Electric, for which the Bourdeaux company was the original agency.

CLINTON, ONT.—The Clinton Motor Car Co., Ltd., is the title of a newly incorporated company in this city with a share capital of $100,000.

LOS ANGELES, CAL.—The Studebaker Company's Southern California branch is established in its new home at 1620 to 1624 East Seventh street.

TACOMA, WASH.—J. A. Croston and A. E. Sweet, proprietors of the Sixth Avenue Garage, have secured the agency for the Buick car in Tacoma.

PEORIA, ILL.—The J. C. Warner auto agency has signed a contract with the Metz runabout company to handle the Metz 22 during the coming year.

NEW YORK CITY—The H. W. Bell Company, agent for the Stanley steam car in New York and vicinity, has removed to 247 West Fifty-seventh street.

OMAHA, NEB.—The Lininger Implement Co. closed a contract with E. G. Minnix, of Sioux Falls, S. D., for 125 R. C. H. and Oakland cars for that territory.

BOSTON, MASS.—H. R. Smith, formerly district manager for the Metzger Motor Car Co., is now traveling salesman for the J. S. Harrington Co. in New England.

ATLANTA, GA.—W. T. Downing has prepared plans for a five-story, reinforced concrete building to be erected for the Buick Motor Car Co. at a cost of $50,000.

NEW YORK CITY—The Gallagher-Tompkins Co., of 1876 Broadway, is the newly appointed metropolitan agent for the Selden Motor Vehicle Co., of Rochester, N. Y.

BOSTON, MASS.—B. W. Shaw, formerly in charge of the Park Square Auto Station, has taken charge of the service station of the Empire motor car agency in this city.

BOSTON, MASS.—General sales manager Baker, of the American Motor Car Company, has been in Boston aiding manager Doane of the Essex Automobile Company, agent for the American car, in getting settled in the new salesrooms on Boylston street.

BOSTON, MASS.—In the Middlesex County Court last week fifteen suits, aggregating $88,500, were filed against automobilists. The largest is one of $30,000 against George F. Schraft, a wealthy confectioner of Newtonville, whose car killed Felix Chesnovich in September.

BUCYRUS, O.—Wilbur S. White has taken the agency for the Marion car.

WASHINGTON, D. C.—Earle & Allen have taken the agency for the R. C. H. car.

STERLING, ILL.—M. R. Thackaberry, local agent for the Cole car, has moved from 316 First street to 601 West Third street.

BOSTON, MASS.—J. H. Crocker is the latest addition to the sales-force of the New England branch of the Marquette.

INDIANAPOLIS, IND.—W. T. Hutchinson, of Hempstead, L. I., and Winthrop Pier, El Centro, Cal., have been appointed agents for the Cole car.

WASHINGTON, D. C.—Earle & Allen, agents for the R. C. H. and Hupp-Yeats, have removed from 1612 Fourteenth street, N. W., to larger quarters at 1214 Eighteenth street.

CAIRO, ILL.—Glenn Tracy has purchased the automobile sales business of Wood, Gorham & Wood, of this city, and will handle the Ford car in the eastern part of Henry County.

AUBURN, N. Y.—George H. Leonard has secured the contract to sell Franklin automobiles in this territory under the supervision of the Syracuse branch of the Franklin Automobile Co.

NEW YORK CITY—The Colonial Sales Co. has taken the distributing agency for the G. J. G. car. The company is located in the Colonial building at Broadway and Sixty-sixth street.

WASHINGTON, D. C.—W. Elkins Reed has opened an automobile supply house at 1218 Connecticut avenue. T. Lamar Jackson, agent for the Stevens-Duryea, has leased a portion of the store.

NEW YORK CITY—Chas. E. Riess & Co., general distributors of the Marion car and the American-Marion Sales Co., have moved into their new quarters at Broadway and Sixty-third street.

WAKEFIELD, MASS.—At the fall town meeting the recommendation of a committee that the town purchase a motor fire truck was accepted and $3,800 was appropriated for the purpose.

MOLINE, ILL.—Jack Stickney, of the Velie Motor Vehicle Co., has bought a Bleriot monoplane and will take up aviation in the spring. He is now experimenting with a motor for the machine.

SEATTLE, WASH.—Organizing in this city recently the Motor Distributing Co. will hereafter handle the Lozier car. T. A. Davis is president and treasurer and T. G. Young secretary and manager.

BOSTON, MASS.—The J. S. Harrington Company, agent for the Everitt car, has appointed J. H. Burkhard traveling inspector. Mr. Burkhard was formerly in charge of the Everitt service station.

SYRACUSE, N. Y.—George E. Messer, manager of the Syracuse branch of the Franklin Automobile Co., has resigned to become sales manager for F. W. Bird & Son, paper manufacturers, of Boston, Mass. Mr. Messer will have charge of the Western territory.

INDIANAPOLIS, IND.—The following Cole agents have new salesrooms and service stations: E. E. Loving Auto Co., Memphis, Tenn.; Imperial Motor car Co., Cincinnati, O., and J. E. Morehouse, Milwaukee, Wis.

OKLAHOMA CITY, OKLA.—The Penn Motor Car Company, of Pittsburgh, Pa., has designated Oklahoma City as its southwestern distributing point for the Penn 30 and the Penn 40 and light delivery trucks.

OKLAHOMA CITY, OKLA.—According to the annual report of the state auditor, made from the certified report of the county tax boards, there are 3,459 automobiles in the State. A total value of $2,648,845 is given.

ST. PAUL, MINN.—The new automobile tags for this state are of aluminum in which the black lettering is sunk. Under the new law these tags will be good until the end of 1914 instead of for only one year.

COLUMBUS, O.—The Union Sales Co. has appointed the following agents for the Union 25: Crowe Motor Car Co., Minneapolis, Minn.; Marx Bros., Milwaukee, Wis., and McNabb Garage, Newport, Tenn.

CHICAGO, ILL.—F. H. Quick, formerly with the Gibson Auto Company, of Indianapolis, Ind., and United Motors Indianapolis Company, has joined the sales force of the Findeisen & Kropf Manufacturing Company.

JANESVILLE, WIS.—The Sykes & Davis Garage has passed into the hands of the Janesville Auto Company, a new $10,000 corporation formed here to handle the Flanders, E. M. F. and Overland lines in Rock County.

MILWAUKEE, WIS.—The report of the building commissioner of Milwaukee from 1896 to 1910, just issued, shows that during the year 1910 there were constructed in Milwaukee eighty garage buildings, representing an investment of $107,350. The record for 1911 will show a considerable gain over these figures.

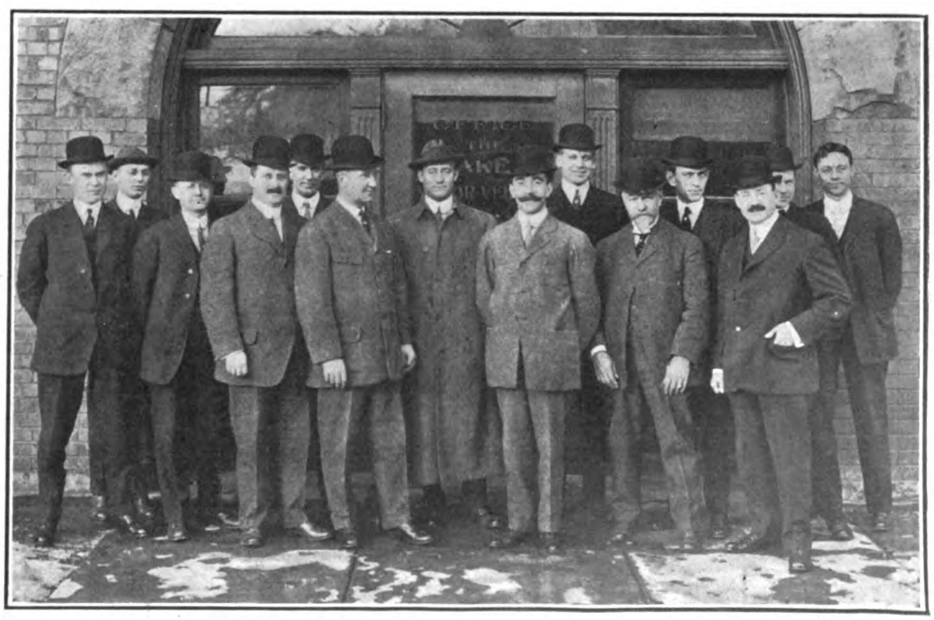
CINCINNATI, O.—H. E. Taylor has resigned his position with the Automobile Supply Company of Chicago to join the sales force of the Olds-Oakland Motor Company. Mr. Taylor will have charge of the local retail business.

AKRON, O.—The Swinehart Tire & Rubber Co., this city, has under consideration plans for a large addition to the plant on North Howard street. The new building will be 50 by 200 feet and will be built just west of the present plant.

MONTREAL, QUE.—John Wells, formerly manager of the tire department of the Canadian Rubber Co., of this city, has resigned to take the position of sales manager of the P. Gadbois Co., representative for the Cole and E-M-F in eastern Canada.

DETROIT, MICH.—The Elmore Automobile Company, of this city, is now occupying its handsome new home at 754-756 Woodward avenue. The building, which is two stories in height, is of brick and concrete and is furnished with large show windows. M. A. Young is president of the company, which handles the Elmore cars and the Waverley Electrics.

CLEVELAND, O.—The Baker Motor Vehicle Company recently held a convention of its commercial car salesmen at the factory. Representatives were present from various parts of the country, including New York, Boston, Chicago, Buffalo and Newark. Salesmanship, factory methods and the company's product were studied for three days. The convention ended with a banquet at the Hollenden.



Convention of Baker commercial car salesmen at the factory

President Taft in a KisselKar at Huron, S. D., during recent Western trip

GREEN BAY, WIS.—Tooen & Barlament are erecting a $5,000 garage and sales-office building at George and Wisconsin streets.

MILWAUKEE, WIS.—J. M. Peil, of Racine, Wis., has been appointed manager of the local Mitchell branch to succeed F. P. Wilkins.

OAKLAND, CAL.—Curtis G. Heckenlively, of this city, has been appointed Pacific Coast distributor for the Universal Tire Protector Co., of Angola, Ind.

TORONTO, ONT.—The Cutting Motor Sales Co. of Canada, 76 Adelaide street, has been appointed wholesale distributor for Canada of the Cutting car and is busy placing agencies in large Canadian cities.

SYRACUSE, N. Y.—R. W. Sherman has resigned from the publicity department of the Franklin Automobile Co. and will devote his time to special writing in connection with automobile trade publications and newspapers.

MILWAUKEE, WIS.—The Jos. Obernberger Co., 126 Ferry street, has been appointed local agent for the Monitor commercial car, manufactured by the Monitor Automobile Works, of Janesville, Wis., formerly of Chicago.

NEW YORK CITY—New salesrooms have been opened by the Ajax-Grieb Rubber Co. for the sale of Ajax tires in Detroit and Denver. In the Michigan city a move has been made to 507 Woodward avenue, from 745 Woodward avenue.

DETROIT, MICH.—P. S. Beamer, who has been associated with President Everitt of the Metzger Motor Car Co. for a long period, has been made general auditor of that company and will have entire charge of all accounting and similar work.

ROCHESTER, N. Y.—The Selden Co. has opened a new salesroom at No. 119 East avenue. This is a branch of the factory used for sales purposes only, as the repair department is still maintained at the factory. W. C. Barry, Jr., is in charge.

ADRIAN, MICH.—The following agents have been appointed by the Lion Motor Car Co. of this city, to handle its 1912 line: Reliance Auto Co., San Francisco, Cal.; F. W. Hull, Boston, Mass., and the Joseph B. Deibler Motor Car Co., Chicago, Ill.

SHEBOYGAN, WIS.—August H. Prange, dealer in motor cars and farm machinery at Potter, Wis., has disposed of his interests in that city to Piepenburg & Reichert, of Reedsville, Wis., and will engage in the automobile business in Sheboygan.

TORONTO, ONT.—The Wolseley Tool & Motor Car Co., Ltd., has opened a Canadian branch here and is at present in a temporary office at 49 Wellington street, East, pending the erection of its new garage and salesroom at 81 Avenue road.

WACO, TEX.—William Amthor has retired from the firm of the Marion Auto Company. He sold his interest in the business to Grim Brothers, who will conduct business under the name Marion Motor Company at the same location, 700 Austin avenue.

WAUKESHA, WIS.—The Waukesha Motor Co., with 100 employees, has elected to come within the provisions of the new Wisconsin industrial insurance or workmen's compensation act, which was declared constitutional by the state supreme court several days ago.

MILWAUKEE, WIS.—The Kopmeier Motor Car Co., 375-389 Summit avenue, agent for the Fiat, Chalmers and Detroit Electric, has placed in service a 150-horsepower gas engine as additional equipment for the production of current for charging electric vehicles.

DETROIT, MICH.—George Main, formerly assistant traffic manager at the Chalmers plant, has been appointed traffic manager at the Metzger Motor Car Co. plant. Mr. Main has been connected with the traffic service for many years and is regarded as an expert in his line.

DETROIT, MICH.—George B. Pratt, formerly sales manager of the Dean Electric Company, of Elyria, O., has joined the sales force of the Anderson Electric Car Company. Mr. Pratt will have charge of sales in Ohio and in part of New York and Pennsylvania.

CHICAGO, ILL.—F. W. Grubb, of the Fulton & Grubb Co., manufacturers' agents, has severed his active connection with that company to accept the position of manager for the Excelsior General Supplies Co., 1436-1438 Michigan avenue. Mr. Grubb retains his financial holding in the Fulton & Grubb Co.

PEORIA, ILL.—On December 15 Braren Brothers, proprietors of the Turnbull agency and garage here, will commence handling the Flanders electric and White gasoline cars. They have also contracted for the agency for the Moon car, previously held by the Reliance Motor Car Co., of this city.

SALEM, ORE.—The automobile department of the Secretary of State's office recently received 6,000 numbers or 12,000 tags, weighing over 7,000 pounds, for use in registering automobiles during 1912. In addition, 2,000 chauffeurs' badges have been ordered. The number tags, which are issued in duplicate, have black figures against a green background.

SEATTLE, WASH.—The largest building permit issued in Seattle recently was issued to Olaf Olson, providing for the immediate erection of a two-story class A garage designed for four stories and covering a ground space 80 by 120 and 40 by 40 feet. The garage will be located at 1205-1211 East Pine street and will cost $28,000.

SYRACUSE, N. Y.—B. J. Lane, of The Lane Auto Association, has taken over the management of The Syracuse Regal Co. and will act as the distributor of the 1912 Regal line as well as the KlineKar. Both The Syracuse Regal Co. and The Lane Automobile Association will have headquarters at No. 1205 West Genesee street.

TOLEDO, O.—The board of review is having a list made of all automobiles owned in the city as shown by the state license records for the purpose of enforcing the payment of taxes on machines, many of which have heretofore escaped taxation According to the president of the board only about one-half of the automobiles owned in Toledo were returned for taxation last year.

DETROIT, MICH.—Charles W. Price, president of the Electrical Review Publishing Co., announces the purchase of *Electrocraft*, an electrical journal largely devoted to electrical contracting and electrical supplies. Three electrical journals, the *Electrical Review*, the *Western Electrician* and *Electrocraft*, will, after January 1, appear as one weekly publication with main offices in Chicago and branch offices in New York and London.

PITTSBURGH, PA.—The Pittsburgh Inter-State Co. will handle the Stutz and Warren cars during the coming year.

BOSTON, MASS.—Chief engineer Wicks of the H. H. Franklin Co. has been spending several days at the Gray & Davis lamp factory going over details of equipment for automobiles.

PORT HURON, MICH.—Mr. B. F. Blaney, formerly general sales agent for the Johnson Service Co. of Milwaukee, has taken the position of sales manager for the Havers Motor Car Co.

SAN FRANCISCO, CAL.—The C. & F. Motor Car Co., has opened a salesroom at 436 Van Ness avenue, and will handle the Stutz car, manufactured by the Ideal Motor Car Co., of Indianapolis.

BOSTON, MASS.—John Cooper, formerly manager of the New England branch of the Ajax-Greib Rubber Co., has returned to the tire industry and is now representing the Endurance Tire & Rubber Co., in this territory.

INDIANAPOLIS, IND.—Paul P. Willis has been appointed advertising manager for the National Motor Vehicle Co. Mr. Willis was formerly automobile editor of *The Indianapolis Star*. He is secretary of the Hoosier Motor Club.

BUCYRUS, O.—The Seagraves Co. of Columbus, O., delivered to the fire department of Bucyrus, O., a new auto fire truck. The engine is of 80 horsepower and carries 1,200 feet of hose as well as ladders and chemical appliances.

INDIANAPOLIS, IND.—The recently organized Merchants' Auto Co. of Indianapolis has taken over the Delaware Garage at 214 North Delaware street and the new Colonnade Garage at 9 East Pratt street. E. Frank Brown has recently become general manager of the company.

COLUMBUS, O.—*The Exhaust* is the name of a new monthly publication issued by the Columbus Automobile Club. Club news, notes of the good roads movement and other matters of interest to automobilists generally will be contained in the publication. Allen F. Koch is editor.

COLUMBUS, O.—The Cummins Auto Sales Co., of North Fourth street, has placed the following sub-agencies in Ohio territory; E. O. Fogle, automobile company, Cambridge, Elmore; D. S. Spangler, Thornville, Elmore; R. E. Wildermuth Automobile Co., Pleasantville, Krit.

COLUMBUS, O.—The Hudson Sales Co., of North Fourth street, Columbus, O., has closed contracts for the following sub-agencies: J. R. Armstrong, Lima, Hudson; in Allen, Van Wert, Mercer and Auglaize counties; Walker & Son, Lancaster, American, in Fairfield, Pickaway, Ross and Fayette counties.

INDIANAPOLIS, IND.—A contract for the delivery of its papers to news-stands, depots and sub-stations has been let by *The Indianapolis News* of Indianapolis, to the Central Transfer and Storage Co., of that city. The transfer company has purchased for the work five Mais trucks, four Premier trucks, one Overland truck and a Reo truck.

BALTIMORE, MD.—Announcement has been made by A. Maurice Eastwick and Robert F. Kaehler that the partnership of the local branch of the Ford Auto Co., handling the Ford cars in Maryland and Virginia, has been dissolved. Mr. Eastwick will continue in charge of the local agency, which will also include the state of Maryland, while Mr. Kaehler will remain in charge of the Ford Auto Co., in Richmond, Va., as agent for the Ford Car in that city and the remainder of Virginia.

Automobile Incorporations

AUTOMOBILES AND PARTS

BROOKLYN, N. Y.—Prudence Motor Truck Co.; capital, $100,000; to build freight automobiles. Incorporations: Herbert Cooper, Arthur Cooper, Alfred G. Leomans, Charles G. Diegest, Franklin C. Haven.

CAMDEN, N. J.—Penn Motor Car Co.; capital, $500,000; to build motor cars. Incorporators: V. A. Murray, L. A. Myers, Doering Ballinger.

MILWAUKEE, WIS.—Wisconsin Auto Sales Co.; capital, $20,000; to sell automobiles. Incorporators: George P. Hewitt, R. L. Anderson.

NEW YORK CITY.—New York Motor Works, Inc.; capital, $70,000; to build automobiles and engines. Incorporators: M. L. Rogers, S. E. Roberson.

NEW YORK CITY.—Gurlitt-Brown-Davis Co.; capital, $25,000; to make and sell motor vehicles. Incorporators: H. Gurlitt, David S. Davis, Jr., V. C. Bogardus.

NEW YORK CITY.—Detmar Auto Sales Co.; capital, $20,000; to manufacture and sell automobiles and engines. Incorporators: John J. McLaran, F. B. Knowlton, Edward C. Inderlied.

NEW YORK CITY.—Wishart-Dayton Auto Truck Co.; capital, $25,000; to manufacture automobiles. Incorporators: R. A. Inch, S. E. Wishart, J. B Smith.

NEW YORK CITY.—Parker Motor Wagon Co.; capital, $10,000; to make and sell motor cars Incorporators: Harry C. Cottfried, Drew McKenna, Chas. E. Wood.

NEW YORK CITY.—Mooer Auto Co.; capital, $450,000; to make automobiles. Incorporators: E. J. Bosse, G. Leveene.

NORTHAMPTON, PA.—Siegfried Motor Car Co.; capital, $10,000; to sell automobiles.

PHILADELPHIA, PA.—C. V. Stahl Motor Co.; capital, $5,000; to sell motor cars.

RICHMOND, VA.—American Adjustable Wheel Co., Inc.; capital, $100,000; to manufacture and sell adjustable automobile wheels. Incorporators: J. H. Pinner, J. C. Davis, R. H. Bruce.

ROANOKE, VA.—Roanoke Motor Car Co.; capital, $25,000; to sell automobiles. Incorporators: Frank Welch, Sr., J. E. Shickle, Frank Welch, Jr.

ROCHESTER, N. Y.—Turk & Brown, Inc.; capital, $10,000; to manufacture motor vehicles. Incorporators: Sophie H. Brown, Alfred H. Brown.

SELMA, ALA.—Central Alabama Motor Car Co., Inc.; capital, $1,500. Incorporator: George H. Ashburn.

SPRINGFIELD, ILL.—Flexo Motor Co.; capital, $30,000; to manufacture engines. Incorporators: Fred C. Miller, Wm. Wishart, Henry L. Smith.

WILMINGTON, DEL.—Williams Steel Wheel, Rim & Tire Co.; capital, $1,000,000. Incorporator: William E. Williams.

WINDSOR, ONT.—Canadian Two-in-One Auto Co.; capital, $200,000; to manufacture automobiles.

AUTOMOBILES, GARAGES, ETC.

BOSTON, MASS.—Morsa-McDonald Co.; capital, $15,000. Incorporators: John D. McDonald, John S. Moore, James H. Matthews.

BUFFALO, N. Y.—Carroll Tire Co.; capital, $200,000; to make and sell rubber tires. Incorporators: John Gregson, George Cunliffe, J. E. Gregson.

CHICAGO, ILL.—F. A. L. Auto Co.; capital, $2,500; to sell automobiles and operate a garage. Incorporators: Frederick C. Harbour, Clinton S. Limb, E. N. Lundberg.

CHICAGO, ILL.—National Automobile Owners' Alliance; capital, $50,000; to make automobile accessories and parts. Incorporators: W. G. W. Ford, C. E. Becker, S. C. Miller.

NASHVILLE, TENN.—Hermitage Auto & Livery Co.; capital, $3,000; to conduct a garage business. Incorporators: L. W. Jacobs, W. F. Jacobs, E. L. Holt, T. Allison, Harry A. Stokes.

NEW YORK CITY.—Batavia Co., of Pa.; capital, $30,000; to make and sell tires for automobiles. Incorporators: Harry W. Newburger, Maxwell Lustig, D. Weiss.

NEW YORK CITY.—Cosmopolitan Motor Co.; capital, $10,000; to conduct a garage business. Incorporators: John Devine, John J. Kirby, Albert G. Armento.

NEW YORK CITY.—H. & C. Garage; capital, $10,000; to deal in, repair and store automobiles. Incorporators: Louis S. Hallowell, Herbert S. Cole, Arthur J. Cole.

NEW YORK CITY.—Security Motor Switch Co.; capital, $10,000; to make motor switches and engine accessories. Incorporators: Albert Meadows, J. E. Cleveland, E. P. Beechler.

NEW YORK CITY.—Simpson Tire Fibre Co.; capital, $100,000. Incorporators: S. L. Simpson, James D. May, Harry J. Dingemann.

PERRY, OKLA.—Automatic Motor Plow Co.; capital, $200,000. Incorporators: A. A. Hullum, S. P. Rogers, H. F. Carmichaels.

SAVANNAH, GA.—Auto Sales & Livery Co.; capital, $50,000; to conduct a garage business. Incorporators: H. W. Freeberg, E. J. Freeberg, G. R. Morehouse.

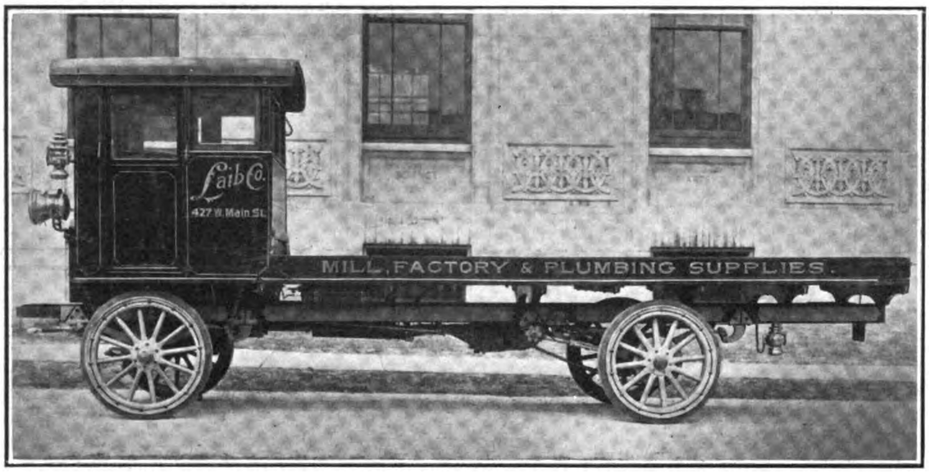
OF INTEREST to the INDUSTRY



Three-ton truck made by Transit Motor Car Company, Louisville, Ky.

NEW MARKET, ONT.—The Harding Motor Co. has decided to move from London, Ont., to this city.

PITTSBURGH, PA.—The Rotary Motor Co. has awarded the contract for an addition to its plant to the W. N. Kratzer Co.

VICTORIA, TEX.—The Texas Motor Car & Supply Company has let the contract for the erection of an addition to its machine shop.

INDIANAPOLIS, IND.—The International Metal Polish Company, of this city, has broken ground for a new factory to cost $25,000.

KEIL, WIS.—The Keil Motor Car Company, organized by Fred Theissen and Phillip Juenheimer, will build a plant here to cost $14,000.

DETROIT, MICH.—The Briggs-Detroit Co. has purchased a 2-acre factory site on Holbrook avenue from the Reinforced Concrete Pipe Co., of Jackson, Mich.

ANDERSON, IND.—Contracts have been awarded for the addition to the factory of the Remington Electric Company, which manufactures magneto ignition apparatus.

SYRACUSE, N. Y.—The Brown Company has commissioned local architects to prepare plans for a two-story brick factory here, of mill construction, 50 by 160 feet.

VANCOUVER, B. C.—The Central Auto Co., Franklin dealer in this territory, is rebuilding its garage, recently destroyed by fire. In its new quarters this concern will be in a better position than ever to handle business at this point.

DETROIT, MICH.—The Hupp Motor Company has awarded a contract for the erection of a plant at Windsor, Ont. The company has also taken out permits for the erection of a two-story brick factory to cost $65,000 at Mt. Elliot and Milwaukee avenues, in this city.

NEW YORK CITY—J. F. Hayes and W. S. Miller, formerly with the Rainier Motor Co., have incorporated a business under the name of Hayes & Miller Co. to paint and repair automobiles and to manufacture tops. The company is located at 317 West Forty-seventh street.

BUFFALO, N. Y.—George Ostendorf, formerly branch manager of the Franklin Automobile Co. in Buffalo, has purchased the branch and will hereafter conduct the business on a dealership basis under his own name. Mr. Ostendorf will retain his salesroom at No. 683 Main street.

DETROIT, MICH.—J. H. Newmark, who has been associated with the Oakland Motor Car Co., Pontiac, Mich., in the capacity of advertising manager, has been transferred to the office of the General Motors Co., Detroit, Mich., where he will assume a position as assistant to advertising manager Kurtz.

HAMILTON, O.—C. A. MacCordy, formerly connected with the advertising and publicity department of the H. H. Franklin Manufacturing Co., of Syracuse, N. Y., as superintendent of printing, has accepted a position with the Republican Publishing Co., catalogue makers of this city, as special automobile trade representative.

LOS ANGELES, CAL.—Ralph C. Hamlin, Franklin dealer in this territory, has just been informed by the Bosch Magneto Co., that he is entitled to the second prize, $75.00, offered by that company to the driver of the second car finishing in the Los Angeles desert race, provided the car driven was equipped with a Bosch magneto.

MILWAUKEE, WIS.—The Milwaukee Auto Specialty Company, recently incorporated with an authorized capital of $75,000, has selected a site for its proposed new manufacturing and sales building at Seventh and Chestnut streets. The building will be five stories high, of reinforced concrete and steel construction, and will contain a large garage.

CRANSTON, R. I.—At the plant of the Maxwell Briscoe Motor Company, here, the rush of work has been so great that some of the departments were not able to keep up with the others, and as a result about 200 men were laid off temporarily. It is expected that the men will resume work again shortly, as the demand for the cars taxes the capacity of the plant.

INDIANAPOLIS, IND.—George Bott, formerly employed by the Nordyke and Marmon Co., is the inventor of a radiator-cover which is to be manufactured by the newly organized Antidam Manufacturing Co. in this city. The cover is made of pantasote and sheet metal, fitting closely to the radiator being fastened at the top over the radiator-cap and at the bottom by the crank.

DETROIT, MICH.—The McCord Manufacturing Co. has acquired the materials, patents and good will of the Precision Appliance Co. of Chicago, and will manufacture the Hill-Precision lubricators in connection with its former product. The company has added a cellular radiator to its line. An addition of 12,000 square feet has been made to the factory building and one of 4,000 square feet to the foundry.

BOSTON, MASS.—Otto A. Lawton, formerly connected with the Franklin Automobile Co. of Syracuse, N. Y., as manager of the branch in Boston, has purchased the branch and will conduct the business under the name of the Franklin Motor Car Company, of Boston. In connection with his dealership in Franklin cars Mr. Lawton will conduct a taxicab business with stands at the Hotel Somerset and Hotel Puritan.

AKRON, O.—A 50 per cent. increase in business in the past year was reported at the annual meeting of the Goodyear Tire & Rubber Co., held this week. Big buildings have been added, new salesmen and workmen taken on and the business of the company has had marked development along many lines. Forty branches have been established throughout the country and a new office building, the latest of a series of additions, is now under construction. The officers elected are: Frank A. Seiberling, president, Charles W. Seiberling, vice-president; G. M. Stadelman, secretary; F. H. Adams, treasurer, and P. W. Litchfield, factory manager.

PATENTS GONE TO ISSUE

CARBURETER—In which the flow of fuel is regulated by a rotary valve.

5. The carbureter seen in Fig. 1 comprises a casing, in which is contained a mixing chamber for air and fuel, and a valve controlling air and fuel passage through the chamber in which a rotary fuel discharge valve is located. Valves are provided for admitting a variable supply of fuel to the pipe, and also means for effecting cooperative action of the rotary valve, admission valve mechanism and pipe, the valve mechanism being composed by a member with a recess in its face and open at its end to admit fuel thereto, a second member faced against the first and having an elongated port through it for registering with the recess mentioned, and a cap which is applied to and forms a chamber between itself and the second member. This member communicates with the discharge pipe, and one of the two members is stationary and the other rotary in the discharge pipe.

No. 1,010,714—To George J. Zisch, Newark, N. J. Granted December 5, 1911; filed May 12, 1910.

LOW PRESSURE TIRE SIGNAL—Indicates when inflation falls below a predetermined point.

This device (Fig. 2) consists of a body adapted to engage with a tire valve and having a central chamber; the body has an air inlet at its lower end and an air escape opening in its side, and in the chamber a partition is fixed between the openings thereof, the partition having a central opening. A disc is fixed in the chamber opposite the escape opening of the body and a portion of the disc is cut off. An adjustable plug is stationed in the upper end of the head, with a central rod passing through plug, disc and partition, and terminating below the latter. A valve and coiled spring are mounted on the rod.

No. 1,010,726—To Joseph M. Collins, Gorman, Tex. Granted December 5, 1911; filed January 31, 1911.

FRICTION CLUTCH—In which two conical members engage a collar, thus providing connection between driving and driven unit.

In this clutch (Fig. 3) two conical members are mounted on a shaft in spaced relation and with their conical faces opposed. One of the two cones is fixed on the shaft and the other movable toward and away from the first member, and a collar on the shaft limits the movement of the movable member.

The hub portion of a wheel is shaped to fit between the two conical faces and to rotate on them. On the collar several cams are pivotally mounted, having cams which extend radially outward. Means are slidably mounted on the shaft, by which the cams may be shifted into or out of position for holding the movable member in gripping relation with the hub.

No. 1,011,040—To John J. Dennison, Chicago, Ill. Granted December 5, 1911; filed July 1, 1911.

SPEEDOMETER—Utilizing the transmission of motion through an air current produced in the apparatus.

2. This speedometer (Fig. 4) has a tight enclosure and a hollow cylindrical member held in spaced relation to the walls thereof, so as to form an unobstructed annular space. In this cylinder air currents are produced acting upon means responsive to the air currents, these means operating a device indicating the force of the currents.

No. 1,011,051—To Louis A. Greenleaf, Dorchester, Mass. Granted December 5, 1911; filed June 9, 1910.

VEHICLE TOP FASTENER—Apparatus for securing top holding members to the body of the automobile.

2. This patent refers to a canopy fastener comprising a supporting frame having pendent lugs, and latch casings carried by the seat in a car, bolts being contained by the casings. The bolts carry means for interlocking engagement with lugs supporting tubes for the casings mentioned. Rods extending through the tubes have crank arms for operating the bolts, and means are provided to oppose the rotation of the rods in one direction.

No. 1,010,968—William Spickernagle, Owensboro, Ky. Granted December 5, 1911; filed February 6, 1911.

GAS ENGINE—Of the double sleeve reciprocating type.

3. This patent covers an internal combustion engine, with a stationary working cylinder having inlet and exhaust ports and a pair of segmental or half-cylindrical slide valves with ports disposed around the cylinder. The slide valves may be operated to bring their ports to register with the inlet and exhaust ports in the cylinder on both up stroke and down stroke of the valves. A compression-retaining ring surrounds inlet and exhaust ports both circumferentially and vertically.

No. 1,010,566—To Arthur Alltree, Manchester, England. Granted December 5, 1911; filed January 19, 1910.

INDICATING TAIL LAMP—Lamp and frame for illuminating license-plate.

1. This patent relates to an outfit comprising a frame adapted to be secured to a vehicle; a horizontal base secured to the frame and suitable lamps carried at its end by the frame. On the base is stationed a box adapted to receive lights from the lamps and containing warning mechanism. Detachable chimneys for the lamps are adapted to secure the box to the frame.

No. 1,010,806—To Maurice S. Rosenfeld, New York. Granted December 5, 1911; filed August 26, 1911.

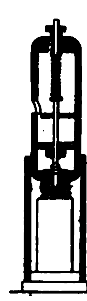

Fig. 2—Collins' tire signal

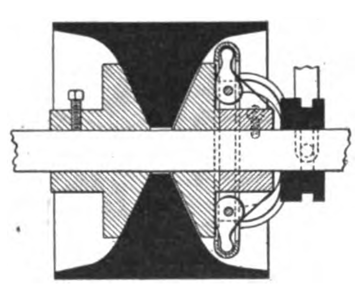

Fig. 3—Dennison clutch

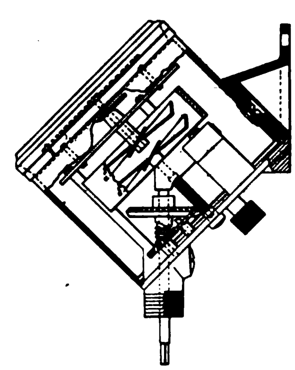

Fig. 4—Greenleaf speedometer

Newest Ideas Among the Accessories

No-Key Padlock

FIGURE 1 is an illustration of the Keyless padlock which may be used for all purposes where this type of lock is advantageously applied. The distinguishing characteristic of this device is that it is locked and unlocked without the use of a key, being complete in itself. The outside of the lock, which is finished in brass, is seen in Fig. 1. This is a front view. There are eight buttons on the front side of the lock and eight on the reverse side, and each of these buttons can be depressed. The buttons, that is, a number of them, for instance, three, are used as a combination which, if properly worked, opens the lock. The combination goes with the lock when this is bought, but no note of it is made on the lock itself. Suppose the combination reads: up, 3 and 6; down, 2. In order to open the lock buttons 3 and 6 are pressed in on the reverse side, and 2 on the front side, all at the same time. This united pressure on the buttons in the combination opens the lock instantly by releasing the male jaw, which is then thrown out of its engagement with the female jaw, while an internal spring throws up the male jaw and opens up a gap between it and the mating jaw.

More than 40,000 combinations are possible, according to the maker, on each lock, so that there is practically no chance of strangers opening the lock. It is of simple and rigid construction and lends itself for manifold uses, in locking the levers to the steering wheel or holding the gear-shift lever in neutral through the combined use of a chain and this lock. The one feature of the lock requiring no key is attractive enough, since with the use of this padlock there is no possibility of losing a key, and as a result being at a loss with regard to the locking or unlocking of the lock the key belongs to. The lock is made by the American Keyless Lock Co., 417 South Dearborn street, Chicago, Ill.

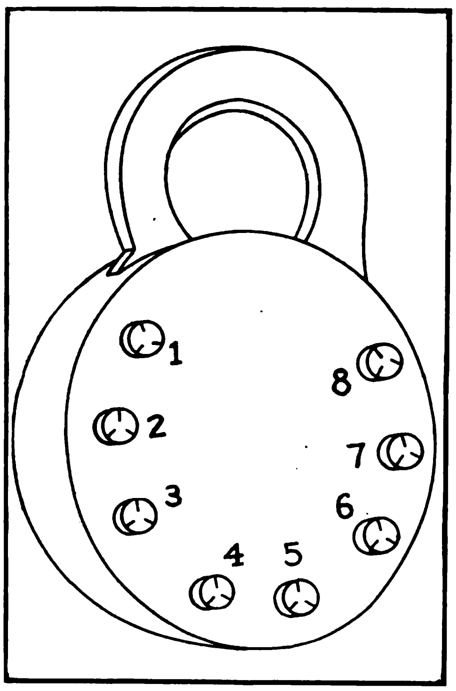

Fig. 1—Keyless padlock

D. K. W. Carbureter

The D. K. W. carbureter, which is shown in Fig. 2, is automatic in a way, in that the ratio between gasoline and air is fixed after the carbureter has once been adjusted for the needs of the engine. The automatic effect is obtained by three auxiliary valves.

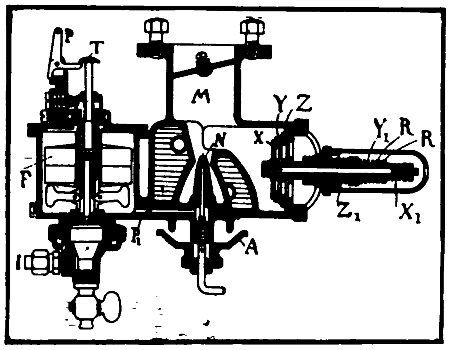

Fig. 2—D. K. W. carbureter

The gasoline on its way from the tank enters the carbureter through the inlet I, flowing up through the float chamber and passageway P1 to the nozzle N, and thence through the mixing chamber M to the intake valve of the motor. In installing the carbureter on the car, the adjustable air cup A is first placed in mid-position; then the valve stem is screwed up to close the nozzle tightly, and thereafter opened about one turn, which brings about an approximately correct aperture. The exact opening is determined by experimenting. To prime the carbureter, rod P is so moved as to lift the float valve stem at its top T, permitting the gasoline to flow into the chamber. If the motor, when running at low speeds, shows a tendency to back-fire, stem S is turned outward to enrich the mixture.

The operation of the triple auxiliary air valve is as follows: When the motor draws more air than can pass through the annular opening on top of the cup A, the first auxiliary valve X is sucked toward the motor and lifted off its seat. This permits an additional quantity of air to flow to the engine, but if the suction still increased, the additional lift of valve X compresses its spring X1 to such a degree that part of its compression is transmitted through spring retainer R1 to R and thence to spring Y1, causing the second valve Y to open and admit more air. If the suction is further increased, the last valve Z is opened and the maximum amount of air obtained. The Duquesne Auto Accessory Co., of New Kensington, Pa., makes this carbureter.

Schubert Tire Gauge

The Schubert tire pressure tester, Fig. 3, is made in the shape and size of a watch, and may be carried in the vest pocket. The case is made of highly polished nickel, the front side being as illustrated, and the reverse plain metal. The tester is operated by simply pressing the part A on the tire valve, whereby air is admitted from the tire to flow into the gauge, where it moves the finger on the dial to the position indicating the air pressure in the tire. The air or gas is retained in the gauge, which it enters through a non-return valve, and is released by pressure exerted upon the release button R. This construction of the gauge makes it possible for the motorist to make a quick test of the tire pressure without getting down on his knees, and take the reading off the gauge in a comfortable position. The correct pressures for various sizes of tires, as given by the tire manufacturers, are marked on the gauge, which is made by the United States Gauge Co., 67 Wall street, New York City.

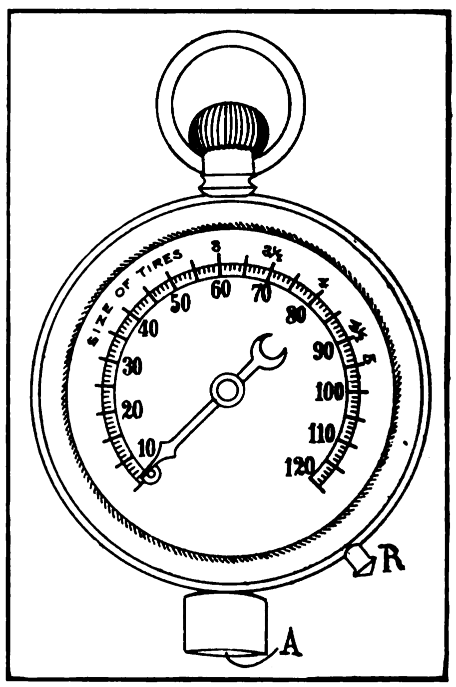

Fig. 3—Schubert tire gauge

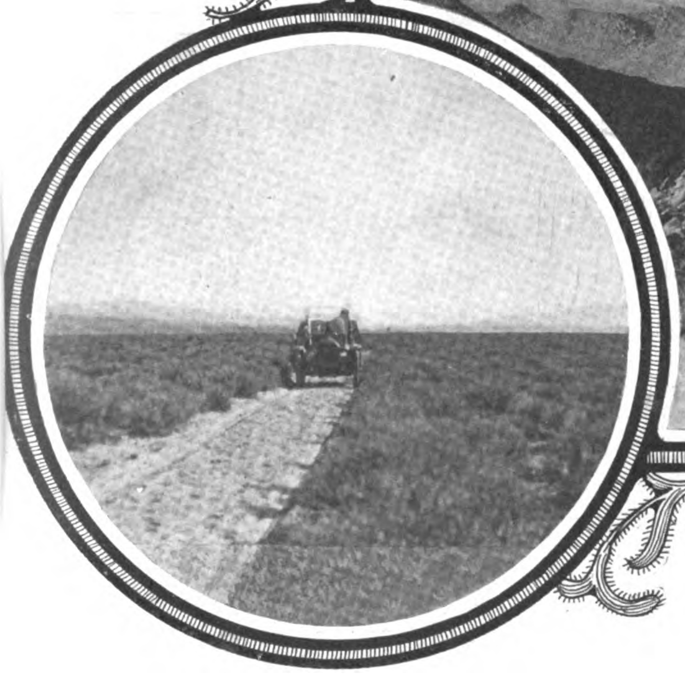
Vol. XXV New York—Thursday, December 21, 1911—Chicago No. 25

THE AUTOMOBILE

Across the Continent and Back

The Devil's Canyon in Southern California, to descend which was like going down Jacob's ladder



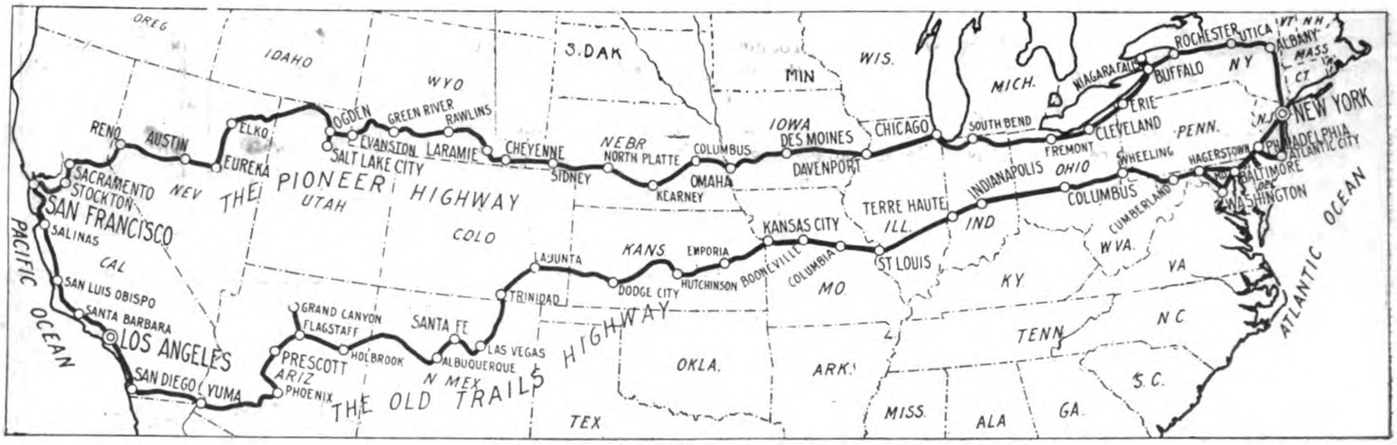
Volcanic ash road through the sage brush

AUTOMOBILE touring from coast to coast and back again will undoubtedly prove to be an important feature of motor car use. Trips from the Atlantic to the Pacific have been accomplished so frequently and with such a wide variety of cars that the general ability of all standard automobiles to negotiate the physical journey may be said to be firmly established.

The round trip is simply an extension of the one-way journey and is well within the strength and power of any good automobile.

The recent trip of Thomas W. Wilby, special agent of the Office of Public Roads, made under the auspices of the Touring Club of America from New York to San Francisco, Los Angeles and return, something like 11,000 miles, in an Ohio touring car, demonstrated among other things that such a trip does not involve any particular hardship. Mrs. Wilby, wife of the pilot, was a passenger throughout and finished the trip in perfect health. It required 105 days, or an average of about 105 miles for each day.

The car experienced no serious mechanical troubles and Mr. and Mrs. Wilby and driver, F. D. Clark, enjoyed the whole journey. Of course the trip was pioneering in a sense, as Mrs. Wilby is the first woman to accomplish the circuit. Some rough going was experienced; some discomfort was felt at the hotel accommodations in certain spots and there was more or less careful scheduling required in order to insure a plentiful supply of usable gasoline and oil. But these things were all exceptional, the general rule being simply to travel to the scheduled noon and night stops without making any special preparations and arrangements.



Map showing the route followed by the T. C. A. party in its double transcontinental trip

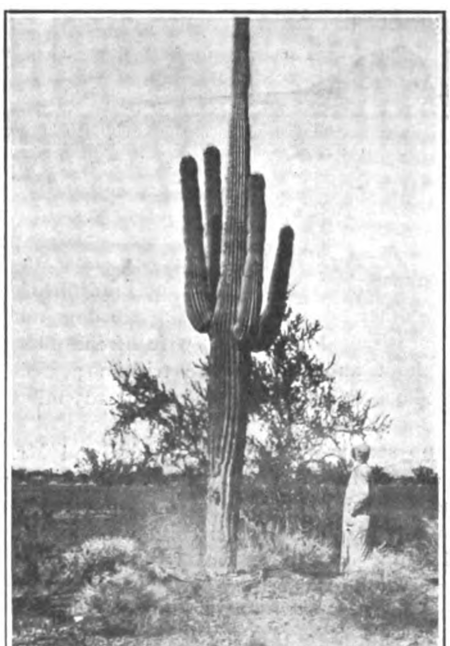
The average weekly expense for car and driver was $55 or 7 1-2 cents per wagon mile, which is considerably less than the average operative cost of automobiles.

The route traversed twenty states and touched the republic of Mexico at two points. Mr. Wilby made a special effort to include the show places of the continent in his itinerary and the route he logged will prove popular for tourists of the future who wish to take such a long trip.

The route may properly be divided into seven sections, as follows: First, from New York to Chicago; second, Chicago to Cheyenne; third, Cheyenne to San Francisco; fourth, San Francisco to Los Angeles; fifth, Los Angeles to La Junta; sixth, La Junta to St. Louis and seventh, St. Louis to New York.

Eventually such a tour can be made in 7 weeks, one for each section. At present there are two sections that require less than a week each to cover and at the present rate of road improvement two others will be passable in that period of time within a year. Another will probably be added within 2 years but the last two stretches, the big runs from Cheyenne to San Francisco and from Los Angeles to La Junta, will require longer to reach such a state of perfection.

Mr. Wilby's party was in no hurry. From one end of the route to the other a leisurely pace was maintained. The car was powerful enough to take advantage of good roads when they were met and so it did not have to be forced in the heavy spots. There was more or less social activity all along the route which required extra expenditure of time and the whole trip undoubtedly could have been made in 70 days if there had been any reason for so doing.



Giant cactus found plentifully in Arizona

However, speed on a transcontinental tour by automobile is out of place. The man who merely wants to get from New York to San Francisco in the least number of minutes possible will patronize railroads for many a year. It would please such a passenger if it were possible to make the journey in one night, or better yet, 1 hour. Scenery, enjoyment and pleasure have no part in such a journey and in an automobile tour from coast to coast and return, there should be nothing but enjoyment.

No matter how perfect the roads of the future may be, the round trip of the American continent should not include speed as its principal factor. The man who could boast of hitting 50 miles an hour in passing the Grand Canon of Colorado has no place in touring literature.

Taking the tour by stages as plotted by Mr. Wilby the conditions to be met are as follows:

The first section, extending from New York to Chicago, needs little notice. It can be done with ease in 5 running days, but should occupy at least 6 days. Starting from New York on a Monday morning in summer, the first day's run to Albany presents nothing but a pleasurable outlook. The roads are boulevarded all the way and first-class hotel accommodations for noon and night stops will be found.

From Albany to Buffalo, the route for the second day may be taken over roads that are almost as good as the foregoing. In Buffalo the hotels are first class.

The third day's run may be to Cleveland, skirting the south shore of Lake Erie. No difficulties will be found so far. There is some poor road included in the fourth day's run and it will probably be found to be advantageous to stop at Toledo for the night. From Toledo to South Bend, Ind., the road is fair to good, with a little poor going. From South Bend to Chicago is generally good.

No difficulties of any kind should be presented by this tour. Gasoline and oil of various kinds may be had every 20 miles if needed and from any point in the road a big city can be reached in an hour's traveling, where suitable accommodations can be had readily.

The second stage, from Chicago to Cheyenne, presents a wide variation from the first section, but imposes no hard obstacles. The first day's run may be to Davenport, Ia., on the Mississippi river. The Illinois roads are good in dry weather and passable in wet and there are numerous big cities between Chicago and Davenport that will afford everything necessary for the comfort of the tourists.

After crossing the Mississippi the way leads over the famous River to River road. This is a fine highway in dry weather, but all but impossible after a rain. The true significance of gumbo can be learned on the River to River road if there has been a wet spell just before starting from Davenport. Assuming that the sky is clear and there has been no heavy rain for a week, the trip to Des Moines, capital of Iowa, will be a pleasure.

Precisely the same conditions obtain for the run from Des Moines to Omaha that exist from Davenport to Des Moines. The road is better than Fifth avenue in dry weather and worse than the road from Natural Bridge to Roanoke, Va., after rain.

The Missouri River is crossed at Omaha and before the tourist stretches away the great plains where once roamed the buffalo, but which have now been converted into the granary of the nation. Up to a very recent date the roads through Nebraska have been unimproved and touring over them has been anything but a pleasure. There is little macadamizing to be found even now, but fully half of the distance from Omaha to North Platte has been graded and dragged. If the weather has been dry, or if the roads have had a chance to dry out for 24 hours before starting over them, there will be no particular trouble to be found. From this point west mileages, however, will have to be cut down sharply.

It will be well to try to go no further than Columbus on the first day out from Omaha. The roads are not bad, particularly in dry weather, although after a protracted drought there will be much dust. The next day's trip should be to Kearney and the next to North Platte. The character of the country has changed radically from what was found further east. The tourist is on the edge of the dry country. From Kearney west the dry, rolling hills are covered with sage brush where they have not fallen under the hand of the agriculturalist.

Only 30 years ago this whole country west of the Missouri river was deemed to be fit for a cattle range only. Gradually the desert limits have been pushed back and to-day heavy crops of grain are raised without irrigation clear to the Wyoming line. But here and there the tourist may still see a vast sweep of sage covered hills, extending to the horizon. The air is dry and clear, and touring, if done without too much effort at speed, will be found to be delightful.

But upon leaving North Platte it will be just as well to arrange for supplies of gasoline and oil at various intervals beyond Cheyenne. At Laramie, Rawlins, Green River and Evanston such supplies can be had, but if it is not possible to order fuel and oil to be delivered along the route at convenient intervals provision for an emergency supply to be carried in the car itself should be made. It is not a pleasant thing to think about running short of fuel, water or oil on a lonely desert or mountain trail, far from human habitation. It is much better to carry an extra supply, even though arrangements can be made to get supplies along the way.

Sidney is a town of comfortable size and should be the first night stop beyond North Platte. The run from there to Cheyenne is rather long, but the road is well marked and presents no particular difficulties.

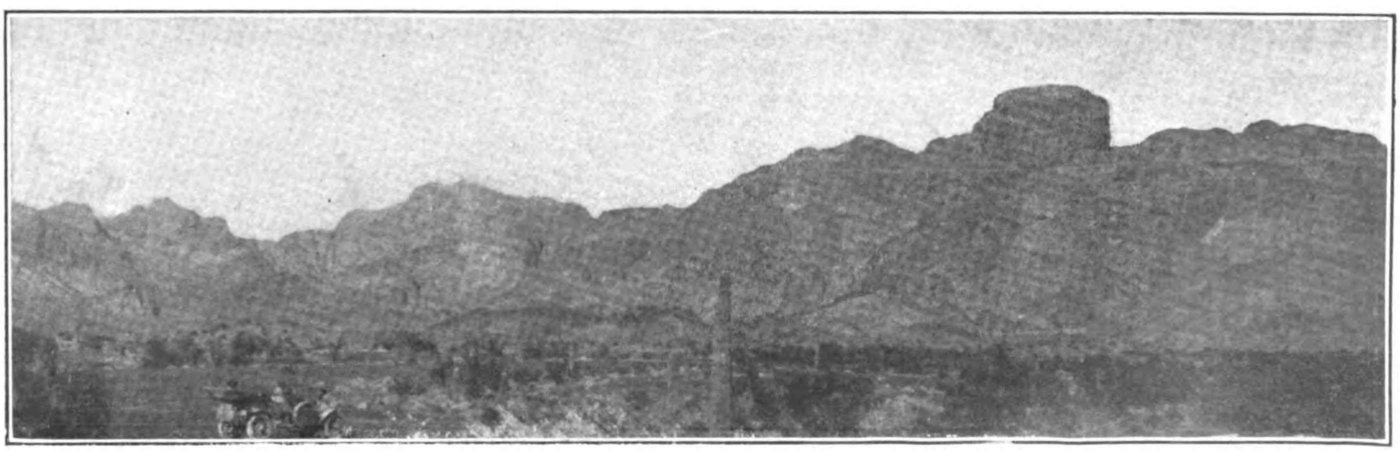
Cheyenne is pretty well up in the Rocky Mountains and from there to the Utah state line the tourist would better make haste slowly. While the distances between considerable towns is not great, it is quite certain that the breaking of an axle 20 miles from one of them would prove serious enough. The answer is to drive slowly and carefully, avoiding irrigation ditches and using much judgment in crossing what are known as dry washes and high centers. The first step across Wyoming is from Cheyenne to Laramie. This is a stiff clmb to the level of the high plateau, across which the Union Pacific tracks traverse the backbone of the continent. The road surface is not bad practically all the way to Laramie and the tourists will pass the Sherman monument, marking the highest point on the continental divide, before reaching Laramie. This is 8,010 feet above sea level. Medicine Bow, a small place with a good hotel and where necessary supplies of fuel and oil may be obtained is far enough away from Laramie to make a good mid-day stop and from there to Rawlins, 57 miles, the road tranverses a wild country where ranch houses are few and precautions as to fuel should be taken. The route is some distance from the railroad.

Beautiful natural road through Dog Valley

At Rawlins all necessities and many comforts are available. The main hotel is comfortable and there are several garages and supply depots.

There is a good road out of Rawlins as far as Wamsetter, where the trail enters the Bitter Creek country. Desolate solitude about describes the aspect of nature through this stretch of the way and it is not much improved in crossing the Red Desert, which has been described as the worst link in the continental chain of highways. This road however, is not superlatively bad. It is much more easily traveled than would be the River to River road in Iowa after a hard rain. It is rough and difficult, but in any long tour worse roads will be found in spots. Rock Springs, a small railroad town, affords about the only chance for a night stop in this territory. The accommodations are not what may be termed luxurious.

From Rock Springs to Green River the road is excellent and noon stop may be made at Green River. Granger lies a short distance beyond. This place is known as the gateway, from a railroad viewpoint, to the whole intermountain region. West from Granger the old road, used by former tourists, may be



A typical panorama encountered by the Wilbys in their journey through the Great Southwest

Lava-strewn mountains in Arizona through which the travelers progressed at a snail's pace

abandoned and striking off to the south a better road will be found that is fully 30 miles shorter to Evanston. This passes through Lyman and Bridger, prosperous farming communities, where smart efforts at road improvement have been made. The road out of Bridger is not well posted and much care should be exercised to get on the right road. Within the past few weeks this section has been posted so that mistakes in future need not be numerous. The last 20 miles into Evanston is over excellent road.

Gasoline is scarce in this country but may be had. Provisions for oil are necessary. Evanston has everything necessary in the way of supplies and accommodations, but not many luxuries.

The next day's run is short, only 86 miles to Ogden, Utah, but it is one of the most delightful trips possible to modern motoring. The way leads through a series of small fertile valleys, well watered and productive under the hands of the Mormons. The road is fine and the scenery, particularly after reaching Weber canyon and Devil's Slide, is gorgeous in the extreme.

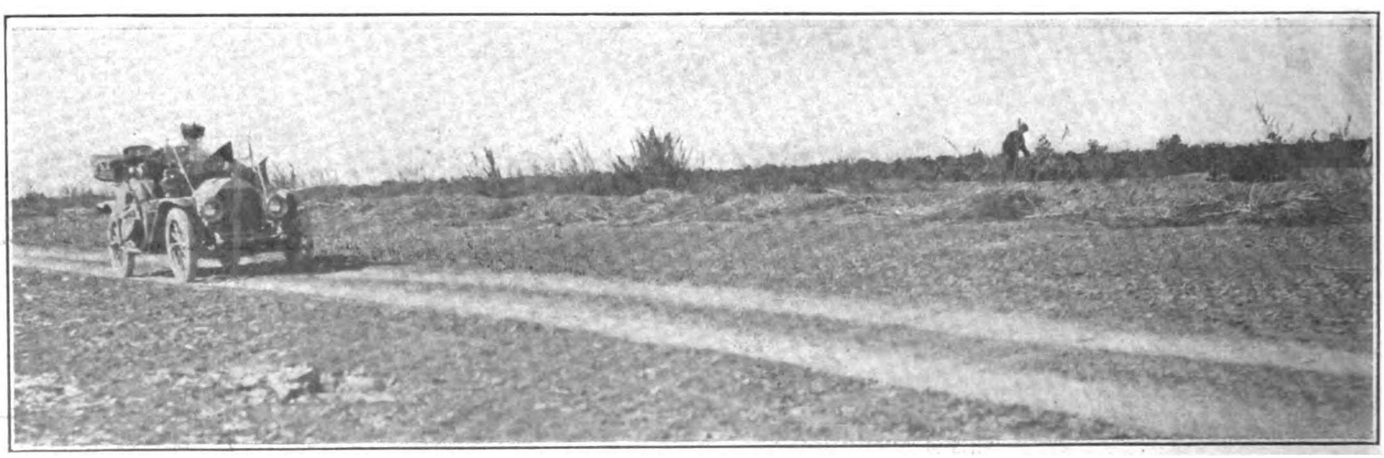
Ogden affords practically everything the tourist could find in an eastern city, including excellent hotels. If desired, the tourist may run down to Salt Lake City and, after spending as much time as he wishes in sightseeing, can run back to Ogden to resume his westward way.

This may be a day or a week, for the Mormon capital is a fertile field for the tenderfoot tourist. Park City and its silver mines and the various wonders of the region may be inspected with pleasure and profit. Salt Lake is only 35 miles south from Ogden and the roads are fine, but rather dusty.

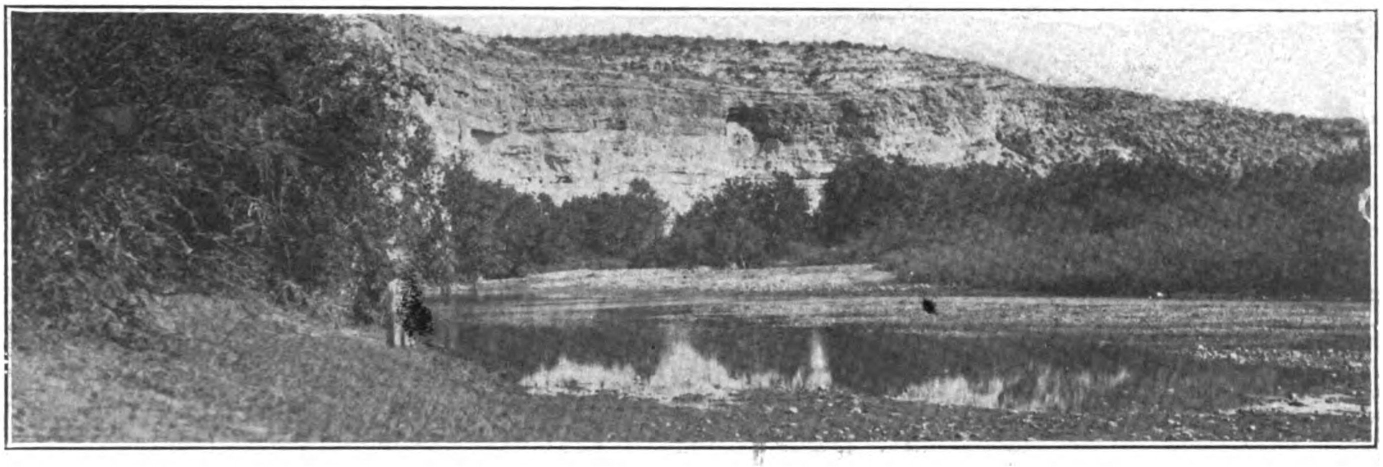
West from Ogden the road lies through an absolute desert. There are hundreds of miles of alkali flats that are as forbidding and austere as a New England old maid. After rounding the Great Salt Lake to Lucin, the trail strikes southwestwardly to Montello and Elko, Nevada. The roads are good all through this section and passing south through the Diamond Valley to Eureka. There is much wonderful scenery in this valley, the desert scheme of coloration appealing with much strength to eastern visitors. Turning west at Eureka the road strikes across the desert toward Reno, passing Austin and Fallon. The tourist should arrange a sliding schedule across the desert west of Ogden. Extra supplies of water should be carried in the car and a fuel and oil schedule ought to be made in advance. The towns are infrequent, but a night schedule can be arranged that will not necessitate any camping out. Eureka is 106 miles from Elko, mostly over good gravel roads. The little city has a good hotel and offers an opportunity to get fuel and oil. Eastgate should be the next night stop, 130 miles west of Eureka. A ranch house is about the best that it can offer in the way of hotel accommodations and care should be taken to secure a supply of fuel. The run into Reno is through much the same kind of territory. At Reno there will be no trouble about accommodations and supplies.

The climbing of the Sierra Nevadas to Truckee presents quite a problem for any kind of transportation. The roads are not bad, but the grades are terrific and entirely impassable after a snowstorm. Such storms, however, are not frequent except for about 6 weeks in the dead of winter, when no sane human being would want to go mountain climbing. From Truckee to Sacramento the way is sharply down-grade, winding in and out among the mountain peaks of the great coast range. On the down turn the road passes through the section where gold was first discovered in California and leads by easy stages to San Francisco via Stockton and Oakland.

An extra week ought to be put in by the tourist in examining Nevada with its marvelous mines and wonderful color plans, but a week more can be spent enjoyably in the Sierras and 2 weeks is not too long to enjoy San Francisco after the long trip.



Through the cotton fields of Southern California, where the roads were generally excellent



Montezuma's Castle is a huge cliff dwelling in the limestone bluffs north of Prescott, Arizona.

The fourth stage of the great round trip extends to Los Angeles. The Californians declare that the route is perfect, but the eastern tourist will find that it is not. Except for considerable macadamizing near San Francisco and Los Angeles the road is rough and dusty except during the rainy season and deep and muddy during the rainy season.

Los Angeles is one of the garden spots of the world and is deserving of an extended visit. It has the largest number of automobiles per capita of any large city in the world and its roads are wonderfully perfect, particularly in the territory immediately adjacent to the city.

On the eastward way the tourist must take his own time. There is something interesting in almost every mile and haste will serve to spoil many a memory that otherwise would prove a pleasant possession. And there is another excellent reason for moving deliberately, for the roads are very rough and heavy in long stretches.

It is just a nice easy run from Los Angeles to San Diego and the roads are good all the way. Then the course turns east and passes Campo, the Devil's canon, Imperial and El Centro. The roads are very narrow and winding and the scenery is sublime. After El Centro the way leads out upon the floor of the desert. Following this there is a space of 60 miles of exceedingly rough going, the trail crossing the international line into Mexico and returning at Aldrado. From there to Yuma, Ariz., the road is a severe trial. After leaving Yuma the first big obstacle to be passed is the ford of the Gila river. For a considerable period of each year this stream is too shallow to ferry and too deep to ford. Provision for a team of mules to pull one's car through this stream should be made. From the east bank of the river into Buckeye the road is indescribably rough and 10 miles an hour is a perilous rate of speed. But from there to Phoenix the roads are fair to good. A side trip to the Grand Canon should be made from Flagstaff before taking up the tour again. The roads from Phoenix to Prescott are fair to excellent and from Prescott to Flagstaff poor to fair.

Arizona presents a virgin field for the tourist. There is something wonderful to be seen every hour in the day, the enchanted, petrified forests and real forests; the fields of green grain and the spectacular cactus, combined with the sweep of the desert and the grim strength and ruggedness of the mountains.

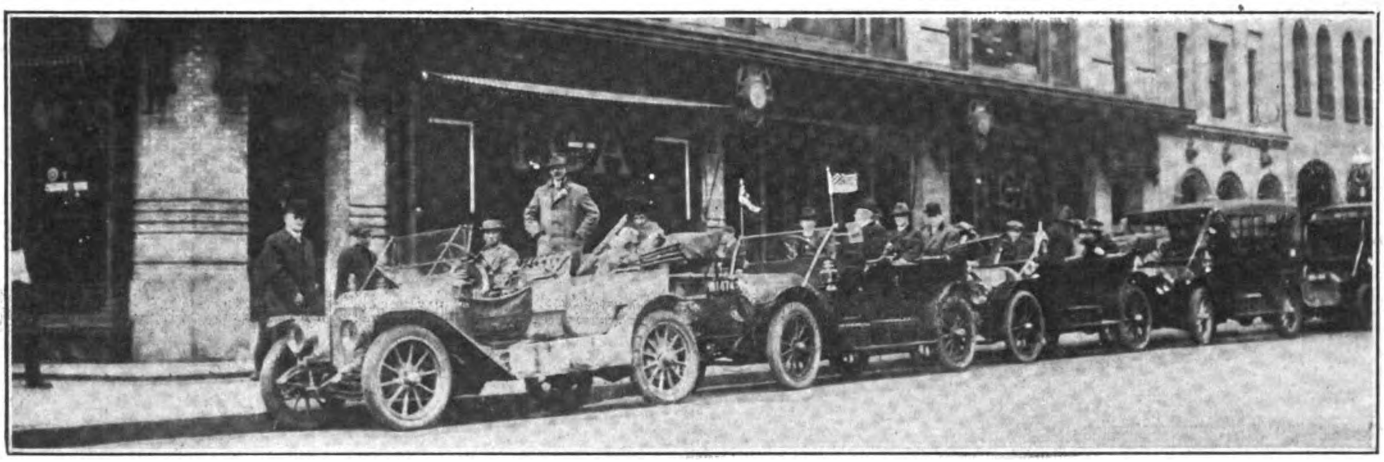
The route passes through Holbrook and continues to the New Mexican line without radical change in topographical characteristics. Albuquerque, the ancient capital, is the first New Mexican city of size to be encountered. Then come Santa Fe and Las Vegas in the Raton Mountains. The Raton (pronounced Ratoon) Pass, across the summit of the Rocky Mountains, is the last bit of major mountain-climbing on the route. The country is practically flat at Trinidad, Colo., and thence out on the dry plains to La Junta (pronounced La Hoonta), where the fifth stage of the journey ends.

From La Junta to St. Louis is a very easy run compared with what has gone before. There are no hills to climb of any great size and the Kansas roads are fair to good generally. If it is wet, however, the going will not be enjoyed and if it is very dry there will be much dust. In Missouri the roads are deep in spots and rough in others, but much road improvement is being made in that state.

The chief cities touched by the return route are: Dodge City, Hutchinson (the salt center), Emporia, Kansas City, Booneville, Columbia and St. Louis. East from St. Louis the way leads through Illinois to Terre Haute, Ind., Indianapolis, Columbus, O., Wheeling, West Va., Cumberland, Md., Hagerstown, Washington, Baltimore, Philadelphia, New York.

The direct route, without side trips of any kind, measures about 8,500 miles. The side trips have a mileage of 1,500. Mr.

Donner Lake, California, a beautiful spot where many tragedies were enacted in the pioneer days



Arrival of the Wilbys in the OhiO Mudhen with their escort at the headquarters of the Touring Club of America

Wilby's party covered 1,000 miles more than this, but it is a matter of individual taste as to whether this additional mileage should be included.

The late summer is an ideal time to start such a tour and the northerly route followed on the way west will do much to temper summer heat. Then, by the time the party has reached Los Angeles, the season will be so far advanced that the southern route returning will prove more agreeable than the one through the northern mountain passes.

Mr. Wilby states that no special equipment is necessary for this long tour, but in his notes he calls attention to the fact that the car was furnished with a heavy tarpaulin or oil-cloth cover for use in heavy rain or hail.

There is no necessity of carrying a camping outfit unless the taste of the party is in that direction, for some sort of accommodations can be found at each night stop. Once in Nevada and twice in the southern desert the party had to sleep in ranch houses and the hotels could not be termed luxurious outside of California west of the Missouri river. Here and there is to be found an excellent hostelry in the intermountain region, but the general run is not like the eastern or California hotel.

Good, warm clothing and complete waterproofs are essential to health and comfort on such a trip, but care should be taken not to clutter up the car with a lot of unnecessary baggage. Every extra pound counts on a short tour and on one including 10,000 miles one extra suit case weighing 50 pounds may mean the difference between comfort and misery from one end of the ride to the other. Only such baggage should be carried as may be packed securely in a canvas cover and strapped behind the car. A hand bag in the tonneau is an abomination. It either crowds the back seat or hampers the foot room. On a short trip such an inconvenience is trifling, but on one that is long it is about as trying as could be.

Another bad effect of extra and unnecessary baggage is its destructive tendency as far as tires are concerned. At normal load and inflation tires are made to deliver a minimum mileage by their manufacturers. If 50 pounds is carried over the normal load the tires are surely going to suffer.

Arrangement can be made before starting to have laundry work done at various points en route. If an emergency camping outfit is carried it should contain absolutely nothing that can be left behind. A portable alcohol lamp, a silk dog-tent and a single pot and pan. The robes of the car can be used as bedding in a pinch. Emergency rations, ready packed, will furnish enough food to keep soul and body together until some haven of refuge can be reached. The whole outfit should not weigh over 25 pounds.

Gasoline can be had all along the route at convenient intervals, but in some sections it is much scarcer than in others. In price it ranges from 11 1-2 cents to 50 cents a gallon. The latter price obtains where there is the least supply. On this trip the point where gasoline is highest is between the large towns of Arizona and to a degree in Wyoming and Nevada. At Omaha the tourists will do well to buy three cans for emergency use. One should carry gasoline, another oil and the third water. They may not be used at all, but in case of need they will prove to be wonderfully welcome. It is possible to strap these cans on the running boards and in the tonneau, so that they will not crowd the passengers.

Within the next year or two many automobile parties will make this trip, and as each successive car passes over the route it will be found that road conditions will show improvement. The whole country is alive to the need of good roads and the mere plotting of such a double transcontinental tour will undoubtedly lead to considerable immediate interest in this route. It should be understood that the mountain passes in Wyoming and at Truckee are impassable for automobiles in winter and that the Yuma desert, Arizona and New Mexico are not pleasant touring grounds in July and August. And, on the other hand, the trip across the plains is not pleasant in wet weather and early spring touring is not pure joy in the east. Therefore such a trip as Mr. Wilby made should be undertaken systematically and with due care to avoid the unpleasant features noted above. May would be a fine time to start, but August would be better, particularly if the tour is to be leisurely, as it should be to properly enjoy the beauty of the scenery along the route.

Maryland Motorists Must Go for Tags

Baltimore, Md., Dec. 18—Judge Gorter, in an opinion which he handed down in the Superior Court, held that the State Motor Vehicle Law does not require the Commissioner of Motor Vehicles to deliver license tags to the homes of owners of cars. The question raised was whether the law required the Commissioner of Motor Vehicles to deliver the metal plates or markers which the law required to be attached to motor cars to the owners' homes, the complainant in the case being William B. Littleton, of Hagerstown, Md.

Road Experts Meet in New Hampshire

Concord, N. H., Dec. 18—The first good roads convention ever held in New Hampshire—and the second ever held in New England, the first being at Boston three years ago—ended its deliberations to-day after being in session two days, during which time about 300 men prominent in highway maintenance work had a chance to exchange ideas on the subject.

Governor Robert P. Bass was instrumental in bringing the convention here and he had Federal and New England officials as guests to give an outline of what New Hampshire needed.

Industrial News by Mail and Wire

DAYTON, O., Dec. 18—The first annual Speedwell truck convention, just held at the factory, was a success from every standpoint. The agents received much valuable information from Mr. R. Harry Croniger, who has charge of the truck end of the Speedwell business. The burden of his instructions was: First, in showing truck prospects how methods of handling goods may be re-adjusted, and second, demonstrating the economy of the truck and then giving a conservative and liberal estimate of the probable operating costs and if trucks are installed to co-operate in educating drivers and mechanics to give the trucks the sort of attention and consideration which will produce greatest efficiency.

Those of the agency force present were: B. A. Jackson, New Orleans; Frank A. Groves, Chicago; H. D. Hudson, Minneapolis; P. D. Karshner, Kansas City; L. V. Lynch, San Francisco; George L. Baker, Dayton; Paul C. Curtis, Boston; G. B. Garrison, Chicago; A. J. Sanderson, Buffalo; C. A. Nation, Portland, Ore.; John Cunningham, Rochester; W. L. Hicks, Nashville; N. J. Adams, Troy, N. Y.; Eugene Hanking, Jacksonville, Fla.; E. A. Shanks, Louisville; George Turner, Pensacola, Fla.; J. B. Hastings, Montgomery, Ala.; W. P. Peterman, Franklin, La.; J. A. Kays, Meridian, Miss.; Mitchell Nash, Waco, Tex.; Will Spring, Houston, Tex.; Walter C. Martin, New York; H. H. Hawkins, Los Angeles; E. B. Jenkins, Pittsburgh, and Lloyd Richards, Mobile, Ala.

To Double Output of Grinnell Electrics

DETROIT, Dec. 16—At a meeting of the Grinnell Electric Automobile Co. to-day the directors decided to double the output for the coming year, enter the wholesale field and begin an extensive advertising campaign. Henry Goodman, of New York, was present, and a contract was closed with him to represent the company in the East.

About three weeks ago the company, which formerly was the Phipps-Grinnell Electric Auto Co., was reorganized, C. A. Grinnell and I. W. Grinnell, of the firm of Grinnell Brothers, the largest piano house in Michigan, purchasing the stock of Joel G. Phipps, giving them a majority of the holdings.

New Company to Handle Imported Cars

Three veterans of the automobile business have formed a new company, with headquarters in New York, to handle several makes of imported cars. These are Paul Lacroix, Harry U. Kibbe and Stefan G. Kjeldsen, and they are organized under the firm name of the Paul Lacroix Automobile Co.

The new company has the exclusive agency in this country for the English Daimler, Clement-Bayard, Itala and Zedel, and will also sell Renault and Panhard cars. The Zedel, which is new to America, is a small car. The new company will exhibit at the Importers' Automobile Salon, showing its different makes with bodies by Demarest.

Ford Co. Cuts Giant Melon

DETROIT, MICH., Dec. 18—While the motor car concerns are not disposed to tip off their plans in advance, it is said that several of them have arranged to remember their employees in one way or another, while there are rumors of a number of large-sized dividend distributions. The Ford Motor Co., it is learned on good authority, recently distributed $1,000,000 among its stockholders, Henry Ford receiving a little less than 60 per cent., and no doubt some handsome bonuses will be forthcoming if the sales department makes good on its estimate of 75,000 cars for the 1912 season.

Motorette May Be Reorganized

HARTFORD, CONN., Dec. 18—Although no official announcement to the effect has been made, it is understood on excellent authority that an effort will be made to reorganize the C. W. Kelsey Manufacturing Company, of this city, manufacturers of the Motorette and that the new company will continue to make the three-wheel motorcars.

The Motorette Company was formed last fall to manufacture a three-wheeler at Hartford, C. W. Kelsey, formerly of the Maxwell-Briscoe Company, being at its head. It was backed with Philadelphia capital. It has been in difficulties several times during the past year and its present trouble is the cumulative result of a number of similar crises. Formal action was commenced at Hartford on December 6.

Universal Truck Co. Reported Sold

DETROIT, MICH., Dec. 19—The Universal Motor Truck Co. has been sold to Howard W. Walton, of New York, according to announcement this afternoon. The corporation is capitalized at $350,000. Among those who are reported to have sold their holdings to Mr. Walton are the following: C. H. Haberkorn, C. B. Culbertson, August Kling, A. E. Barker, George Uhlein and Louis Camper.

U. S. Motors Netted $2,040,256

Stockholders of the United States Motor Co. held their annual meeting Tuesday and elected J. W. Stoddard to succeed H. J. Edwards on the board of directors. The annual report of the company showed a net profit up to the end of the fiscal year of $2,040,256 and after dividends, interest and depreciation had been deducted it left a net surplus of $453,748.

There has been a marked advance in United States Motor stock on the Detroit exchange the past few days. Common has jumped from 13 to 20 and preferred from 55 to 62, with the upward tendency apparently unchecked.

Lozier to Put Out Big Truck

DETROIT, MICH., Dec. 18—It is reported that the Lozier Motor Co. is preparing to put a high-power truck on the market in the near future, and may have it ready for exhibition at the Detroit show along with several other cars. The company's engineering department has given the truck question a good deal of careful study and several new ideas will be incorporated in the forthcoming truck, it is understood.

Hupp Announces New Touring Car

DETROIT, MIH., Dec. 18—R. C. Hupp has announced four self-starter models of the new R-C-H car, including a five-passenger touring car, a two-passenger roadster, a touring roadster and a Colonial coupé. All are equipped with dual ignition, demountable and quick detachable rims, 32 x 3 1-2 inch tires, Prestolite tank, extra rim, top, side curtains and all the rest. Mr. Hupp plans to display his full line at the Detroit show.

The Legal Field—Spark Plug Suits

SPARK PLUGS next will be the focus of interest in the automobile world. The whole matter of their legal status is about to be threshed out before the United States court in New York when the legality of the Mosler patent is put to the affirmative test, probably at the February term.

A. R. Mosler & Company have commenced actions against the Auto Supply Company, John Lurie, president, involving alleged infringement of the patent owned by the Mosler company on the part of the Metzger, Rogers, Belgian, Rajah and American Coil Company spark plugs. Suit has also been brought against the Emil Grossman Company, the Champion Spark Plug Company and the Jeffrey & DeWitt Company in the Federal courts at and near Detroit and a similar action has been entered against the Motor Car Equipment Company.

The suits are all similar and the complaint alleges infringement of the Canfield patent No. 612,701, now owned by the Mosler company, covering the two claims following: "In a gas, oil or vapor engine igniter or sparker a recess or counterbore around the electrode or electrodes, above the sparking point or points when said electrodes are used vertically, for the purpose of preventing an injurious accumulation of the products of combustion or other foul matter on the insulation of said electrodes."

The second claim is for a recess or counterbore of such depth and size as to form space for an air cushion and prevent the circulation of the explosive mixture into such counterbore.

The *prima facie* proof has been made and practically all the testimony in the most advanced cases has been taken before the commissioner, and Judge William A. Redding for the Mosler company, believes the cases will be ready for adjudication before the end of the year. Under fair circumstances a final decree of the court of last resort can be had within the next year.

The history of the patent has a tinge of romance connected with it. It was issued to Frank W. Canfield, of Manistee, Mich. (now dead), October 18, 1898, and consequently has nearly 4 years to run. On the recommendation of Mr. Redding it was purchased for a substantial sum by the patent association affiliated with the A. L. A. M. During several years it lay dormant in the treasury of the association while the attention of the automobile world was centered on the Selden litigation. But about 2 1-2 years ago, Mr. Redding advised the Mosler company to purchase the patent and that action was taken. Under the terms of purchase the right was given to each member of the A. L. A. M. at that time to manufacture plugs under this patent for its own product, without royalty. The Mosler company issued a license or two to other manufacturers and the present suits are the result of its efforts to assert its exclusive rights to the device covered by the Canfield patent. The complaint asks for injunction, accounting and damages, amounting in the aggregate to about $1,000,000. The deposition of Prof. Carpenter, of Cornell University will be taken in support of the Mosler claim.

New Patent Laws May Affect Industry

WASHINGTON, D. C., Dec. 16—Never before in the history of patent legislation have bills and proposed legislation been introduced in Congress of more vital importance than during the present session. The newly introduced bills, numbering nineteen in all, cover patent matters of deep interest to the motor car industry. One of the patent bills now pending proposes compulsory license. Under its terms the owner of a patent is put in a peculiar situation. If another inventor wishes to use it for an improvement on an invention he has only to apply to the Commissioner of Patents and get a right to use the patent upon terms without any notice or hearing. Another drastic bill provides that a patent granted upon an improvement on a machine, etc., previously patented shall expire at the same time as the original patent. The other bills are equally drastic.

It is known that influences are at work in Congress to secure, if possible, a radical change in the patent laws, and the introduction of these bills is the first step in that direction. According to noted patent attorneys these bills, if passed, will effect such a complete revolution in the American patent laws that various industries will be stunned by the differences in their legal rights under the existing and under the proposed laws.

Klaxon Fails to Restrain Newtone

United States Judge Thomas I. Chatfield has denied the motion of the Lovell-McConnell Mfg. Company, makers of the Klaxon horn, for a preliminary injunction against the Automobile Supply Mfg. Company, makers of the Newtone horn, and has decreed that all questions of alleged infringement and other defenses shall be reserved for final hearing. The court also prohibits both litigants from making or circulating statements likely to hamper the court in coming to a prompt decision.

The Newtone party is specifically prohibited from circulating the literature known as The Truth and The Facts in the Case, and the complainants are barred from bringing actions apparently based only on the hope of intimidating customers of the defendants.

The case will probably be heard in April, 1912.

The decision is as follows:

"This cause coming on to be heard on Sept. 25, 26 and 27, upon complainant's motion for preliminary injunction under the patents number 923,048, 923,049, 923,122, granted to Miller, Reese, Hutchison, on May 25, 1909: On complainants' motion to enjoin the publication by defendants of a certain circular entitled (The Truth), or (The Facts in The Case); and further on defendant's motion to prevent further prosecution of a number of pending actions and the bringing of any additional actions against defendant's dealers and any intimidation of defendant customers and the trade generally; and on reading and considering on behalf of the complainants twenty-four affidavits, with exhibits therein identified, and after hearing George C. Dean, and T. J. Johnston, of counsel for complainants and C. A. L. Massie, and Ralph L. Scott, of counsel for the defendants, both orally and by briefs, and the court being fully advised in the premises. and having under date of Nov. 20, 1911, handed down a written opinion—now, on motion of C. A. L. Massie., solicitor and of counsel for defendants, it is this day ordered that complainant's motion for preliminary injunction under the three patents aforesaid, be and the same is hereby denied and all questions as to alleged infringement and other defenses are reserved for final hearing.

"And it is further ordered, that in order to prevent a recurrence similar to those relating to the matters of advertising and threatened suits, the complainants and the defendants be and they hereby are enjoined from any act or proceeding which will embarrass or prevent this court in bringing this suit to a prompt and complete determination upon the merits. That any suit brought by complainants under the patents aforesaid, based upon the existence or use or sale of defendant's said Newtone horns, and in which the issue shall be dependent upon the same conclusion as the issues herein, shall not be carried beyond the point of serving process. And that this injunction includes such institution or prosecution or litigation in other districts as will apparently be for the purpose of intimidation or punitive effect alone. And it is further ordered that the defendants and their agents and attorneys be and they hereby are enjoined from circulating, in the same or similar form, the contents of the circular known as (The Truth) or (The Facts in The Case), set forth in complainant's papers, and both parties, their agents and attorneys are enjoined from attempting to present to the public and to their customers their views as to the meaning and effect of the evidence already presented, or as to what it may have shown in the present action (but counsel may explain the same to persons entitled to the information), in order that, whichever party shall ultimately prevail, the trial of this action will not be affected thereby in matters to which the decree of the court cannot effectively reach.

"And that in view of the previous disputes arising herein, the defendants be and hereby are enjoined from making to the public or the trade or to any jobber, dealer, or purchaser of warning signals, either verbally or in writing, in the same or similar form, any statement such as made in the exhibit letter regarding preliminary injunction, the patents in suit, the question of infringement or complainant's course with regard to the same. And that the complainants be and are hereby enjoined from making or circulating any of the statements heretofore restrained by this court. (Signed) THOMAS I. CHATFIELD,
United States Judge."

A.L.A.M. Patents to Undergo Court Test

Proceedings in the suit against the Palmer & Singer Mfg. Co. were brought to public notice during the past week by the sending of more notices on behalf of the plaintiff in the case, warning of alleged infringement of the Dyer patents.

The suit is in the United States District Court, Southern District of New York, and has been pending for some time. The Dyer patents include one covering an H-slot guide plate for the controlling lever; a gearing for automobiles; a slide gear; unit power plant and a planetary gear device.

The A. L. A. M. was interested in the patents and was empowered under its rights to give shop licenses to any of its members. The Palmer & Singer Co., while a licensee of the A. L. A. M., never applied for such shop license, according to officials of that organization.

Dyer is proceeding to stop the alleged infringement of his patents and to collect damages for such infringement. The case may be reached during the coming term of court.

Electric Storage Battery Company Wins

Denying a motion for a rehearing, the United States Circuit Court of Appeals has settled finally the preliminary stage of the battle that has been waged for several years by the Gould Storage Battery Company and the Electric Storage Battery Company, in which the former sought to force the latter to convey to it the Madden patent owned by the Electric Storage Battery Company. The court below decided against the Gould company and the upper court sustained the decision.

The present status of the litigation is that the Gould company is suing the Electric company in the New Jersey federal court and the Electric company is suing the Gould company in the western district of New York. Both suits allege infringements.

The Madden patents are two in number. The first of these, 570,244, was granted October 27, 1896, covering a machine for transforming, reducing and preparing lead blanks for storage battery requirements and to produce grids of various sizes and kinds. The second patent is No. 572,363, for a machine to make grids with shelves or partitions which have uniform molecular density. This patent was issued December 1, 1896. The first is owned by the Electric company and the second by the Gould company.

The court in deciding the matter at issue concludes with the following paragraph: "This unfortunate controversy could have been avoided had the inventor been less disingenuous and had the parties observed with greater care some of the principles of the Decalogue. Neither party is blameless, but we are unable to say that the proof preponderates so strongly in favor of the complainant as to justify us in granting the extraordinary relief demanded. The decree is affirmed with costs."

Auto Lighter Sues on Patents

Suits have been filed in the United States Circuit Court by the Auto Lighter & Equipment Co. of Massachusetts against the Inst Lighter Co. of Ohio and the Oldsmobile Co. of Massachusetts for alleged infringement of United States letters patents 953,985 and 962,113.

The Motor Specialties Co. of Boston, manufacturers of the Flash auto lighter and licensee under these patents, also appears as complainant in the above suits.

It is claimed that these patents broadly cover a safe and positive system of automatic acetylene gas ignition, particularly in the fact that the igniting spark precedes the gas at the headlights.

Another feature claimed under these patents is a single operating handle for controlling both the gas and the electric spark to light or extinguish the lights with one movement, which handle locks in on or off positions.

Weed Chain Gets Six More Injunctions

The past week has been lively for the Weed Chain Co. in the courts. Preliminary injunctions have been granted on behalf of the company against three concerns within the jurisdiction of the United States courts in the eastern division of northern Ohio as follows: The Studebaker Automobile Co., M. and M. Co., and Dorsey D. Foote. This action is similar to numerous others taken by the Weed concern to enforce its patent rights.

In the United States Circuit Court in New York orders were signed to extend the time for taking testimony in the actions of the Weed company against Edmond, Wooster and Newhall. These suits are like the others in general scope.

Word comes from Detroit that on Tuesday last, Judge Angell, on complaint of the Weed company, authorized a preliminary injunction against the Perry Chain Grip Company, the Union Steel Screen Company and The Motor Specialty Company, restraining them from placing the "Weeder" auto chain grip on the market. The action is based on an alleged infringement of the Parsons patent by the manufacturers of the "Weeder" chain. This the defendants admitted, but counsel declared the patent would be proved invalid on facts not presented in the Snyder case. An injunction was also sought to enjoin the Perry grip, but the court declared this would have to be taken up later.

Victor Creditors to Get Xmas Present

As a kind of Christmas present to the creditors of the Victor Auto Supply Manufacturing Co. an initial dividend amounting to 2 per cent. of the approved claims has been declared by the United States District Court officials in bankruptcy.

The dividend will be payable December 28. The dates of subsequent payments in this estate and their amount will be determined later.

Zust Debts May Be Compounded

Walter E. Coe has been named receiver for the Zust Sales Co., of New York, the concern handling the product of the Zust factory in this section. An effort is being made to effect a composition of the matter and the prospects for such an outcome are said to be excellent.

The assets and liabilities are unofficially declared to be about $35,000 each.

Rules for the French Grand Prix

IN the following translation of the official regulations relating to the Grand Prix and Coupe de l'Auto races to be held in June, 1912, under the auspices of the Automobile Club de France, the French wording has been followed as literally as practicable and without close adherence to the terminology currently adopted in this country, the object being to render faithfully, for the information of all American manufacturers, drivers and general readers, not only the general trend of the regulations but also particularly those provisions which seem to open loopholes for unexpected interpretations or which contain mandatory injunctions of an unusual nature.

Official Regulations for the Grand Prix of the Automobile Club de France, June, 1912, and for the Coupe de l'Auto

1—The Automobile Club de France organizes for 1912 an international race reserved for constructors defined under section 4 and entitled the Grand Prix de l'Automobile Club de France.

2—In this trial shall be incorporated the "Coupe de L'Auto" for the vehicles conforming to the formula for the "Course de Voitures Légères, 1911," as given in section 13. These vehicles shall at the same time participate in the general classification.

3—A prize of 20,000 francs shall be awarded to the constructor of the vehicle arriving first under the general classification. A prize of 10,000 francs shall be awarded to the constructor who has the team securing the best position with a minimum of three vehicles finishing.

4—As constructor is considered one who has manufactured both the motor and the transmission.

5—The race will take place during the second half of June and will comprise two consecutive days at the rate of 800 to 1000 kilometers per day. The date and place will be decided later.

6—*Entries:* Each constructor has the right to enter 4 vehicles with the option of taking part at once in both trials, it being understood, however, that the total cannot exceed four.

7—Constructors employing motors or mechanisms built under the same license, or under a title into which the same name enters, cannot together engage more than four vehicles.

This rule applies without regard to nationality and whether the license is granted by a foreign constructor or vice versa.

In case of disagreement among firms manufacturing vehicles under the same license, the Sport Commission will decide the number of vehicles to which each firm shall be entitled, basing its decision on the importance of each firm as evidenced by the number of vehicles it has delivered to the public during the past three years; and, whatever the number of constructors involved, no exception will be made from the second paragraph of this section.

8—Entrance fees are: Fifteen hundred francs for one vehicle, 2,750 francs for two, 3,750 francs for three, and 4,500 francs for four. The nominations must be submitted at the office of the Sport Commission of the Automobile Club de France at No. 8 Place de la Concorde, and the list will be closed on December 30, 1911, at 6 o'clock evening. The entries will not be definitely accepted unless at that time the number of vehicles nominated reaches a minimum of thirty. If this quorum were reached December 30, entries at double fees could be validly submitted to the Sport Committee until March 1, 1912, at 6 o'clock evening.

9—The entrance fees cannot in any case be refunded and will remain as acquired for the race fund, excepting the case provided for in the third clause of the preceding section.

10—Entries will be recognized as valid only if accompanied by the fees as provided in section 8 and contingently upon acceptation by the Sport Committee.

11—If the number of entries should be judged too great, for reasons of safety, the Sport Committee reserves the right to reduce it, by selection, drawing lots, eliminatory trial or any other means at its option.

12—General Conditions: The Grand Prix is open to all vehicles without other limitations than those resulting from the provisos of section 18.

13—The vehicles taking part in the "Coupe de L'Auto" must satisfy the following conditions:

(1) Must be equipped with a motor of at least four cylinders, whose total cylinder volume does not exceed three litres, and in which the ratio of stroke to bore cannot be higher than two or smaller than one. The constructor must thus keep within these limits, no tolerance being allowed.

(2) Must weight at least 800 kilograms. This minimum weight is to be understood as follows: The weight of the vehicle with two-seated body, without water, oil, gasoline (essence), tools, spare parts. (Emptying of the crankcase and gear cases will not be required.)

14—The Sport Committee reserves the right, at the beginning of the race, to take all necessary measures for the verification of the sealing of pieces done by it.

15—All attempt at fraud on the part of a contestant will involve the exclusion from the race of the vehicle, and may, according to the circumstances, involve the disqualification of the driver, his mechanic, of the constructor interested and of other vehicles entered by the latter.

The constructor will have to pay a fine of 10,000 francs, and the Sport Committee will decide the duration of the disqualifications incurred.

16—All vehicles will carry, obligatorily and as a maximum, two occupants side by side, of a mean minimum weight of 60 kilograms for each, it being understood that where this mean weight is not reached the surplus must be supplemented by ballast.

17—The contestants will not be permitted to take part, unless on the day of weighing-in they are provided with the document issued by the Ingenieur des Mines, attesting that the vehicles entered by them satisfy the legal requirements.

18—All vehicles entered must have:

(1) A reverse gear actuated by the motor.

(2) An exhaust pointing horizontally rearward and sufficiently high to avoid stirring up dust.

(3) No vehicle broader than 1.75 meter can take part in the race.

19—The vehicles taking part in the race must, according to the nationality which they represent, be painted in the following colors:

Germany, white; America, white and blue; England, green; Belgium, yellow; Spain, yellow and red; France, blue; Italy, red; Switzerland, red and white.

20—*Weighing-in.*—A regulation concerning especially the operations of weighing-in will be published later. Its provisions will be made known betimes to those interested.

21—*Repairs and replenishments.*—Repairs and in general every other operation must be made exclusively by the crew of the vehicle.

Use of the removable or dismountable rim and of the dismountable wheel is permitted.

Replenishments—oil, fuel, pneumatic tires and spare parts—can be taken on board only at one or two places of the course, designated in advance, and every infraction of this rule will involve the exclusion of the vehicle from the race.

The exclusion from the race will also be applied to every vehicle departing voluntarily from the course.

Each firm will have the right to a section, drawn by lot, at the replenishment station or stations.

22—Firms which are not competing, but, nevertheless, interested in the race and desirous of occupying a section at the replenishment stations must pay a fee of 1,000 francs.

Requests for these sections must be accompanied by the fee mentioned and will be received by the Sport Committee of the Automobile Club de France until December 30, 1911, 6 o'clock evening. Such requests at double fee will be received until March 1, 1912, 6 o'clock evening.

23—*Drivers.*—The drivers and mechanics of each vehicle may be changed during the race, but only at the end of each lap and under the surveillance of a commissary.

The reserve drivers must be designated before the race to the Sport Committee.

The mechanic may replace the driver at any spot of the course, but only in case of duress (fatigue, accident, etc.).

24—The Sport Committee reserves the right to exclude any driver for reasons bearing upon the security of the public or of other contestants.

As soon as the constructors shall have engaged drivers for their vehicles it shall be their duty to make them known to the Sport Committee by registered letter, accompanied with an agreement of the following form:

Between the undersigned, Mr. X, constructor of automobiles, and Mr. Y it has been agreed as follows:

Mr. Y agrees to drive in the Grand Prix of the Automobile Club de France in 1912 a vehicle of the make X.

Mr. X, constructor of automobiles, binds himself to furnish, for this race, to Mr. Y a vehicle of the make X.

Signed X and Y.

By this arrangement, the driver will not be able to drive a vehicle of another make, unless the two parties agree to rescind their contract, and, in that case, the Sport Committee must be kept advised of the change.

25—The driver and mechanic of each vehicle entered must possess certificates of competence to drive automobiles.

26—*Starts.*—The order of starting in the race shall be decided by drawing lots.

The hour for starting the first vehicle on the first day and the intervals between starts will be determined later.

On the second day, the vehicles shall start in the order of their arrival and with intervals to be decided upon later.

The time for closing the race (on the first and second days) will be decided by prefectorial decree.

Under all circumstances the commissaries of the race shall have the right to stop the vehicles before the hour fixed.

27—*Parking.*—Every vehicle having finished the course of the first day within the prescribed time limits will be placed immediately thereafter under the orders of a commissary charged with watching it and conducting it in the park.

After the motor is stopped, the driver is permitted only to close the fuel and oil valves, if need be, and the vehicle will be parked by hand power.

Each vehicle will be placed in a separate compartment and nobody will be permitted to approach it before the hour for starting on the following day.

On the morning of the second day, the vehicles will be placed in the hands of their respective crews at the moment of departure for each of them.

No operation bearing upon the start of the motor, on replenishment of supplies, on repairs, etc., can take place till after the signal for starting shall have been given, and the time used for this purpose shall be counted as running time.

28—*Protests.*—Every protest must be made in writing and placed in the hands of one of the commissaries of the race during the hour following the closing of the control stations.

Every protest, in order to receive consideration, must be accompanied by the sum of 100 francs, which will not be refunded to the claimant unless his protest is recognized as well founded.

29—The contestants agree, in case of dispute, to recognize only the jurisdiction of the Sport Committee and in no case to have recourse to the courts.

30—*Responsibilities.*—Civil and criminal responsibilities of all sorts are borne by the contestants to whom they relate.

31—*Insurance.*—It shall be the duty of all constructors engaged in the race to provide for insurance against accidents of all sorts to third parties, which may be caused during the race, and also against fire, covering direct damages as well as all recourse action relating to merchandise, fuel and material deposited at their replenishment section.

To this end, it shall be the duty of constructors to mail to the Sport Committee by registered letter and one month in advance of the date of the contest, duplicate of the policies which they have signed.

On the day of the race the Sport Committee would refuse to start any contestant having failed to comply with this requirement.

32—*Application of the Rules.*—By the fact of his entry, the contestant agrees to conform to the provisions of these regulations and the decisions of the Sport Committee.

33—All points not provided for in the present regulations will be decided according to the general racing regulations of the Automobile Club de France.

34—The Sport Committee of the Automobile Club de France remains sovereign judge of the application of the present regulations and reserves the right to modify them as event may dictate.

Boycott for 1912 French Grand Prix

Immediately after the official publication of the regulations which the Sport Committee of the Automobile Club de France had adopted for the Grand Prix and Coupe de l'Auto races in June, 1912, a despatch from Vienna announced to the astonished leaders of the once powerful club that their kind invitation to the automobile industries of other countries, once more to come and cross arms with the industry of France on French soil, had not met with the glad and eager response which was accorded to similar invitations in former years, before the foremost French houses concluded to stand pat on their dignity and refrain from racing. The despatch stated briefly that a number of German manufacturers had signed an agreement to boycott the French Grand Prix race.

Inquiries made by wire in Berlin brought only confirmation of the news. The Benz, Mercedes, Adler, N. A. G., Opel, Protos, Dürkopp and Bergmann firms had all signed a contract binding each and all to permit none of the cars of these makes to take any part in the French Grand Prix race of 1912, and in the nature of things the boycott included the Coupe de l'Auto race to be run in conjunction with the Grand Prix under a separate classification. Moreover, the Belgian firm La Metallurgique, it was found, had made common cause with the Germans.

The Fiat concern of Italy, on the other hand, had refused to sign any pact, either to participate or not to participate, but at the last account had sent no entries to the Sport Committee in Paris.

Protest Against Fairmount Race

PHILADELPHIA, Dec. 14—Emphatically protesting against the granting of further authority to hold the annual Fairmount Park road race and questioning the jurisdiction of the Fairmount Park Commissioners to furnish a permit, Dr. J. William White, a member, reintroduced a lengthy resolution to abolish the event.

That the event was dangerous to the lives of both participants and spectators; was but a scheme of manufacturers, serving no good end, in that racing had no value in the development and improvement of motor cars; that the example set by racing drivers tearing off 90 miles an hour was likely to have a detrimental effect on weak, ill-balanced persons by creating a desire to emulate the speed kings; that only remarkably good fortune had so far prevented tragedies in the Park and that the chief element of interest in it is the always-present chance of accident—these are but a few of the many objections enumerated.

Admitting his personal enjoyment of these races, Dr. White said that his pleasure was marred because "by reason partly of my vote in this commission, an uncertain number of persons (among them women and children), who were by our act encouraged to be present, might be instantly killed during one of these races, and because no conceivable precaution could eliminate this possibility.

"The fact that in our races the altogether admirable management, the fine work of the police and of the Park Guards, and the amenability of the spectators to discipline, combined with good luck, have hitherto enabled us to escape without serious accident does not invalidate or even weaken this argument. There can be no possible assurance that this good fortune will continue.

"Before I introduced this resolution I made an effort to ascertain the state of intelligent opinion on the subject; I submitted the matter to the members of a literary club, to the board of a financial institution, to a large committee made up of medical men and to a number of individuals, some of whom were connected very closely with automobile affairs. Nine-tenths of those to whom I spoke owned cars. They were asked in each case whether or not, if they had the authority and the responsibility of the Park Commission, they would or would not support the resolution. Those who said they would not were in a numerically negligible minority of not more than 2 per cent. A well-known member of the Bar, Mr. George P. Rich, is of the opinion that we have no legal right to permit these races, that an injunction against them would hold, and that in case of damage to person or property we would be legally liable."

As to minor matters, such as injury to Park roads, turf and shrubbery, no complaint is made because "the benefits of a day's outing to the owners of the Park—the people themselves—would more than compensate for this disadvantage, especially as the roads are put in order again by the promoters of the race."

"Inquiry has led me to believe that the races have little or no value as tests of automobiles," says the doctor, "that they chiefly subserve the interests of a small minority of manufacturers; that there are other and harmless ways of trying out engines and tires, and running or steering gear; and that even races may be held—but not on public roads—with far less danger to participants and none to spectators. I am also strongly inclined to think that these particular races involve a disregard of the rights of some of our citizens who will, I know, in the future, ask the courts to protect them."

The resolution has been referred to the Committee on Superintendence and Police for report. In the meantime Dr. White's broadside is met by the convincing arguments that in the four races so far held here under the auspices of the Quaker City Motor Club and the municipal authorities not an accident of any kind to spectator or driver has occurred; that the Park course has been proven safe; that the annual turnout demonstrates its popularity; that the statement that persons are attracted by the element of danger is not borne out by the facts, and that Dr. White's suggestion of a municipal race track is not feasible and couldn't begin to compensate for the attraction of a race in the picturesque and easily-accessible Park.

1912 Racing Season Promises Activity

NEW YORK, Dec. 14—At a meeting to-day of the contest board of the American Automobile Association it was decided to send out letters to all of the clubs and promoting organizations throughout the country, asking them to select dates for their coming contests for the 1912 season, with the object of enabling the board at its next meeting to issue the first draft of the 1912 calendar. Already Indianapolis has asked for Decoration Day and Labor Day for speedway races; Philadelphia has put in a bid for the second Saturday in October for the Fairmount Park 200-mile road race; application has been received from California for a date about the middle of May for the Santa Monica races, and a request has come from Chicago asking for dates in August for the Elgin races. From present indications it would seem that 1912 will be an active one in the road-racing field.

Several drivers came under the ban of the board for participation in unsanctioned events. T. S. Duby was suspended as a driver for two years for competing at De Witt, Iowa, September 15, under the assumed name of Bliss at an unsanctioned meet. C. B. Kent was given six months' suspension for competition at an unsanctioned meet at Madison, Wis., September 24. Application from the New York Motor Club for reinstatement by the board was received but no action was taken. This club was suspended for conducting an unsanctioned meet on July 4.

The board received from the Manufacturers' Association a number of recommendations for changes in the 1912 rules. The different members of the board have suggested many alterations and it is expected that the final draft of rules governing 1912 contests will be completed during the New York show season.

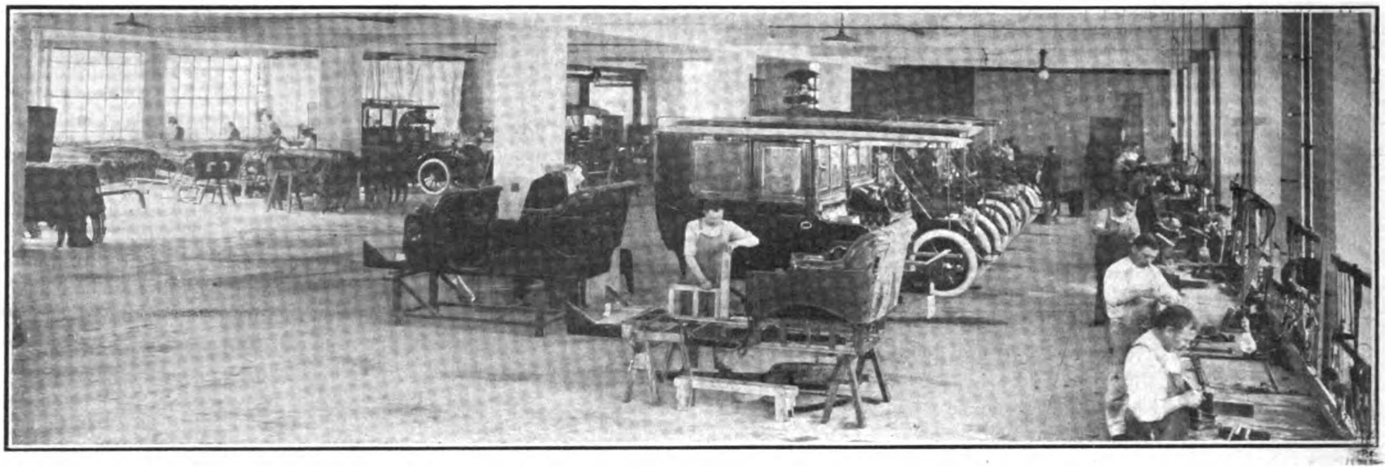


Fig. 1—A portion of the coach department in the new Packard service station in Long Island City

What Makers Are Doing for Buyers

As Illustrated by New York Packard Service System

AT the junction of Thompson avenue and VanDamm street in Long Island City, the Packard Motor Car Company, of New York, completed in October, 1910, the pioneer service station in the metropolitan district—that is, speaking of service as a feature distinct from all other branches of the automobile business and as entitled to a home of its own.

This location was chosen with great foresight. The building faces Diagonal street viaduct over the Sunnyside yards of the Pennsylvania Railroad, the air-line from Queensboro Bridge Plaza to Thompson avenue, which is the main artery for automobile traffic from Manhattan to all points on Long Island. Being thus situated, it cannot escape the observation of the great army of Long Island commuters who daily pass through the busy railroad yards.

Fig. 2—Exterior view of the building, showing the modern tile and glass construction

The distance of the service station from the company's main office in New York City is 3 miles, an easy 15-minute run by automobile. A delivery service is operated between the two points, carrying passengers, stock, inter-department communications and the like, on a regular schedule of five round trips a day. Telephone tie lines weld the two offices almost into a unit and provide immediate communication on all subjects of mutual importance—a big factor in service efficiency.

The building is thoroughly modern in every respect. It is approximately 150 feet long by 100 feet wide and is constructed of steel, hollow tile, concrete and glass, there being about 24,000 feet of the

Fig. 3—A portion of the body painting department on the fifth floor. Job costs for this department are made up at the right

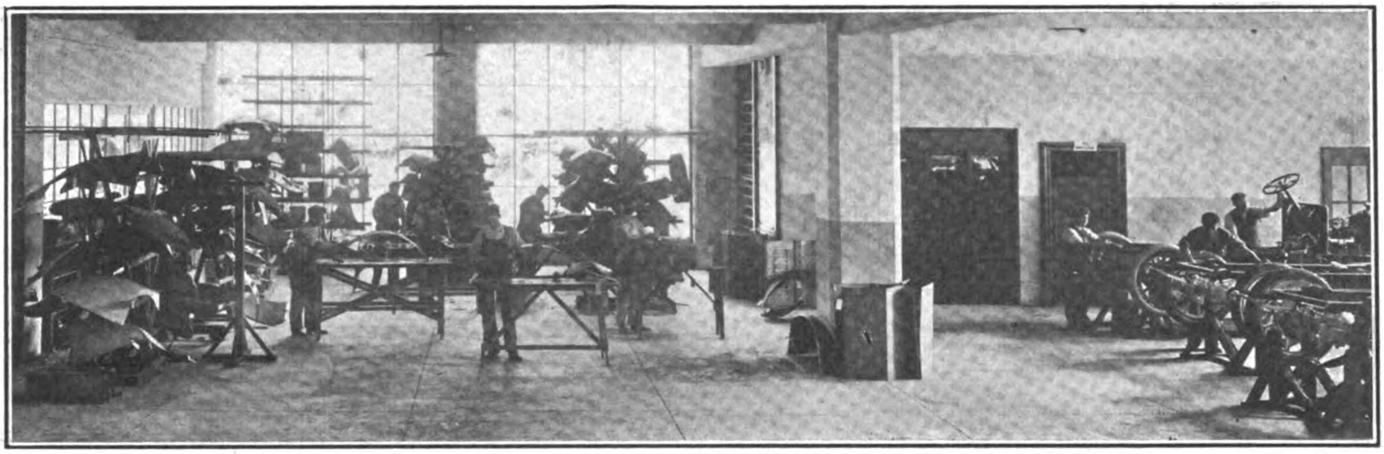

Fig. 4—A corner of the paint-shop is given up exclusively to fender painting. Note the drying racks

last-named material. Eight floors and a basement make up an available floor space of about 200,000 square feet. Some idea of the size of the plant may be gained from the fact that there is room for about 200 cars and 35 trucks in simultaneous process of repair, together with 45 cars and 100 car bodies in dead storage.

Special Features of the Building

Despite the fact that the building is of rigid fireproof construction throughout, there is a most elaborate sprinkler system. A roof tank stores continually 40,000 gallons of water for sprinkler service, and in the basement is a reserve tank containing 75,000 gallons more. These two tanks are inter-connected, and in case of fire, a powerful pump will raise the basement supply into the tank on the roof.

Gasoline is stored in underground tanks outside. These tanks are four in number, of 500 gallons capacity each, connected with pumps located in a small, fireproof outhouse. Oils, kerosene and turpentine are kept in the basement in 150-gallon tanks, the delivery pumps being on the first floor.

Besides the passenger elevator at the east end of the building, there are two freight lifts in the southwest corner. The latter are 12 feet by 17 feet, with capacities of 8,000 pounds and 15,000 pounds, respectively. These do all the heavy lifting, trucks being carried on the 15,000-pound elevator, while pleasure cars and freight are raised on the one of less capacity.

How the Space Is Utilized

It is interesting to note the way in which the large amount of space in this new service station has been used. The eighth or top floor is devoted entirely to truck repairs, and has a capacity of 35 vehicles. It was chosen for this purpose because only a single row of pillars was required to support the roof, leaving a clear space on the north side approximately 66 feet by 150 feet in which to manœuver the bulky commercial cars. The overhead clearance is 15 feet, which is needed to accommodate the taller truck bodies. Like the other floors, it has three full sides of glass, but it differs from them in that it also has a skylight, making an exceedingly well-lighted workroom.

The seventh floor is given over to car repairs, with room for thirty-five machines. On the north side, where the light is best, is the "motor line," or series of horses to hold complete motors during the process of overhauling. Cranes are used to lift the motors from the car frames to the horses. Back of the latter stand the dismantled chassis. Here clutch, transmission and miscellaneous work is carried on.

On the south side are placed the cars which need only slight repair, and here the radiator repair men also work, the few machine tools required being located next to the south windows.

The coach department makes use of the fifth and sixth floors for woodworking, carpenter work, chassis painting and lumber storage. Forty cars can be accommodated on the fifth floor, while the sixth has room for forty-five. At the west ends of both of these floors will be found two banks of lockers in which is stored customers' property removed from cars in process of repair. The office of the coach department is at the east end of the fifth floor, and in it are made up the job costs for this class of work in a manner identical with that employed by the repair department. Along the north side of this floor are the assemblers, while the trimmers occupy the south side.

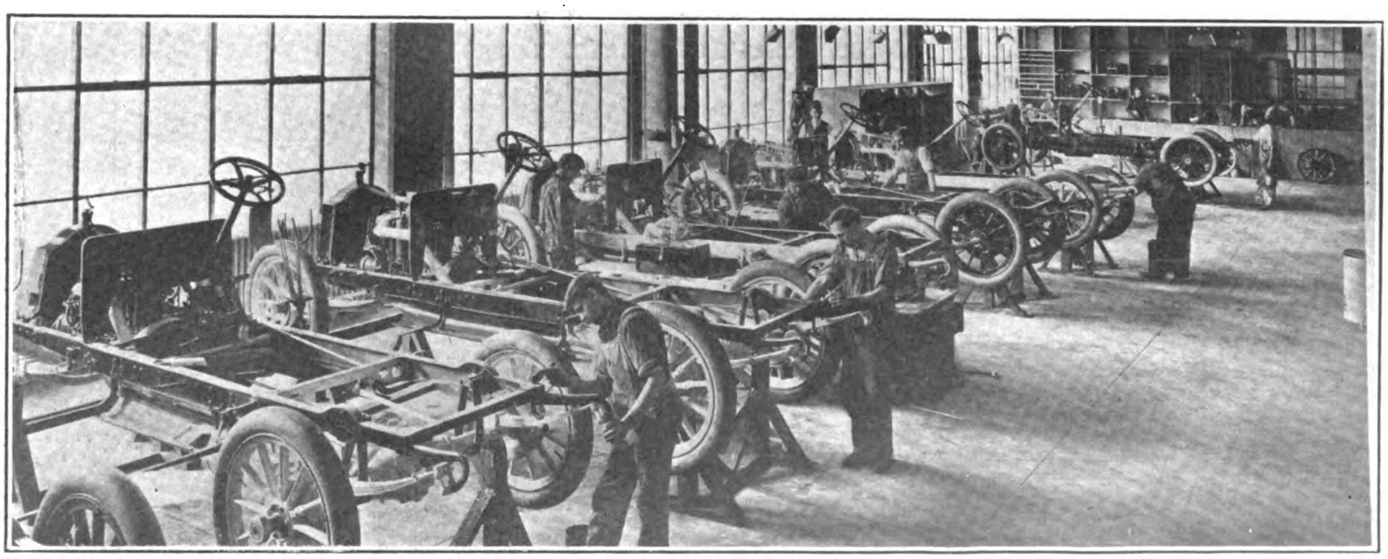

Fig. 5—Chassis painting section. Each group of painters devotes its time to work on one particular part of the Packard machine

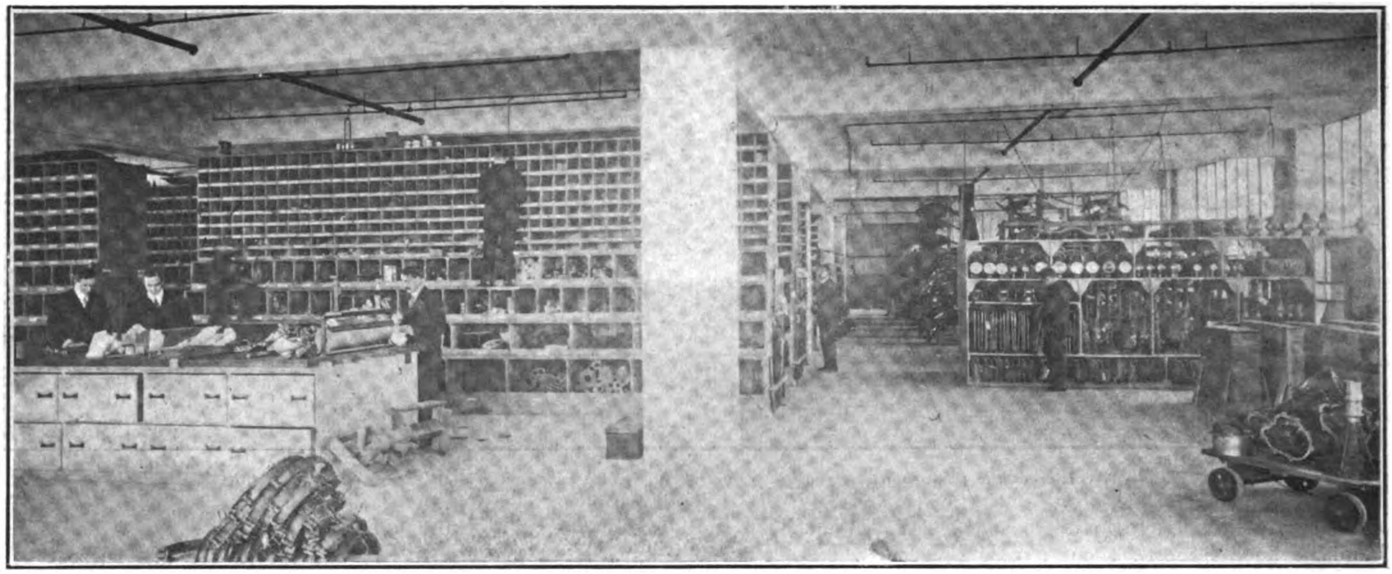

Fig. 6—The stockroom occupies the entire second floor. In it are kept parts for every model since 1904

Painting is done on the fourth floor, which has a capacity of thirty-five cars. Bodies chiefly are painted here, though chassis that cannot be accommodated on the sixth floor are taken care of. Along the north wall at the east end, where it gets light on two sides, is the varnish room, in which the finishing coats are applied under dustless conditions and at uniform temperature. The frame workers, whose work is devoted exclusively to windshields and limousine window frames, and the paint mixers are within an inclosure on the south side next the freight elevator.

The third floor is devoted to dead storage, there being room here for forty-five cars and 100 bodies, as already stated. Along the east, north and south sides are racks of special construction, providing for two tiers of bodies, either open or closed. Cars are stored in the center of the floor and are arranged with a view to convenience in the matter of shifting.

The entire second floor is given over to the stockroom. Within an inclosure of some 13,000 square feet is stored the supply of parts and accessories necessary to provide for the Packard owners throughout a wide range of territory. At the east end of the inclosure is the customers' window and at the west end of the floor, outside, is the receiving and shipping department, to which all incoming shipments are delivered, and from which all outgoing orders are sent.

Forty-five cars can be accommodated on the first floor, which is used for quick service, storage of finished machines awaiting delivery and the like. At the east end is located the superintendent's office, with accommodations for stenographers, telephone operator, checkers, etc. The south side is taken up by four vehicle entrance doors, one to each freight elevator and one at either end of the floor proper.

The Packard Service Methods

A description of the Packard service methods must begin with the stockroom. For service efficiency a stockroom must have an adequate supply of all parts and accessories for which instant demands occur.

This Packard stockroom must provide for the needs of its two fellow service departments, the repair shop and coach department, for customers' direct orders, for stock orders from the New York stockroom and for the branches at Newark, N. J., Hartford, Conn., and Springfield, Mass. In a word, it is the central distributing point of the New York company.

The orders of the repair shop and coach department are presented in the form of requisitions chargeable to repair orders in hand as hereafter described. They come in duplicate by way of a dumbwaiter running between the floors. One man is

Fig. 7—The pleasure car repair shop. Men working on the motor are stationed nearest the windows to get the benefit of all the light possible

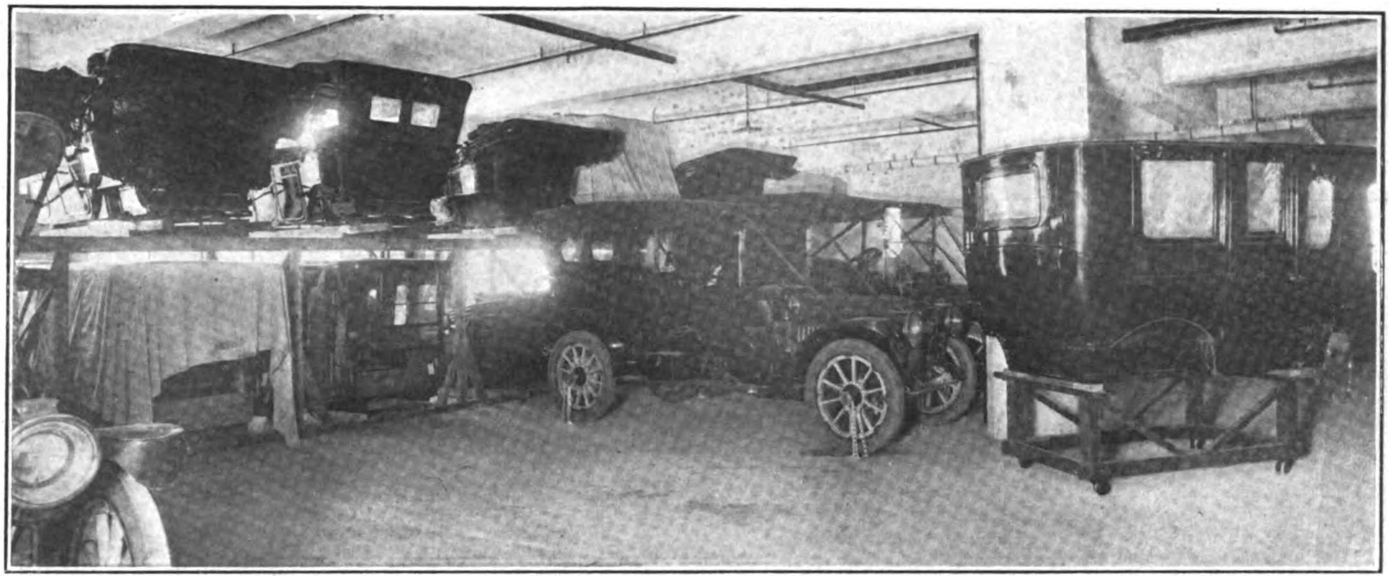

Fig. 8—View in the dead storage department. Racks are provided for the storage of two tiers of bodies, as shown

delegated to receive them and follow them through for quick delivery. It is his duty to act as personal representative for the other two departments, and if there are delays or errors in filling requisitions, he is the responsible party. He rarely fills requisitions himself, but stays at his post to receive them, to hasten the men who do fill them and to check the filled orders for accuracy. His location is such, in relation to the customers' window, that he can serve it after the same fashion.

Customers' and branch orders are handled after much the same methods as those employed by any well regulated plant. A record of each order of any sort is made on a perpetual inventory, which is charged with all stock received, credited with all delivered and posted with the date and quantity of every order. It is subdivided according to models and each part of every year's car has its danger limit. The interchangeability of parts, which is a feature of the company's construction policy, tremendously reduces the number of individual entries in the record, but it nevertheless entails an immense amount of work.

When the order calls for work that will detain the car for from two days to several weeks, the check includes everything in detail and a copy is sent to the customer with a request to report promptly any shortages noted. When the order calls for short jobs only, the check includes merely the readily removable equipment. Copies of all complete checks are interchanged between the New York office and the service station. Discrepancies at either point are immediately investigated.

Cars come from the New York office accompanied by orders and checking sheets, all of these typewritten with four copies. The repair shop receives one, the coach department two and the head tester, who is also finished inspector, one. Frequently the attention of but one department is required, but it is necessary for each to have its own record of the order, as either department may be called upon for work by a supplementary order.

After being "checked in," each car is sent to the floor where work on it is to begin. Cars to be stripped or relieved of light equipment are handled first by the assemblers, who remove whatever is to be locked up for protection and place it in the lockers already mentioned. The car is then delivered to either the repair or coach department according to the nature of the work which is to be performed.

It is seen that the Packard Company has worked out its system well, such exhaustive methods being necessary on account of the volume of its business. In an ordinary month there are approximately 400 cars and trucks which apply at the plant for repair of one form or another, and the company's aim is to meet this demand for its service in as satisfactory a way as possible.

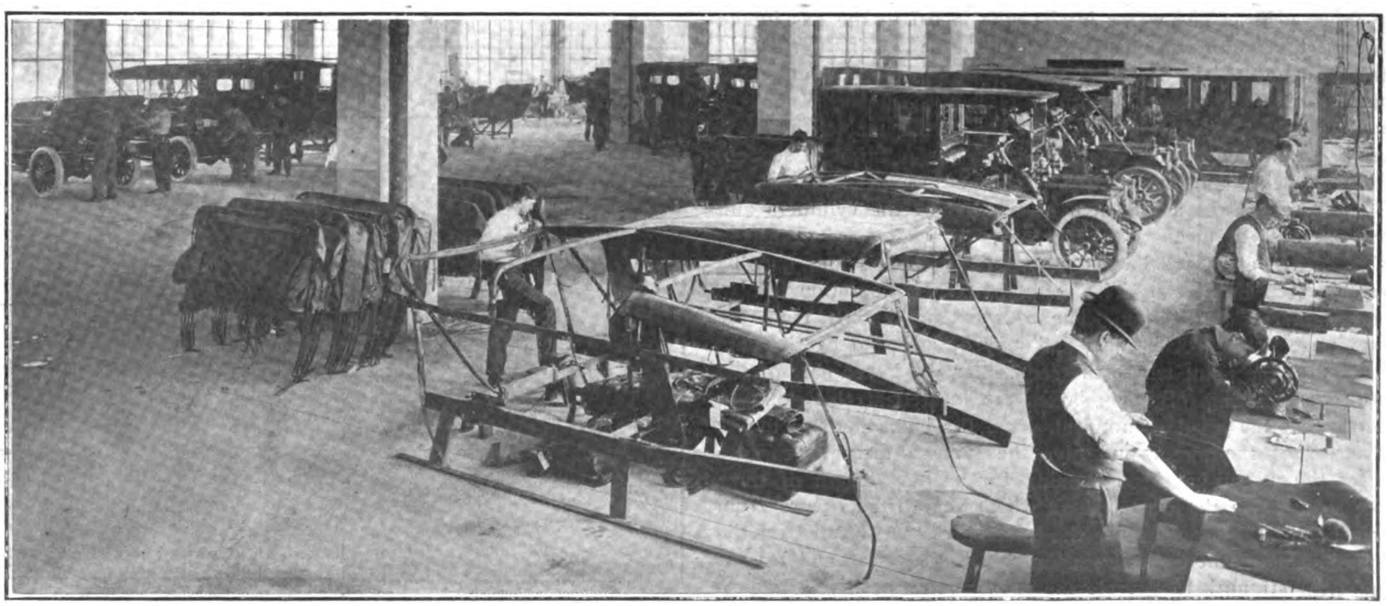

Fig. 9—A large section of the coach department is devoted to upholstering and top making

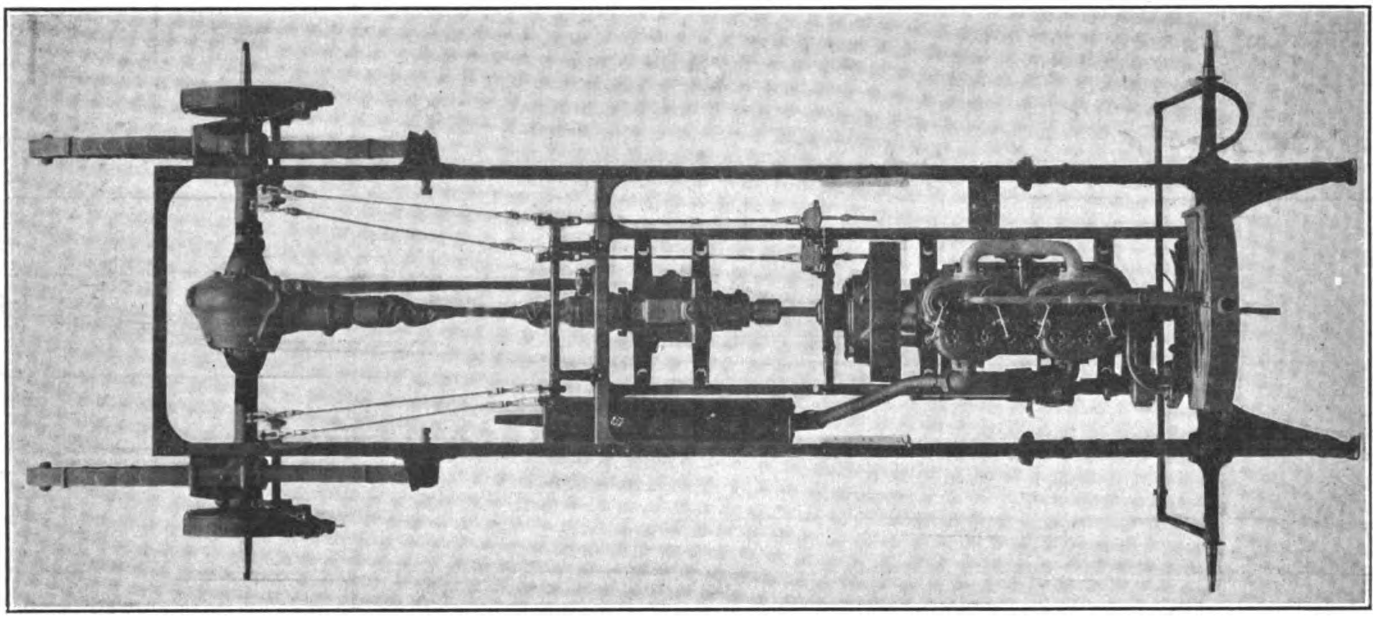

Fig. 1—Chassis of the Olds production known as Reo the Fifth; standard for all types of bodies

Reo the Fifth--Olds' Latest Model

WHAT is announced as the greatest achievement of R. E. Olds has been brought forward under the name of Reo the Fifth. It is fitted with a 30-horsepower motor and the chassis is provided with bodies of the five-passenger touring, baby tonneau and two-passenger roadster types.

The motor has four cylinders, which are cast in pairs. The water jackets are cast integrally with the cylinders and are of large dimensions to insure a positive circulation and avoid pockets in the cooling space. The motor is illustrated in Figs. 2 and 3, which show the left and right sides of the motor respectively. The bore of the motor is 4 inches and the stroke 4 1-2 inches, giving a stroke-bore ratio of 1.12. The intake manifold is of the Y-type and connected to the cylinders by means of stud bolts which pass through flanges on the intake manifold and into bosses cast integrally upon the exterior of the cylinder walls. The water intake pipe is led to the gas intake side of the motor through the small pipe shown in Fig. 2, and this is connected in a similar manner by means of flanges and stud bolts. The intake manifold is flanged at the Y and is so designed that as it leads from the carbureter to the Y it tapers gradually from a circular section to an elliptical section, the area being constant for the whole of this distance.

The inlet valves are located at the top of the cylinders and are operated by means of rocker arms driven off the camshaft. The rocker arms are located above the cylinders and may be readily seen in Fig. 3. The method of their operation is also shown in this illustration. The rods extend directly from the crankcase to the rocker arm and may be adjusted by the nuts located at the point where the rods enter the lower part of the crankcase casting. Stuffing boxes are located at this point in order that the oil does not leak from the base chamber to the exterior of the motor and give the same a dirty appearance after the motor has been running for a short length of time, not to mention the waste of oil which very often occurs from this point. The springs for the inlet valves are located on the upper part of the cylinders upon which they seat and are of sufficient strength to operate the rocker arms positively to preclude lost motion in the inlet valve mechanism.

The exhaust valves, located on the right side of the cylinders, are surrounded by the water jacketing to keep the parts, which are submitted to the excessive heat of combustion, as cool as possible. In order to make the cooling of the valve ports as certain as possible the water is led directly from the water intake to the exhaust valve and from there is allowed to circulate through the remainder of the jacketing. The exhaust manifold is connected to the cylinders in the same manner as the intake manifold. Larger bolts are of course used to sustain the greater weight. The manifold droops downward in a slow curve at the rear end so that there will not be any excessive back pressure produced at this point. The exhaust valve stems are upon the same side of the motor as the rods which operate the rocker arms for the intake valves. The adjustments for the valves are made in the same manner, the device consisting of a nut above

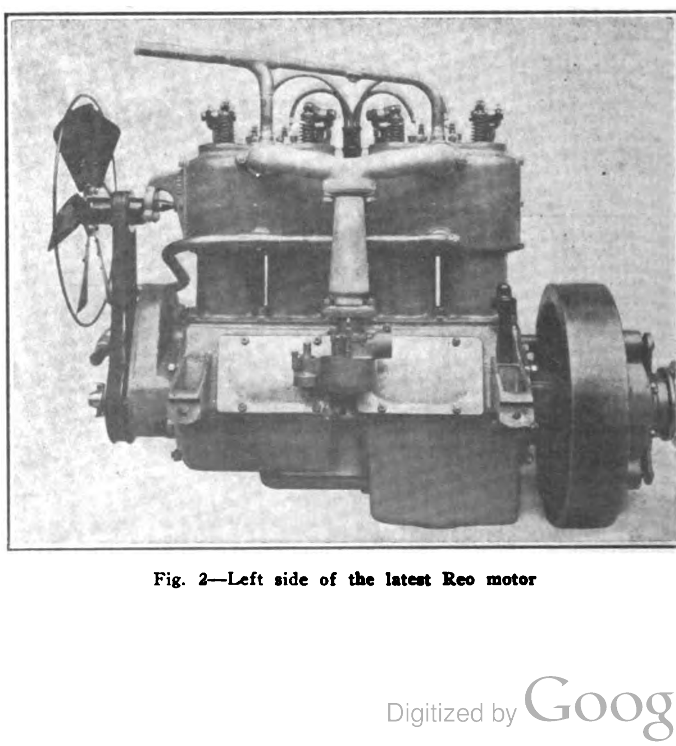

Fig. 2—Left side of the latest Reo motor

which there is a sort of cup in which the tappet rods rest. When there is any lost motion due to wear these nuts are turned in order to take up the space between the cup and the end of the tappet rods when the cams are at the lowest point. These points of adjustment are very accessible and are all upon the same side of the motor and at the same height so that they may all be inspected at the same time and the adjustment so regulated that they will be the same for each of the valve stems. In order to facilitate the inspection of the valve operating mechanism there is a cover plate over the lower part of the crankcase, which, when removed, discloses the entire cam action. This cover plate is held in position by means of stud bolts and dogs which pass over the cover plate. The stud bolts, of which there is one to each dog, pass through the center of the dogs and through the metal of the crankcase into bosses in the metal.

When it is desired to inspect the cams for wear or in case of trouble with these parts the bolts are removed; the dogs are then lifted out of place and the cam action is disclosed. The camshaft itself may be inspected or cleaned through this opening. The camshaft bearings may be removed through the opening, without disturbing the cams, by simply unscrewing the cover plates of the bearings. Inspection for wear in these places may be readily made in this manner without the expenditure of a great amount of time or labor.

The pistons are of gray iron castings, as are the cylinders, and are fitted with three sprung rings above the wristpin. The latter member is of steel and is provided with a bushing to take the bearing at the upper end of the vanadium steel connecting-rod. This is made as long as is consistent with a low engine, in order to reduce the thrust on the side walls and at the same time to keep the center of gravity of the car as low as possible. In order that the connecting-rods may be reached without removing the cylinder castings from the crankcase, there are hand-holes in the latter casting by means of which they may be examined and any adjustments readily made. Adjustments on the crankshaft bearings are made from the exterior of the motor, hence there are no assembling operations necessary after these adjustments have been made.

The cooling-water is circulated by means of a centrifugal pump located at the front end of the magneto shaft, which is extended forward for a considerable distance beyond the extremity of the crankcase on the right side of the motor. It is attached to the radiator by means of a short rubber tubing and draws the water directly from it. The water is then led through a nickel-plated tube to the opposite side of the motor and thence to the water jacketing. The outlet manifold is placed upon the

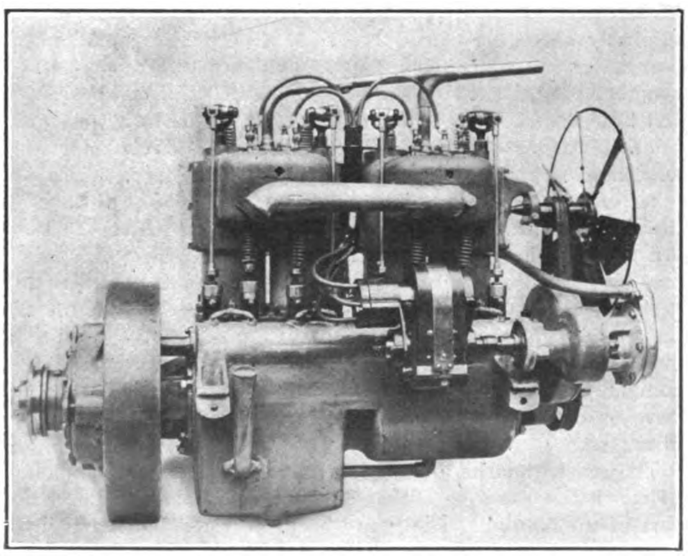

Fig. 3—Showing the right side of Reo motor

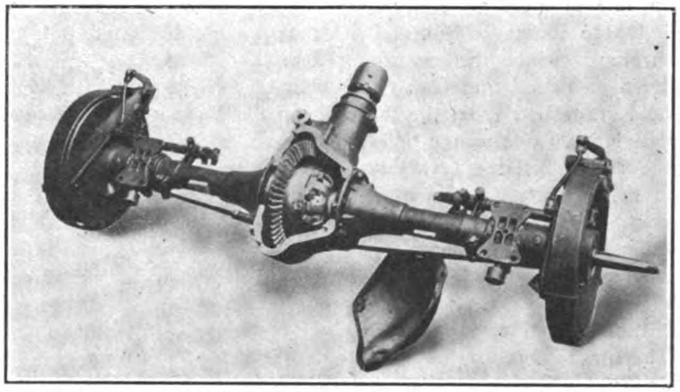

Fig. 4—A view of the rear axle with cover removed

top of the motor and slopes gradually upward to the top of the radiator, which is of the vertical tube type.

Lubrication is effected by means of a combination of the force-feed and splash systems. The oil reservoir is located in the lower part of the crankcase casting, which is of aluminum. The main supply of oil is carried in the tank formed by the depression of this casting, the capacity being in the neighborhood of 3 quarts. The filler hole is located on the right side of the motor near the rear end and is placed on the end of a tube which is an integral part of the filler. This filler tube is cast with a flange at the bottom by means of which it is held to the bottom of the crankcase by two bolts which pass into the base chamber. There is a screen in the filler hole through which all the oil must pass that is poured into the tank; this will insure a clean supply of oil to the tank at all times so far as any impurities which may be in the original supply are concerned.

The oil is taken from the tank by means of a plunger pump and led through the main lead to the main bearings, which are thereby lubricated. After passing through the main lead the oil flows into troughs, which are held upon a horizontal tray in the base chamber. These troughs are at such a height that the bottom of the connecting-rods will plunge into the oil for a distance of about 3-8 inch when they are full. The oil is caught up on the projections on the bottom of the connecting rods and beaten into a spray which pervades the entire crankcase, thus lubricating the pistons and all other moving parts within the motor. The camshaft bearings secure a liberal supply of oil by this means and there is at all times a mist of oil within the pistons themselves which will find its way about the oscillating bearing of the wristpin.

Since there is a superabundance of oil supplied by the pump there is no danger of the end troughs running dry either when ascending or descending a hill. However, there must be some means of permitting the excess oil to overflow so that the motor will not smoke. This is provided for by a series of overflow standpipes in the crankcase. The oil will pour through these whenever it reaches a point above the top of the splash troughs, and in this manner again reach the reservoir. In order that the supply be cleaned before it is again circulated through the lubricating system a screen is introduced through which the oil must pass on its way to the pump.

At the bottom of the reservoir there is a drain plug which may be removed for the purpose of draining out all the oil before renewing the supply. A separate oil lead takes the oil from the pump to the timing gear case at the front end of the motor, the revolving gears serving to distribute this oil about the case so that the gears work in oil and are at all times amply lubricated. After leaving the timing gear case the oil flows by gravity to the splash troughs in the same manner as it does after leaving the main bearings. The gearset and the differential are lubricated in the same manner as is usually employed in these parts. They are packed in non-fluid oil and are covered by grease-tight housings.

The carbureter fitted to the new car is so designed as to be capable of handling either high or low grades of gasoline. It is of the automatic type and fitted with a hot air intake pipe by means of which the gas admitted to the cylinders is kept uniform under varying climatic and atmospheric conditions. It is held suspended from the intake manifold by means of a broad flange and two through bolts which pass through the flange and the gasket inserted between the faces to guard against leakage at this point. Adjustment points are rendered as accessible as possible on the carbureter so that it may be readily set without taking it from the motor.

A low-tension magneto is fitted with supplementary dry batteries for starting purposes. The magneto and coil are of National make and produce a high-tension spark at the plugs. The magneto is carried upon the right side of the motor; it is driven by a short shaft which also operates the water pump upon its other extremity. The timer and coil are connected directly to the magneto, the wires being led straight to the spark-plugs after passing through a tube located between the two pairs of cylinders and fastened thereto by means of a metal strip which passes from the nuts which hold the rocker arms of the two central cylinders, around the tube which carries the wires. The tube is bent out toward the right side of the motor at the bottom, thus leading the wires directly to the magneto without allowing them to rub across any edges which could cause the insulation to chafe and eventually lead to a short circuit. The magneto is held in place by means of a metal strap which passes over it and holds the instrument tightly upon the shelf which carries it. Should it be desired to remove the magneto this can be effected by unscrewing the nut which holds the shaft in place, disconnecting the shaft and then withdrawing the magneto. The batteries or magneto may be used at the discretion of the operator by the manipulation of the switch which is located on the dashboard.

A change has been made in the location of the flywheel; it is set back 2 inches farther on the new model than on the models of the past year so that longer bearings may be used and the tendency toward vibration decreased. The clutch is located in the flywheel and is of the multiple disk Reo type, having alternate disks of bronze and steel. The housing is an integral part of the flywheel and may be seen in either of the illustrations of the motor. The clutch spring is inclosed and held in place by the casing cover, which is fastened by three stud bolts passing into the clutch housing. When these bolts are removed the whole clutch may be readily disassembled for inspection. The clutch is controlled by pedal in the usual manner except that it is manipulated by the left foot. The flywheel is so marked that it is possible to take down the motor and set it up by

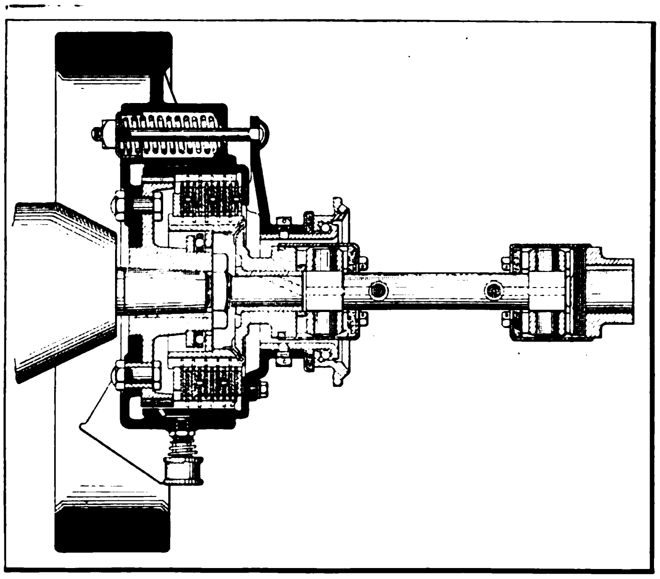

Fig. 5—Detail of the clutch used on Reo the Fifth

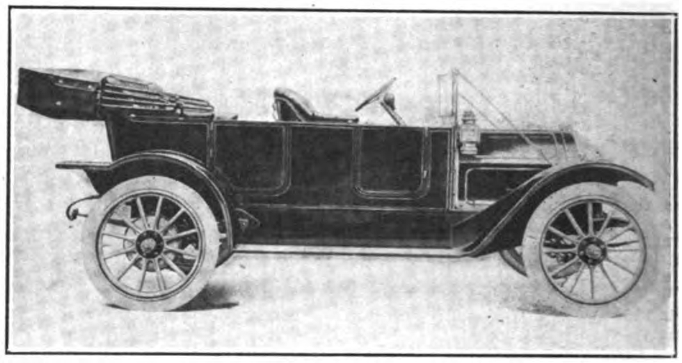

Fig. 6—Showing the five-passenger touring car for 1912

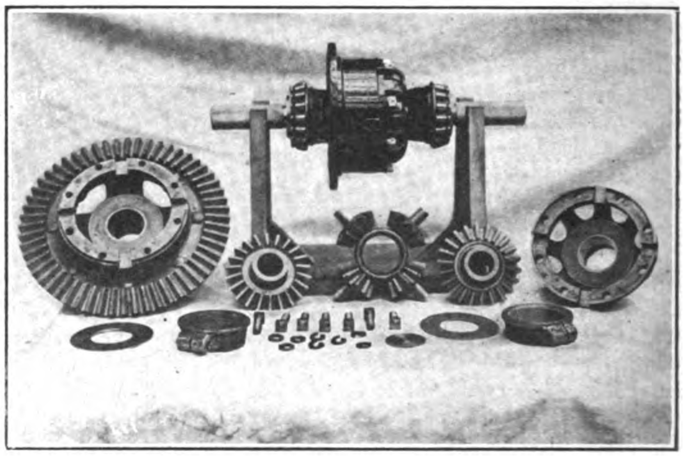

Fig. 7—A disassembled view of the differential gearing

means of these markings and still have the same timing. The marks consist of chisel cuts and the initials of the operation which is taking place at the time that the chisel mark is opposite the indicator on the engine frame. In this manner the opening and closing of both inlet and exhaust valves on all the cylinders are shown as well as the time in which any of the pistons reach either the top or bottom dead center.

The gearset is of the three-speed and reverse selective type. It is of compact design, as may be seen in Fig. 10, where it is shown in section. The gear-shift lever is of peculiar design, being fitted with a ball handle instead of the usual grip type of handle. The lever is located in the center of the car in a transverse direction, being on the right side of the driver, who occupies the left seat in this car. The gearset is very similar to that used on the Reo 1911 cars except that it has Timken bearings on the upper shaft and Hyatt high-duty bearings on the countershaft. The drive shaft is of nickel steel, bar hardened and heat treated; it is separated from the clutch by a universal joint, the casing of which is packed in grease. This joint will take care of any changes in alignment due to road shocks or other causes, and is kept continually supplied with lubricant by the grease which is fed to it through the gearset casing. Drains are fitted in the gearset housing by means of which the gears may be cleaned out and the supply of grease renewed whenever it should become necessary. The maximum travel of the top of the gearshift lever is 3 inches, so that in whatever position it may be located it should never be in the way of the driver. On account of the central location of the lever it is possible to leave or enter the car upon either side in the front as well as in the rear.

The gearset housing may be taken down by removing the bolts, of which there are eight, that hold the cover plate to the main part of the housing. The gear wheels, bearings and shafts may then be readily inspected and removed if it be necessary.

The drive is taken up beyond the gearset by means of a nickel

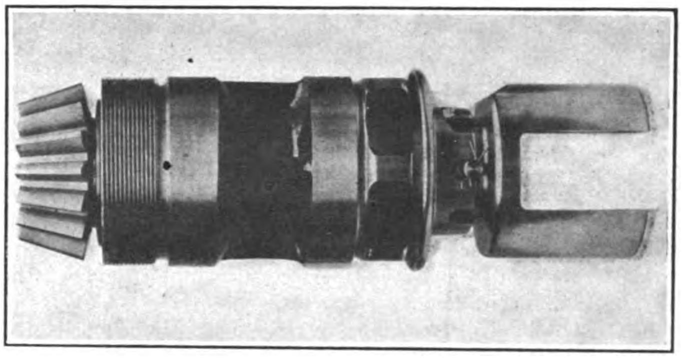

Fig. 8—The drive pinion of the differential is an integral member

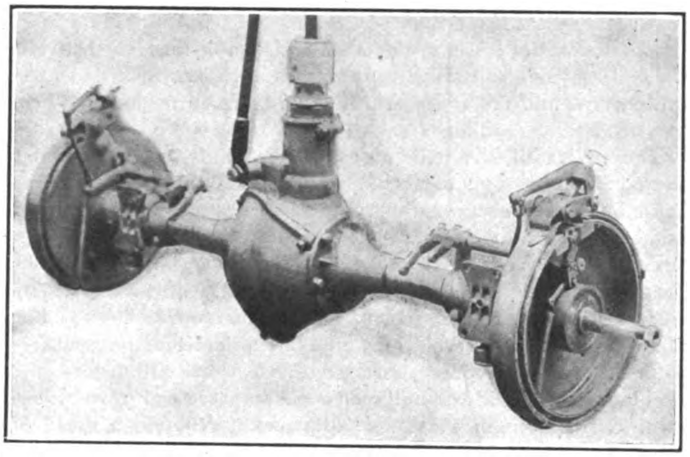

Fig. 9—Illustrating connection of torque rod to rear axle housing

steel propeller shaft separated from the gearset by means of a universal joint of the pin and block type to take care of the changes in alignment due to the varying passenger loads. This universal joint is also inclosed in a casing and runs in a bath of oil. At the rear end of the propeller shaft another universal joint of the same type is fitted and equipped with an oil-tight casing in the same manner as that just mentioned. The power is transmitted through this to the differential housing, which forms an integral part of the pressed steel casing in which the rear axle is contained. Leather boots are fitted over the universal joint casings, thus effectually sealing the part against the intrusion of any dust or grit, and at the same time keeping the part clean in case it is desired to do any work upon the universal joints.

The drive pinion through which the power is transmitted to and differentials is shown in Fig. 8; it is an integral part of the short shaft between the universal joint on the rear of the propeller shaft and the system of gearing in the differential casing. These gears are shown disassembled in Fig. 7; they are of heavier construction than those used heretofore in Reo cars and are made with the idea of noiselessness. To further this end they are carried upon roller bearings of Timken make throughout, while the fact that the drive pinion is connected integrally to its shaft does away with any possibility of lost motion due to wear at this point.

The rear axle is of the semi-floating type, being carried throughout on roller bearings of the Timken type, except that at the wheels the bearings are of the Hyatt high-duty type. Flanges upon the differential casing, to which are bolted the corresponding flanges of the axle shaft casing, form the means of connection between these two members of the rear axle housing. They are both of pressed steel. The accessibility of the differential may be judged from the view shown in Fig. 4, where the cover plate is illustrated as removed from the differential. The gearing, shafts and bearings are exposed sufficiently for the performance of any necessary adjustments. Torque rods are fitted to the rear axle housing for the purpose of stiffening the structure of the chassis and to avoid all torsional strains when making sharp turns or otherwise placing excessive strains upon this part of the mechanism.

The brakes are shown in Figs. 4 and 9; they are of the external and internal types, working upon 14-inch drums on the rear axle. The service brakes are of the external contracting type and are faced with thermoid. These brakes are operated by means of a pedal from the driver's seat. The emergency brakes are of the internal expanding type, working upon the same drums as the service brakes and faced with the same material. They are also controlled by pedal. Springs are fitted which keep the brake bands from dragging on the drums while they are not in use. Both sets of brakes are equipped with equalizers which distribute the pull on both brakes so that they are applied simultaneously and with equal pressure on the drums.

The frame is of Reo manufacture, the side members being of channel section and of single drop construction. The depth of the channels is 3 9-16 inches with 1 1-2-inch flanges. The front axle is of I-beam drop forged construction, having a single drop; the cross rod is to the rear of the axle. The chassis frame is supported upon 3-4 elliptic rear springs 2 inches in width having seven plates, and semi-elliptic springs in front having the same number of plates and being of the same width. The span of the springs is 38 inches. The steering gear fitted with the chassis is of the gear and sector type.

The wheels are 34 inches in diameter all around, and wheelbase is 112 inches. The equipment consists of three oil lamps, two gas lamps, generator, horn and complete tool and tire outfit for both the four and five-passenger touring models and the roadster.

British Favor Low-Power Cars

Day by day it is becoming more impossible in England to sell motor-cars of high horse-power. This is not entirely due to the fact that the popular demand of the times is for cars of moderate horse-power. Those who can afford to go to the expense are still keen upon such vehicles. But there is a vast difference between the 40- and 60-horse-powered automobile of to-day and the corresponding type a few years ago. While the modern car gives all the horse-power it is rated for, the oldtime car, with its enormous bore and short stroke, rarely ever gave within more than 75 per cent. of its nominal power. It has been suggested that in order to do away with the present tax on horse-power and still raise a corresponding amount of revenue, the taxation on gasoline should be materially increased.

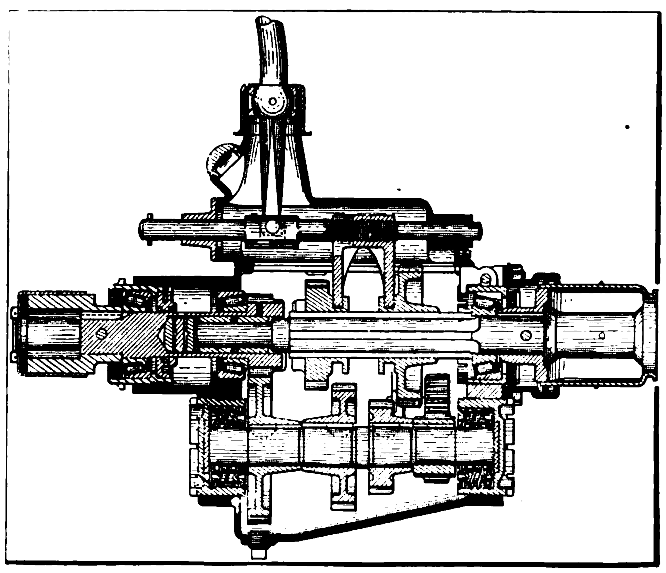

Fig. 10—Section through the gearset of Reo the Fifth

Destructive Driving-Shaft Oscillation

UNDER certain conditions of design, rapid wear of bevel gear on the rear axle of shaft-driven cars is observed and also of the universal joints on the shaft. And with some frequency it is noted that the ball bearings in which a cardan shaft is mounted at or near its ends, as well as ball-bearings on floating rear driving axles, are injured, without the injury being easily explained by the stresses to which they are considered subject. Some light is thrown on the causes which may be at work, and consequently also on the best means for avoiding the troubles referred to, in an article appearing in a German contemporary and rendered in substance in the following.

It had been observed that many cars equipped with bevel gear and shaft drive became noisy in the rear axle mechanism as soon as the motor speed reached a certain number of revolutions, and Engineer T. Lehmbeck undertook to investigate the cause of this phenomenon at the testing laboratory of the German Arms and Ammunition Works at Wittenau, Berlin, in conjunction with Engineer Bockermann, the superintendent of this laboratory. No attempt was made in the experiments to determine the rhythmic effects which may be caused in the operation of a car through coincidence or certain arithmetical relations in the vibrations of various parts with those of the driving shaft, as this would lead to great complications and to results which would not be generally applicable. The object was to decide by graphic methods the general principles ruling the harmful vibrations of driving shafts according to the length of the shafts, their design and the location of the fixed bearings in which the two ends—adjacently to the universal joints—are mounted. The trials were made with plain shafts of different lengths mounted in two ball bearings adjustably secured on the bed plate of a heavy lathe. One end of the shaft was coupled by means of an Eisemann joint with the shaft of a separately mounted electric grinder ordinarily used for micrometric material tests in the laboratory. An intervening expansion pulley drive admitted the variation of the number of revolutions from 500 to 3,500 per minute.

In order to measure the magnitude of the vibration of the shaft at the critical number of revolutions, a measuring apparatus was constructed consisting in a contact lever C with a lever arm ratio of 1 to 10. On account of the momentums this could not be laid upon the shaft, but the end of the index lever was taken in the hand of the operator and the contact point was cautiously approached to the shaft by turning it around its pivot until it was touched by the latter, and this manner of proceeding proved itself sufficiently exact to insure very accurate determination.

The shaft first used was turned and ground to a diameter of 30 millimeters (1.58 inch) and perfect straightness, and was in all 1,760 millimeters long.

Fig. 1 shows a diagrammatic plan view of the arrangements, together with a side view of the contact-lever apparatus, and it may be noted that the driving shaft A to the right of the coupling B is mounted upon the same bed plate to which the ball-bearings of the test shaft S are secured.

The first series of tests was made with the distance L1 between the ball bearings variously adjusted to 1,600, 1,400, 1,300 and 1,000 millimeters, and the free shaft ends L2 were correspondingly 80, 180, 280 and 380 millimeters.

The radius of the oscillations of the shaft resulting under these conditions, and measured at its middle, are shown in the solid lines of the curvograph, Fig. 2. That there is a critical number of revolutions corresponding to each shaft length (between the bearings) is at once noticeable. Soon after this number is reached, the vibrations subside quickly in all cases. By 1,480 revolutions, the radius of the oscillation reaches 8 millimeters, and at 1,570 revolutions only one millimeter more, whereafter it drops. With a shaft length of 1,400 millimeters, the oscillation reached a 7-millimeter radius at 2,030 revolutions. With a shaft length of 1,200 millimeters it required a speed of 2,725 revolutions before the oscillation became 6.5 millimeters and, when the shaft length was reduced to 1,000 millimeters, 3,070 revolutions produced an oscillation of only 2.5 millimeters. The power of the motor was insufficient to reach the maximum oscillation for the shaft lengths 1,400, 1,200 and 1,000.

In the second series of experiments it was the object to ascertain what effect the free ends of the shaft have upon the oscillations of the latter, and for this purpose another shaft of 1,850 millimeters length was employed. The bearings were placed 1,750 millimeters apart as in the first series. Subsequently, the shaft was made 250 millimeters shorter for each successive test, and the distance between the bearings was reduced the same, so that the free ends remained at the same length of 50 millimeters in all the tests. The curves shown in broken lines in Fig. 2 indicate the results recorded. The oscillations were plainly much less pronounced than in the first series.

In practice the conclusions of the experiments may be summarized as follows:

First, when the cardan drive shaft is mounted (in ball bearings) as close as possible to its ends, the calculation of the critical number of revolutions may be made according to Stodola's formula for a freely suspended shaft, but it is possible that even such short shaft ends as those of 50 millimeters, used in the second series of tests, exert an appreciable influence.

Stodola's formula calculated for steam turbines gives the critical number of revolutions as numerically equal to $\frac{r \times 10^4}{L^2 \times 1633}$, in which r is one-half the diameter of the shaft and L one-half the length of the shaft, both in centimeters. In applying this formula, L is to be considered as one-half the length between the ball bearings; that is, one-half of L1 in Fig. 1.

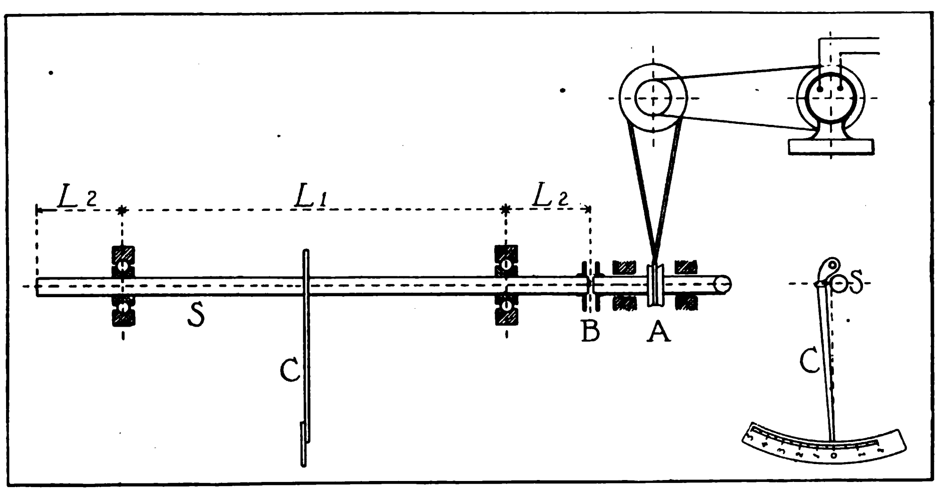

Fig. 1—Grand plan of arrangements for testing end-driven shafts for oscillation—with separate side view of contact index device

Secondly, the longer the shaft ends are which project from the ball bearings to the power at one end, and to the work at the other, the greater will be the oscillations of the shaft and the greater the loss of efficiency.

At the lower end, all cardan shafts are quite closely coupled with the small bevel gear pinion, but at the upper end there is frequently a considerable length projecting, and this explains why so many cardan shafts oscillate violently. In some cases the oscillations become so pronounced that the shaft strikes the enclosing tube and in the course of time spins it into the shape of a taper, as may be observed in a certain French construction. In some Adler cars with long cardan shafts the tube is flanged and joined at the middle to make room for a special ball-bearing to support the shaft at this point. Other constructors use lignum vitæ bearings, but with less satisfactory results.

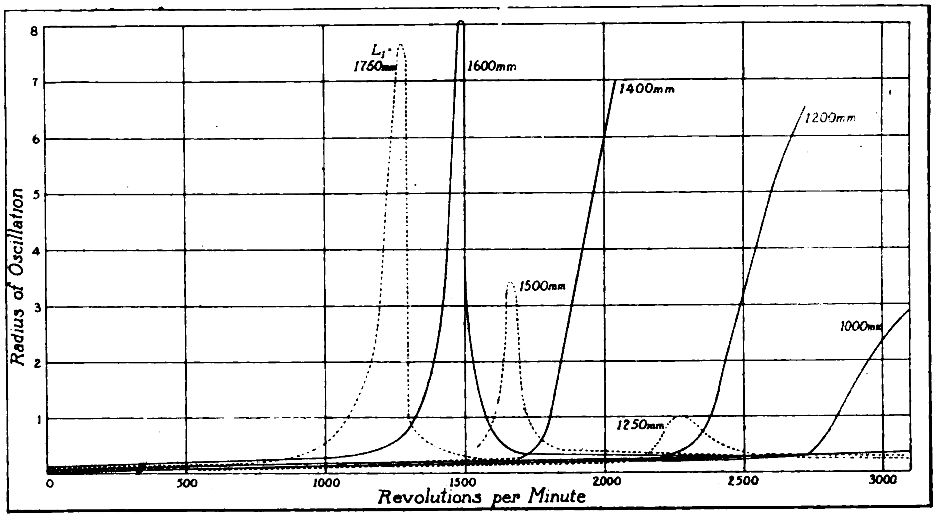

Fig. 2—Diagram of shaft oscillations in two series of tests. Figure at peak of curves indicates length of shaft between bearings

With regard to the design and workmanship of the shafts, it is of the first importance that they are perfectly straight, so as not to have oscillations from the start. Shafts which have not been turned will rarely run straight, and the slightest incipient oscillation causes an extremely rapid increase of the oscillation radius and soon results in the complete destruction of the ball-bearings at the ends. A good cardan shaft should be accurately turned with the diameter increasing toward the middle, and it is false economy to choose the dimensions too small, as a thin shaft of course vibrates much more than a heavier one and in course of time surely destroys every part coming in contact with it.

Further, a tubular shaft can probably never be made so uniform in the thickness of its walls as is required to avoid that centrifugal forces make themselves felt. The centrifugality starts the oscillations and then, when the critical number of revolutions is also reached, the destruction of even the most substantial ball-bearing is only the work of a moment.

With regard to the location of bearings, the practice of providing these, in the case of a simple cardan shaft, only at the lower end, while leaving the upper end at the universal joint unsupported, is to be condemned. To be sure it works as has been demonstrated often enough, but in that case the universal joint itself must be securely mounted in bearings and must be of very generous dimensions in order to resist the extremely high stresses which are set to work through the oscillations.

Oscillations of the cardan shafts may be recognized by the humming of the shaft at the critical number of revolutions and also by the noise suddenly emanating from the bevel gear on the rear axle; the cause being simply that the oscillations alternately increase and diminish the stresses in the mesh of the gear teeth.—From *Zeitschrift des Mitteleuropaeischen Motorwagen Vereins*. No. 21.

Three Cents a Mile for Car Operation

How much does it cost to run a 15-horsepower motor car 15,000 miles in one year? Here are some figures, based on actual facts, from experience and submitted by Mr. D. C. Defries, chairman of the Motorists' Mutual Co-Operative Society of England.

Tire replacement	$173.56
Petrol, 750 gallons at 27 cents the gallon	202.50
Lubricating oil, 50 gallons at 41 cents the gallon	20.50
Full insurance against all risks	45.00
Sundries (about)	25.00
Total	$466.56

The above figures do not include chauffeur's wages and garage hire. But Mr. Defries assumes that a man who does not employ a chauffeur, the work of cleaning the car being done by his gardener, should be able to run his car 15,000 miles on an outlay of less than $500 for the year. This amount of mileage per annum in England is nothing out of the ordinary and especially among physicians, who make strenuous use of the automobile in their professional circuits. One of the American automobile engineers who visited England during the Olympia Motor Car Show is quoted in the press as having designated 5,000 miles as the average year's run of an automobile in the United States.

British Motor Imports Increasing

The following tables show the amount of British imports, exports and Foreign and Colonial re-exportations of motor cars, chassis and parts during the month of October, 1910 and 1911:

	October, 1910		October, 1911	
	Number.	Value.	Number.	Value.
IMPORTS.				
Cars	329	$547,525	525	$655,535
Chassis	529	660,695	493	627,540
Parts	...	837,845	...	956,210
	858	$2,046,065	1,018	$2,239,285
EXPORTS.				
Cars	454	$879,210	630	$1,309,195
Chassis	47	95,165	79	147,405
Parts	...	551,855	...	600,780
	501	$1,526,230	709	$2,057,380
FOREIGN AND COLONIAL RE-EXPORTATIONS.				
Cars	93	$150,535	155	$279,385
Chassis	16	26,410	97	154,490
Parts	...	132,820	...	98,150
	109	$309,765	252	$532,025

Compulsory Colors for Public Cabs

Hereafter all public gasoline motor cabs operated in the city of Berlin, Germany, must be "marstallbraun" (a shade of brown) and all public electric cabs must be in "ivory colors." The president of the police board has so decreed, and, it is stated, that the principal reason for this restriction is to be sought in the excessive decoration, in loud colors and extravagant designs with flowing wreaths, luscious bunches of grapes and even bacchanalian symbols, by which the cab companies of the gay German metropolis have heretofore found it expedient to meet the supposedly vulgar taste of the populace. Even those who object to the prescribed monotony on principle are inclined to look upon it as the lesser of two evils.

To Keep the Oil From Carbonizing—The Metallurgique company of Montbard-Aulnoye, Paris, has the German patent on a piston in which there is a groove near the top, somewhat larger than the piston ring grooves to be filled with non-conductive material.—From *Der Motorwagen*, November 10.

Automobile Metallurgy Made Easy

By E. F. Lake

Part V

Impact—Vibration—Hardness Shearing—Bending

(Next Week—Bessemer Steel)

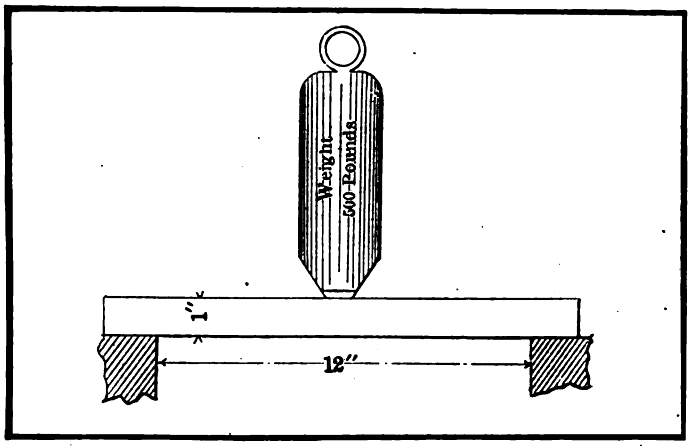

Fig. 1—Impact test

AUTOMOBILE materials have been given a number of strength tests, other than those mentioned in the four preceding articles. Nearly all of these tests parallel different kinds of strains and stresses that various parts are submitted to and they are all useful in their way.

All parts of the automobile vibrate continually while the car is in motion. Tests that will show how materials will withstand this vibration are thus beneficial. These tests consist of two kinds, namely, alternating and rotary vibrational tests. The front axle, frame, springs and the other parts that do not revolve are constantly subjected to alternating vibrations in a moving car, while revolving parts, such as the various shafts, are submitted to rotary vibrational strains.

Alternating vibrational tests are usually made by gripping a test bar, 6 inches long, by one end and then moving the other end 1-4 of an inch in opposite directions from its center line. This keeps the bar continually bending back and forth and the number of bends it will stand before breaking is given as the result of this test.

The rotary vibrational test is given by revolving the test bar at the same time that it is moving back and forth out of its center line. The bar tends in both directions with each revolution and the number of revolutions it will stand before breaking is given as the result. Crankshafts, gearset shafts, driving shafts and rear axle shafts all revolve to drive the car while it is traveling over the road, and they are being vibrated at the same time, by the car coming in contact with the road's uneven surface. Hence the rotary vibrational test shows how long different materials will stand this kind of work.

Impact tests are also given steel. These consist of resting the test bar on two supports that are a given distance apart and then dropping a weight on the bar, centrally between these two supports. This should weigh a given number of pounds and be dropped from a given height. Fig. 1 shows how this test is made. A straight edge laid on the test bar will show the deflection in inches that each blow causes, and thus its resistance to impact. The number of blows before the bar breaks is also recorded. If instead of dropping the weight a pressure were applied to it gradually the transverse strength would be obtained. This test is often used for cast iron and the number of pounds of pressure that is required to break each square inch of the specimen's area is recorded. Pendulum impact tests are made by swinging a weight against the test piece in the same manner that a pendulum swings. The foot-pounds required to break the specimen are given as the result. Impact tests are used very little for automobile parts, but they are well adapted for metals used for some other work. Railroad rails, that continually have heavy weights, in the shape of loaded cars, rolled on them between the supporting ties, are good examples of the need of this test.

Shearing tests are carried on for the purpose of showing how much a metal will stand before it shears off or cuts in two. This test is very applicable to the testing of rivets. The different

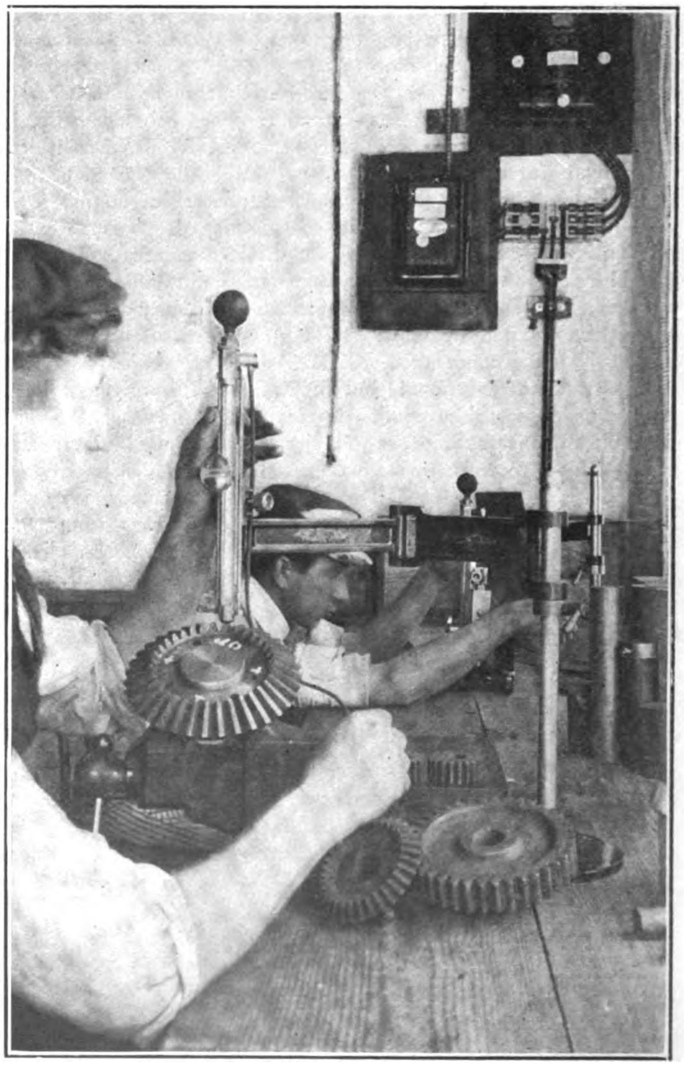

Fig. 2—Testing automobile gear teeth for hardness

pieces that go in an automobile frame have a tendency to slide past each other, from the twists and strains given the car. In thus sliding past each other they have a tendency to shear off the rivets. The leaves of springs do slide back and forth on each other until the center is reached. The central bolt, that holds them together, is liable to be sheared off by this motion continuing past the center. Other parts also have bolts and rivets that are liable to be sheared off. The steels that would be best to withstand this shearing strain could be adapted for use, if samples were first submitted to the shear test. The number of pounds pressure that is required to shear off a given size test bar is given as the result of this test.

Hardness tests are given in several different ways, or rather with several different instruments, each one having an arbitrary scale from which to give the results of the test. The degree of hardness of various metals that enter into an automobile is of importance as this affects all of the mechanical properties, *i. e.,* the tensile strength, elastic limit, contraction, torsion, etc. One hardness-testing instrument drops a ball on the metal and measures the rebound for its result. Such an instrument is shown in Fig. 2, testing the teeth of steel gears in an automobile shop. Another hardness-tester presses a ball into the metal and measures the diameter and depth of the indentation. Such a machine is shown in Fig. 3 and this also records on the dial the number of pounds required to press the ball into the test piece. Another instrument drops a weight on a lead disk placed on the test pieces and measures the amount of its compression.

The degree of hardness of such parts, as gearset gears, is of the greatest importance. These gears must be hard enough to wear well and at the same time tough enough to withstand the strain caused by the clash when they are suddenly thrown into mesh. If too hard the gear teeth will break off and if too soft they will bend out of shape and be useless. All the teeth around the circumference of a gear must be of the same degree of hardness and a testing instrument is very useful for proving this. All moving shafts must likewise have the proper degree of hardness to withstand the frictional wear of the different parts they come in contact with and that move with them. In fact, all of the various metal parts must have a hardness that will best enable them to withstand strains and stresses.

Another test given metals is the bending test, that is, one end is held stationary while the other end is moved enough to bend it around a plug of a given diameter. The number of degrees through which the test piece bends before it is ruptured is given as the result of the bending test. While this may be applicable to some automobile parts, it is seldom used as some of the other tests, heretofore mentioned, are made to take its place.

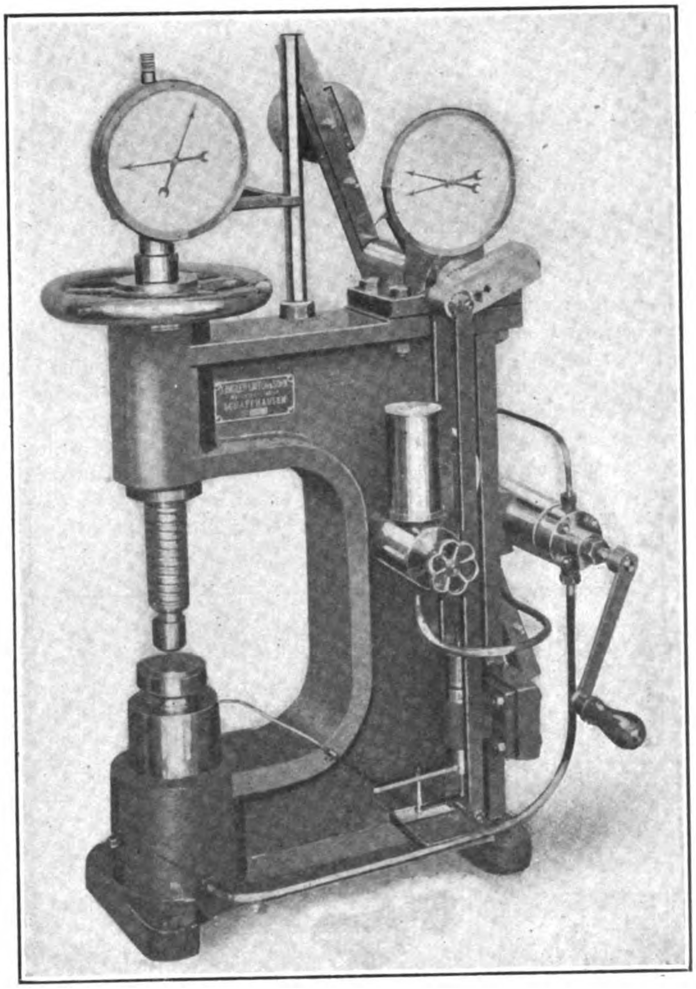

Fig. 3—Indentation hardness-tester

A test is also given to metals to show their frictional wear. The thousandth of an inch that wears off from a given area, in a given space of time, is tabulated as the result of this test. Such a test might be useful to show the life of bearing bushings or the parts that operate in them.

Harking Back a Decade

FROM *The Motor Review,* December 19, 1901:

The United States Circuit Court of Appeals sitting in Boston has affirmed the single-tube tire patent, known as the Tillinghast patent.

In its answer to the suit filed by Richard Siegman, at Trenton, the Electric Storage Battery Co. denies that it has diverted much of the capital stock of the Electric Vehicle Co. into its treasury without adequate compensation. It is explained that 48,000 shares of this stock were used to pay for the controlling interest in the Columbia Automobile Co., which was held by the battery company, but which is now owned by the Electric Vehicle Co.

The Diamond Rubber Co., of Akron, has increased its capital stock to $1,500,000. The company is now 6 years old, starting with a capitalization of $50,000.

The new Century car is of the tonneau type. Its wheelbase is 96 inches and there is no machinery above the floor except in the bonnet. The motor is of four cylinders and is geared to 35 miles an hour.

The retail automobile district of Chicago is steadily moving southward on Michigan avenue. Only recently the Winton, Milwaukee and Waverley have determined to move eight blocks south to Fourteenth street. Several other concerns will probably announce similar action in the near future.

F. B. Stearns & Co., of Cleveland, are busy building a racing-touring tonneau of 22-horsepower. A speed of 45 miles an hour is claimed for the new car. The company does not aim to become a large manufacturer, but is planning some additions to its present plant.

The Long Island Automobile Club held its first annual meeting and banquet last week. W. Wallace Grant was elected president and Frank G. Webb treasurer of the organization.

The British government has instituted a prize competition for a tractor for military purposes and an invitation has been extended to American automobile makers to take part. The first prize is $5,000. The tractor must be able to draw a gross load of 25 tons, 40 miles, at a rate in excess of 3 miles an hour and surmount grades not exceeding 6 per cent.

Digest of the Leading Foreign Papers

New Gear-Probing Methods

WITH the demand for noiselessness in automobiles and the desire to reduce wear and depreciation to a minimum, designers are turning their attention to suitable devices for testing the correctness of gear teeth curves, either in the shop where the gears are milled or through the facilities of the purchaser. A beginning in this direction, and one apparently susceptible of further development, is described by Moritz Kroll, of Pilsen, Germany, in the form of an apparatus which was first used for instruction purposes at the public trade school in that city. It will be noticed that the grosser inaccuracies due to eccentric mounting of a gear wheel on its shaft or to any curvature of the latter are shown up independently of those due to faults in the tooth curves.

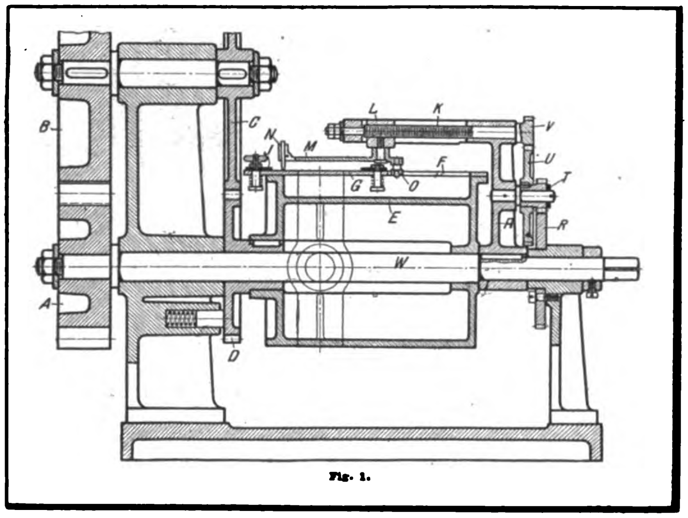

Fig. 1—Apparatus designed for testing and charting gear-wheel inaccuracies

Fig. 1 shows the first apparatus designed, which is applicable only to testing gear wheels of a certain size (15 teeth with 1 inch pitch), but whose recording device is sensitive enough for very minute examinations and enables the tester to locate and measure the inaccuracies. Fig. 3 represents a simplified model applicable to gears of different sizes and believed to be sensitive enough for industrial purposes, Fig. 4 represents the same general type adapted to the testing of bevel gears. Fig. 2 represents diagrams produced by the device under varying conditions.

Referring to Fig. 1, the spurwheel to be tested, A, is secured upon the end of shaft W and drives through the spurwheels B, C and D the parts E, D and E being free to rotate on shaft W. The gear ratio is 1. If the mesh between A and B is right, E therefore rotates with the same angular velocity as the arm P which is keyed to shaft W and formed with a horizontal branch K. Every error in the mesh of A results, on the other hand, in an advancement or retardation of the arm P with relation to the part E. A sliding piece L in the branch K carries a lever M whose short arm engages a slot in E while the long arm is provided with a pencil point N which marks a diagram on a strip of paper fastened to the part E. In the test, the shaft W is slowly turned one revolution by means of a crank. A pinion T, mounted upon the arm P together with another larger pinion U, is rotated by its engagement with the fixed pinion R and transmits the movement through the small pinion V to a threaded spindle in K whereby the sliding piece L, with the lever M and its pencil point, is shoved forward while at the same time the pencil point is also actuated by any relative movement between P and E.

The curve I in Fig. 2, which is nearly a straight line, was produced with a correctly milled spurwheel A in a certain relative position of the wheels A, B, C and D. Curve I' was produced by merely bringing other teeth on these wheels into engagement, and a defect in the workmanship of the apparatus was thereby discovered. The shafts upon which A, B and C are mounted had first been turned down, as is generally done, as far as to the collar and had then been reversed in the lathe to turn the reduced ends, but by this operation the latter had become very slightly eccentric, this accounting for the bend in the diagram. By placing the two shafts so that the eccentricity of one neutralized that of the other the diagram I' was obtained. Diagram II was produced from a wheel whose pitch circle was about one-half millimeter too small, while the depth of the teeth was correct for the right diameter.

Diagram III was obtained from a wheel which had been milled with a cutter intended for a wheel with 25 teeth, and diagram IV from a wheel in which three spaces had been specially milled

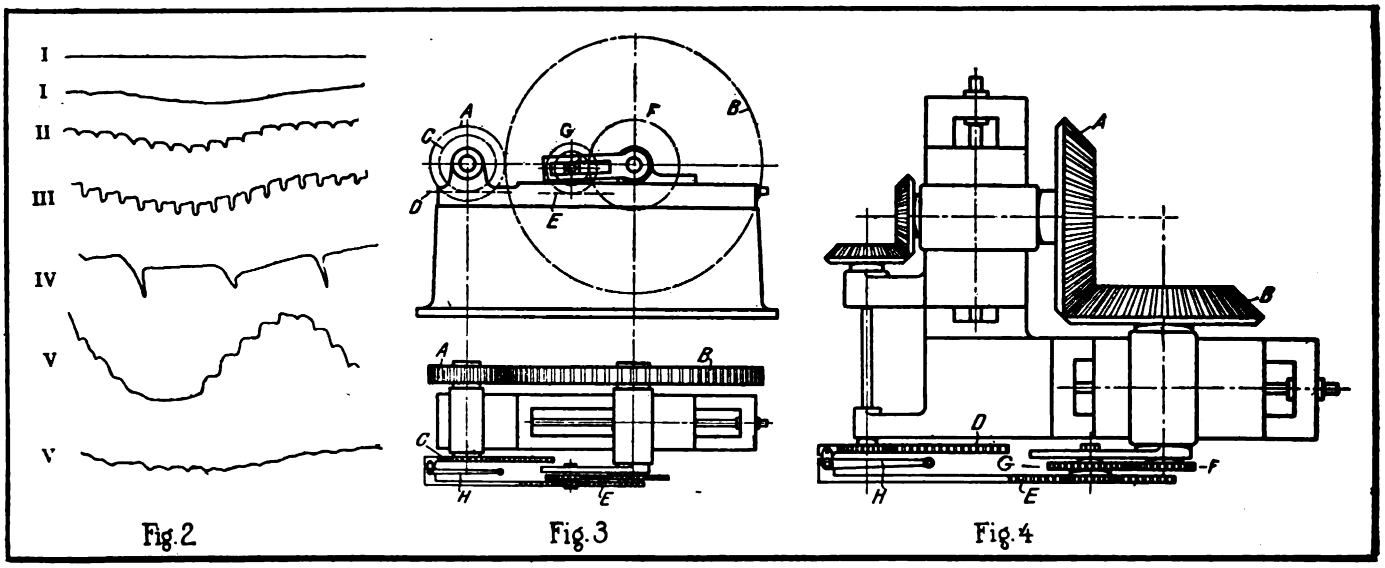

Fig. 2—Diagrams of various gear defects Fig. 3—Sketch of universal spur wheel testing machine, side and plan views. Fig. 4—Sketch of bevel gear and rotary machine, plan view

too deep, so that they were about one-half millimeter broader than the correct ones.

Diagrams V and V' show how strongly an eccentric mounting of a spurwheel on its shaft affects the mesh. The bore of a correct wheel was filed out on one side and wedged eccentrically upon its shaft. The double curvature of the diagram comes from the mesh being too close on one side of the wheel and too open on the other, while the small waves indicate the inaccuracies in the contact of the teeth produced by the misalignment. But when the wedge was inserted on the other side of the shaft diagram V was produced.

In an apparatus adapted for trying spurwheels of varying sizes, as shown diagrammatically in Fig. 3, one of the wheels to be tested, A, is mounted in bearings in the base of the apparatus; the other wheel, B, on a sliding carriage. A is turned a full revolution in the test, and the pinion C, which is mounted on the same shaft with A, thereby pushes a toothed rack D a certain distance, equal to the circumference of C. At the same time another rack E is pushed an equal distance in the same direction through a system of exchangeable pinions F and G, working from the shaft of B. Every fault in the mesh of A with B results in a relative advancement or retardation of the two racks. Rack E carries a bell lever H whose short arm is journaled in rack D, while the long arm carries a pencil point which writes the diagram on a fixed strip of paper.

To get correct readings from an apparatus of this kind it is the supposition that the exchangeable gear wheels, F and G, as well as the racks are properly milled, but if the pitch of these auxiliaries is made quite small, say, 1 to 2 millimeters, even the smallest of them will have a large number of teeth and their faults will show in the diagram curve as very low and short irregularities sharply distinguished from the higher and longer waves which will be produced by errors in the cutting of wheels A and P. The influence of backlash in all the wheels can be counteracted by suitable one-sided loading of the testing movement. The apparatus for testing bevel gears, as sketched in Fig. 4, differs only in having the two wheels A and B mounted on carriages of which one is slidable at right angles in relation to the other.—From *Werkstattstechnik*, November.

MUD SPLASHING—By a recent court decision in Germany two pedestrians were awarded damages from the driver (owner) of an automobile because the latter, though he had not been driving fast, was held not to have observed due caution to avoid splashing mud upon the two pedestrians on the sidewalk, and the case is exciting much comment in both automobile and anti-automobile circles. In France the same question has been taken up peaceably by the Automobile Club of Seine and Oise which has organized a contest, beginning February 5 next, for makers of anti-splash devices to be attached to or near the hubs of wheels on rainy and muddy days, and which must "not interfere with the esthetic appearance of the vehicles." The regulations for the contest provide that vehicles shall be driven through the mud at 25 to 40 kilometers per hour with the device attached, and as often as the jury of awards may decide to be necessary. The bespattering of the vehicle itself, especially its under surface between the wheels, will also be considered, as well as the time required for attaching the device.

MEASURING EFFICIENCY OF GEARS—Mr. Rikli describes in the *Zeitschrift des Vereines Deutscher Ingenieu·e* for August 26 an apparatus designed for testing gears under full load without great expenditure of motor power. The device recalls that used by Hopkinson for testing electric motors by grouping them pairwise in opposition. It is shown in Fig. 5. A motor M drives through a clutch K a shaft W1 on which are keyed two pinions r1 and r2. These are in mesh with two gear wheels R1 and R2, of which R1 is keyed to shaft W2, while the other is idle on this shaft and draws with it, by means of a dog, a sleeve with two flange plates T. On the end of shaft W2 there is keyed a plate S1 which drives plate S2 as in one with it, because an irreversible worm, journaled

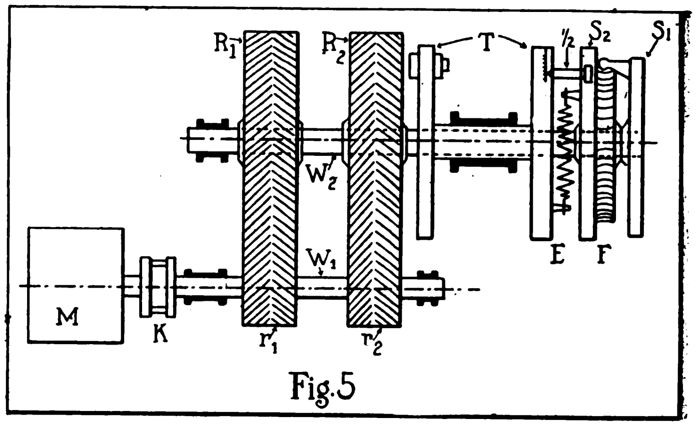

Fig. 5—Rikli machine for testing efficiency of gears

in S1, is in mesh with the helical gear wheel F secured to S2, and this plate S2 is attached to the adjacent plate of sleeve T by four springs E, which may be stretched to a desired tension by means of the worm.

The tension of the springs E determines the pressure sustained between the teeth of gear wheels R1, R2 and those of pinions r1, r2, and consequently the effort transmitted between these pinions, of which one may be considered the driver and the other the driven. By varying this pressure and the speed of rotation of the machine, it is therefore possible to modify at will the effective work of these pinions and to determine the efficiency of the gear, provided the power required for actuating the two gear wheels, which power is entirely utilized to overcome the friction in the gears and in the bearings, is known. The author tells of a series of tests made with this apparatus which admits of an accuracy which it has heretofore been found impossible to reach, owing to the high efficiency attained in gears and the multiplicity of the losses to be measured. —From *Le Génie Civil*, November 4.

FLAME-WELDING AND CUTTING—The oxy-acetylene flame gives a heat of 3,600 degrees Centigrade, the oxy-hydrogen flame 1,900 degrees and the coal gas or gasoline vapor flame fed with oxygen a heat of 1,600 degrees. Those who contemplate the purchase of an oxy-acetylene apparatus for autogenous welding or metal cutting should therefore not permit themselves to be influenced if it is represented to them that the same work may be done with an apparatus operating with hydrogen, gasoline vapor or illuminating gas as with one of the latest improved models of oxy-acetylene plants. A description of suitable acetylene generators and of the most recent British improvements in burners is offered in *Der Praktische Maschinen-Konstrukteur* for October 12.

PERMANENT DEVELOPER—Tourists who prefer to develop their own plates or films will be interested to know that a bath composed of 10 grammes of paraphenylene-diamine, 30 grammes of bisulfide of soda at 35 degrees, 3 grammes of bromate of potassium and 40 cubic centimeters of caustic soda (sodium hydroxide) at 30 degrees, if bottled and protected against atmospheric influence, will keep almost indefinitely. The author has developed plates with a bath which had been prepared for more than one years.—J. Desalme in *Bul. Soc. Francaise de Photographie*, reported in *Revue de Chimie Industrielle*, November.

ACCORDING to the *Daily Consular and Trade Reports*, the use of motor mail vans is still being extended in England, and over 100 services or sets of services are being performed by this means. Failures and serious delays are now of comparatively rare occurrence under normal conditions, and the greater speed of motor as compared with horse traction is of considerable advantage to the mail service.

Letters Answered and Discussed

Trouble with Patches

EDITOR THE AUTOMOBILE:

[2,958]—I am having considerable trouble in getting patches to stick to the inner tube. I am sure that the cement I am using is of the best quality, yet I do not seem to be able to get results. I would greatly appreciate it if you would give me a few tips on how to manipulate the gum. TYRO.

Clarkesville, Tenn.

The probable cause of your failure in applying the patches is that you do not have the rubber sufficiently clean. This is a point that is very frequently overlooked by amateurs. A piece of sandpaper should be used as in Fig. 1. When assiduously

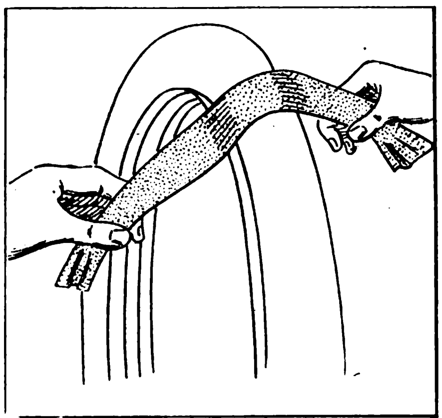

Fig. 1—Method of cleaning a tire with sandpaper

applied this will remove any excess dirt from the rubber and greatly assist the work of repairing. If the patch is not applied until the rubber cement is nearly dry it will often hold better.

Has Crankcase Explosions

Editor THE AUTOMOBILE:

[2,959]—Being a constant reader of your publication I take the liberty to ask for a little information concerning the oiling system of my car.

This motor has a filler on the right side of the crankcase and a large breather on the left. Now very frequently there is a light explosion in the crankcase, which one would judge at first to be crankcase compression, but on account of so much smoke and the odor of same I now think this an explosion of gas. About one-half the time this explosion will pass out through the breather, the other half through the filler, taking with it about one-half pint of oil. I put the blame on the oil at first, but have

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

tried the very best grades of oil on the market and it is the same old story. This motor has a constant level splash system and the overflows from the crankcase to the oil pan below are open, so, of course, the amount of oil in the pan, unless it was too full, would make no difference. The breather is open for one time it will relieve the pressure and again it won't. The condition of the road makes no difference, for this explosion occurs while going fast or slow, on level ground or up and down hill.

I will appreciate any information THE AUTOMOBILE can give me, and would like to hear from some of the readers who have had similar troubles. OWEN.

Minden, La.

The gas probably leaks past the piston rings on the compression stroke and accumulates in the crankcase where it is finally fired. This crankcase explosion will only occur in case the piston rings are so badly worn that the flame from the burning charge will flash past the bottom of the piston and ignite the inflammable gases which have accumulated within the crankcase after a series of compression strokes have allowed a sufficient amount of gas to leak down into the crankcase. There is also a probability that the breather pipe has not been kept as free as it should be on account of the screen having become choked with accumulated dirt. By removing this dirt and renewing the piston rings. There is also a possibility that there is a blow-hole in the top of the piston casting which allows the gas to penetrate the crankcase, or a very slight possibility that the cylinders are scored deeply. A good method of ascertaining if the cause of the trouble comes from any of these sources is to test the motors for compression.

Renewing Clutch Leather

Editor THE AUTOMOBILE:

[2,960]—I have a car on which the clutch leather facing is worn and which I desire to renew. Would you kindly tell me the kind of leather to use and the method of applying the same to the clutch member?

Mechanicsburg, Ohio. E. R. S.

When removing the rivets from the old leather care should be taken not to tear the leather so that it may be used as a template in cutting the new leather. This should be cut from the thickest part of the hide. The old facing is laid over the new and the position of the rivet holes located thereon by marking through the old holes with a pencil. The rivet holes are then cut and countersunk so that the rivets will be well below the surface of the leather. The rough side is turned out. The fitting has to be very carefully done and a superior job is made if it is trued up in a lathe. It should then be soaked in castor oil and will be found to apply itself to the female member of the clutch.

Wants Valve Information

Editor THE AUTOMOBILE:

[2,961]—I have several times read that there should be no lost motion in the valve action. All the advice I received through the reading of various books and publications led to my investigating the valve rods on my car and after a large amount of trouble I located some clearance space between the tappet and push rods. I was just about to adjust the rods so that there would not even be this small amount of space when I was told by a man whom I know to be somewhat of an authority on the subject that I should leave the clearance as it was since the rods expanded when the motor was running owing to the heat. Now

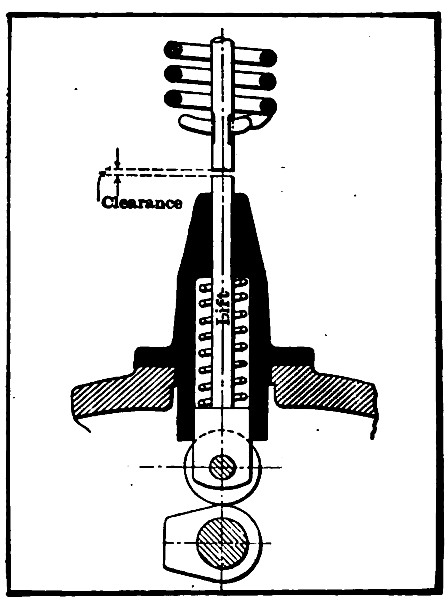

Fig. 2—Valve tappet having no provision for adjustment of clearance

I am all at sea on the subject and wish that you would clear up the mystery for me. M. Beppo.

Allentown, Pa.

The mystery is readily explained since both parties gave you the correct advice. Since the clearance which should be left at the point shown in Fig. 2 will close up after the engine has become warm, there will be no lost motion at this point. This will be the case whether there is an adjusting device on the stem or not. On all cars built within the last few years, however, this device will be found. The adjusting device is shown in Fig. 3 and should be tightened up so that there will be just sufficient clearance at the point designated, that a visiting card may be inserted between the two members of the rod.

Belittles New Motor

Editor The Automobile:

[2,962]—In The Automobile of November 12, appeared an article entitled Tesla's New Mechanical Principle. To anyone interested in the description of the new motor, which is to give such high thermal efficiency, I should like to suggest the reading of an article designated Bladeless Turbines printed in *Engineering*, London, dated November 10.

The article deals with Tesla's motor from an engineering standpoint and, in my opinion, shows the fallacy of the principle used. M. H. W.

Chicago, Ill.

The article referred to contains a criticism of new experiences on a basis of old-approved formulæ, proving the impossibility of constructing a motor as the one in question.

We remember a certain Robert Fulton, who steamed up the Hudson, even while his act of doing so was pronounced an impossibility by his fellow-citizens, as well as the example of one Knight, whose construction was scoffed at and considered impossible at the very moment it was propelling an automobile through the streets of Chicago.

These examples, with a score of others in history, show that formulæ are nothing eternal and unalterable, but that they hold good quite as long as they are applied to the conditions they were made for, and that, when new experiences come up, it is the formulæ that have to be adapted to facts and not *vice versa*.

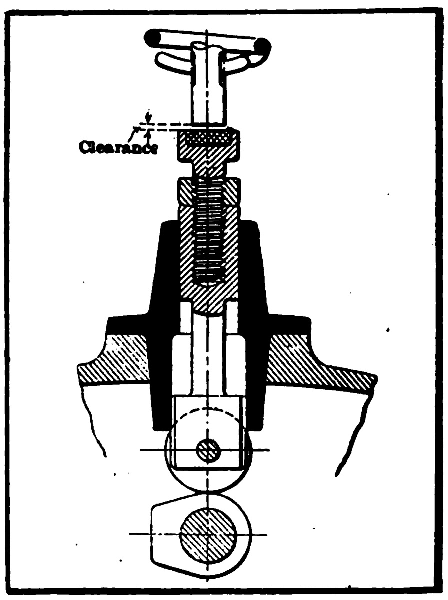

Fig. 3—Tappet of better design, showing adjusting device

Interested in Self-Starters

Editor The Automobile:

[2,963]—I notice some self-starters that are being shown in the journals which obtain a sufficient charge of gas from the acetylene tank by the suction of the engine on the opening of the gas line after cutting out the ignition, which it is claimed will start the motor after standing several hours by merely turning on the switch.

Will you kindly explain in the letter columns of The Automobile how this is accomplished and why the acetylene will do this when the gas from the carbureter will not. Do you think that starting the motor in this manner would strain it in any way?

Newcastle, Pa. J. H.

There are no self-starters using acetylene which rely on the suction of the motor to draw in a charge and then start on the spark in the manner you describe. The acetylene self-starters either allow the gas to flow into the cylinders under pressure or the gas is forced in by means of a small hand pump. Self-starters are not made with the idea of starting the motor after it has been at rest a few hours, but are intended for the purpose of starting at any time.

Front Tires Wear

Editor The Automobile:

[2,965]—One of the strange features about my tire troubles, of which I feel that I have had more than my share, is the fact that the front tires wear out much more rapidly than do those attached to the driving wheels of the car. I do not know how to account for it exactly as the tires on the front wheels seem to be worn on the outside more than on the inside. I would greatly appreciate it if you could tell me through the columns of The Automobile what the causes of this trouble could be.

Cornwall, N. Y. Edward Bronsveld.

It is very evident that the front wheels are out of alignment. This may be readily determined by the method shown in Fig. 4. A tape measure is used to find the distance between the two inner edges of the rims of the front wheels. The wheels are then turned to different positions and the distance measured at the same height above the ground in every case. A rather ingenious method, but one which is not so accurate, is to apply whitewash to the tires and spin them to see if the lines of whitewash thrown off are parallel.

Loss of Compression

Editor The Automobile:

[2,964]—I have a car in which the motor does not develop the power it should, due to one of the cylinders losing compression past the piston rings into the crankcase. I put on some new rings but it did not seem to do any good, when I put on the new rings I noticed parts of the rings were worn bright and other parts had dark places on them. Will you please tell me the best and proper way to overcome this leakage. F. A. Nelson.

Rupert, Idaho.

The correct method to use in such a case is to have the cylinders rebored. They are evidently worn irregularly if the piston rings are not bright on all sides and you are losing compression. This will have to be done by a reliable concern or

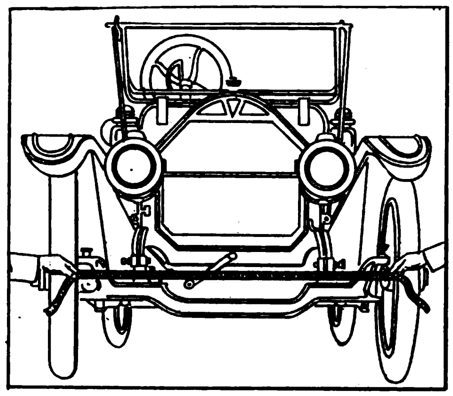

Fig. 4—Showing method of aligning front wheels

the motor will be hopelessly ruined should the work be carelessly done. The factory would be the best place if it is not too far away from you.

A Worthy Cause

Editor The Automobile:

[2,966]—Will you kindly allow a little space in the pages of The Automobile for the following few lines: I am a teacher of foreign languages in the Benjamin school, 144 Riverside Drive, New York City, and in my spare time I am endeavoring to do philanthropic work. The Cherry Tree Home for Children in Spring Valley, N. Y., needs very badly a vehicle that would serve to carry the children.

The manager of the school, Major Erberich, asked me to see what could be done for the purpose. They are willing to give a small sum for it, but we thought that at this season of the year there might be someone who would donate a new, or even an out-of-date automobile for such a worthy cause.

New York City. Anna Diehl.

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

SOLDERING FOR AMATEURS—Hundreds of burnt fingers and other proofs of an active interest in the art of soldering on the part of tyros go to prove that this apparently simple operation has its difficulties and puzzling features. Solder is the metallic parallel of the glue used in connection with woodwork and other work in which this fluid plays the part of a connecting agent. To define solder is impossible, as there are so many compounds which bear that name that a lengthy list would be required to mention all the compositions which are used for the purpose of making metallic joints.

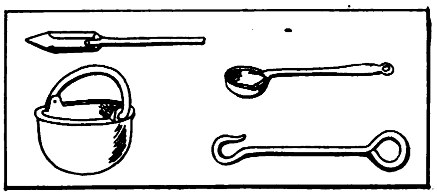

Fig. 1—Tools used in soldering

Common features in all solders is that they have, as a rule, lower melting points than the metals which they connect and they are weaker than most metals, so that a soldered joint is never made where it is required that the joint be particularly strong. If strength is required, the joints are either brazed or welded. These, of course, are more costly operations than soldering, but are of much greater strength. In many of the welding operations the joint is stronger after it is made than the metal itself.

The correct solder to use varies with each metal so that it is impossible to describe soldering in general, although the necessary steps which are common to all work of this nature may be mentioned by way, perhaps, of explaining the cause of a possible failure where the correct solder has been used for a certain piece of work, and yet where that work has proved other than a success. The first point to be observed is that the metal must be scrupulously clean. The metals are then heated to a point where they will unite with the solder in making the joint and covered with a flux so that the surfaces will be maintained absolutely clean. The solder is then applied with a soldering bit and the metal joined together. The joint is then cleaned and finished and allowed to thoroughly cool. The flux may be applied to the metal before it is heated if it is of borax or resin solution, but if it is a liquid it is better to heat the metal and then apply the flux.

The cleaning is accomplished by means of a rag which will remove all grease and leave the metal about to be joined perfectly dry and free from grease. A scraper and file are then called into requisition and the parts to be joined are made bright. The effect of the flux which is applied is to eat away the film of oxide which accumulates on the surface of the metal.

The solder, which is in general a lead and tin combination of various proportions, is then melted on the hot metal by means of a gasoline torch, Fig. 4 or in the case of smaller work this is often done by means of a candle. Where a soldering bit is used, this is heated to a low red heat and then pressed against the solder, causing it to run over the surface of the metal. The metals must not be too hot as they will then tend to oxidize in spite of the flux or will make the solder too fluid. Soft solder, which is used in the majority of small jobs, consists of 1 part lead to 2 parts tin. The flux used will vary with the metal to be joined. Zinc chloride is used with lead, zinc, copper, etc. Aluminum should be welded.

TEMPERING OF TOOLS—The subject of the hardening of metals of many different sorts has been of interest to humanity as far back as we have any record in history. The old art of tempering certain forms of metal has been lost to some extent although marked improvements have been made in this direction in the past few decades.

All those who do any extended work with tools should know how to temper them, as it will be found that the necessity for so doing will often occur. This is especially so in the case of a garage where the work done is in most cases upon hard metals and with tools which require frequent grinding. Skill in the art of tempering can only result from experience, as personal judgment is the most important factor in connection with the work. Tempering processes require a rather more complicated apparatus than that usually made use of in the ordinary operations of forging. Care has to be taken in the tempering process that unequal cooling or heating shall not occur; for if it should, the internal strains in the metal caused by the unequal expansion or contraction of different parts of the same piece of metal will cause a break in the metal.

There is no satisfactory explanation as to the reason that the metal assumes different shades of color as it reaches different degrees of hardness nor why a sudden change of temperature should harden the metal. It is only known to be a fact and although several theories have been advanced which seemed to fit a large number of the phenomena, there are other points which still remain unexplained. It is for this reason that absolute directions as to how to go about tempering a certain piece of metal cannot be given. Experimenting is the only possible way to obtain definite knowledge, although a few of the salient points may be pointed out which will act as a guide to those who are interested in this form of work.

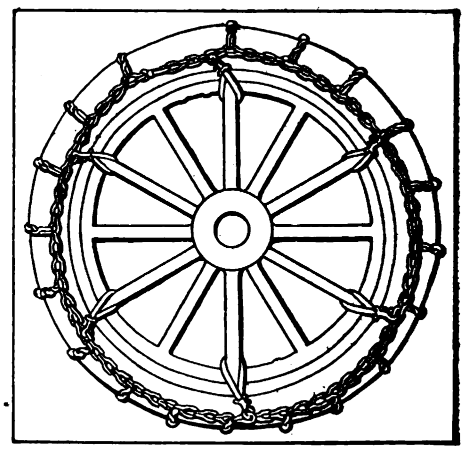

Fig. 2—Wrong way to apply chains

The first point to be observed in the cooling process is that the bath should be so arranged that there is no irregular cooling or, what is the same thing, irregular contraction, for such severe stresses are set up within the metal if this takes place that it will generally be very apt to become distorted or broken. Most tools are of wedge-like formation, so that care must be taken that when they are immersed the thick end of the wedge is always placed in the bath first. This is particularly true of tools which are in the nature of wide chisels. A wide chisel is very apt to crack if placed in the cooling bath with the cutting edge first, and another point to remember is that the temper given to a tool when the cutting edge is the first to go into the bath is irregular, the metal gradually diminishing in hardness from the point or edge.

It is almost useless for any novice in the art of tempering to pick up a book on the subject and read the explicit directions which are often given regarding the color which the metal is allowed to attain before it is plunged into the cooling bath. This is a thing which will have to be seen more than once before the tyro in the art will be able to accurately gauge the delicate shades which fade into one another so smoothly and withal so rapidly. When steel which has been raised to a red heat is plunged into cold water it becomes excessively hard and brittle; the more suddenly the heat is abstracted from the metal the harder and more brittle will it become; but in order that it shall have qualifications necessary to be of any use it must be tough. This toughness is given to the steel by a process of tempering. In order to produce steel which will have this quality to a necessary degree the metal is reheated and when the film of oxidation, which changes color with the variations in temperature, reaches the desired shade, the metal is cooled quickly and regularly by immersion in the bath most suited to the requirements of the temperature at which the part is to be chilled.

In ordinary mechanics' tools the tempering process is carried on by first heating the metal to a bright red heat whereupon it is plunged rapidly into the water and then withdrawn. A scale will form on the outside of the metal which is immediately scraped off. As the surface only has been cooled by the short immersion which has been given the tool the interior of the metal will still be at practically the same temperature that it was before the tool was plunged into the bath. Owing to the conductivity of the metal the outer crust of the metal will be gradually reheated by the interior and will acquire various tints which correspond to different temperatures. When the shade is reached that has been determined by experience to be the best for the work in hand, the metal is plunged into the bath and rapidly stirred about so that the cooling will be equal throughout the entire piece.

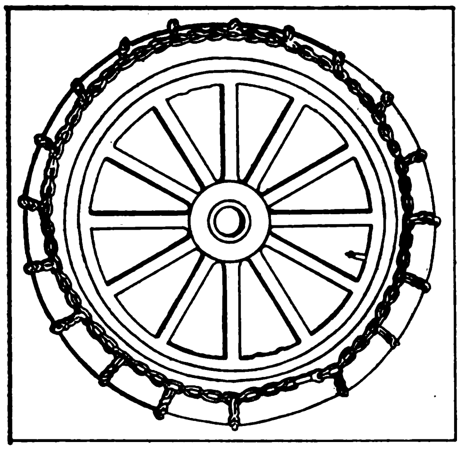

Fig. 3—Right way to apply chains

In small tools, which are so thin that the interior is cooled at the same time as the exterior when plunged into the water, a hot plate is brought into requisition for the purpose of reheating the metal to the required shade.

There are several ways of heating steel parts to bring them to the required temperature for quenching, as the first plunge into the bath is called. They may be heated over an open fire, heated upon a hot plate, on a pan over a charcoal fire or, in the case of small articles, by placing them in oil which has been raised to the correct temperature or in a molten alloy. The principal thing to remember, however, regardless of how the piece is heated, is that before quenching the temperature of the metal should not be excessive. In the better grades of steel a low cherry red will suffice. A gauge as to the hardness of the metal after it is dipped may be readily obtained by trying it with a file. On the other hand, if the steel is not properly hardened it cannot be satisfactorily tempered. Cold chisels and iron-cutting tools are chilled at a temperature of about 490 degrees Fahrenheit, which corresponds to a very dark straw yellow color.

Non-Skid Chains Tear Tires—It may be well said that non-skid tires are to a great degree more of a necessary evil than a delight to those who are compelled to use them. It should always be remembered that when these tire chains are fitted they should not be confined so that the links in the chain are continually over the same spot but they should be allowed to creep along the surface of the tire. If any one of the links in the chain is continually pressed against the same spot in the casing of the tire it will gradually imprint itself into the rubber.

It is very easy to see what the effect would be if the chain had sunk into the rubber for any distance and the car were to swerve suddenly. A tearing effect would be produced which would be very apt to result disastrously to the casing eventually. Chains should never be fastened to the spokes of the wheel, as is often done. This is the surest way to invite rapid wear.

Another point to remember in the application of chains is that they are not intended for use on city streets where the hard pavements will greatly augment the wear that the chains are inclined to cause. The chains find their best field of use in the soft mud of the country roads, where they are admittedly a necessity and where they are not backed up by a hard under surface which presses them into the tire casings. The greatest injury will result to tires when they are used on asphalt or similar roads.

Underinflation a Cause of Trouble—The evils of underinflation have been dwelt upon to such an extent in late years that there are few who have not heard a detailed account of the results of this form of neglect. Still, it might not be amiss to point out some of the more serious results of underinflation which have been the experience of those who have had the opportunity to see these results demonstrated in a practical way.

After a period of running while soft the tire will start to take on a baggy and out-of-shape appearance which will first demonstrate itself in the looseness of the tread. If the abuse is continued the looseness will become aggravated until it finally reaches such an advanced stage that the tire casing will be found, upon examination, to be distorted in a series of parallel ridges which run across the face of the tread. This wavy condition cannot be cured when it is once started, and a tire that has attained this shape is well on its way toward the scrap heap.

This particular case of tire trouble is one which strongly brings forth the old adage concerning the ounce of prevention, as a few extra strokes on the tire pump are all that is necessary to safely avoid any injury of this nature. The small cost of a tire gauge is well repaid by the good it can do in this direction, for by noting the pressure and following the directions of a reliable inflation table it will be found that this trouble is never experienced. Besides the ill effects on tires, the rims are damaged by underinflation, as whenever the car passes over even a slight ridge, the rims are apt to be cut by impact with stones or ruts.

When the car is turning a corner and the tires are not sufficiently inflated the bead will lift from the rim and pinch the tube between the bead and the rim. The result will be that the tube is cut and a blowout occurs. Before attempting to replace the outer bead in the rim-casing the tube should be slightly inflated and the hand passed inside the casing to make sure that the tube is not twisted or caught under the security-bolts as this would also cut the tube.

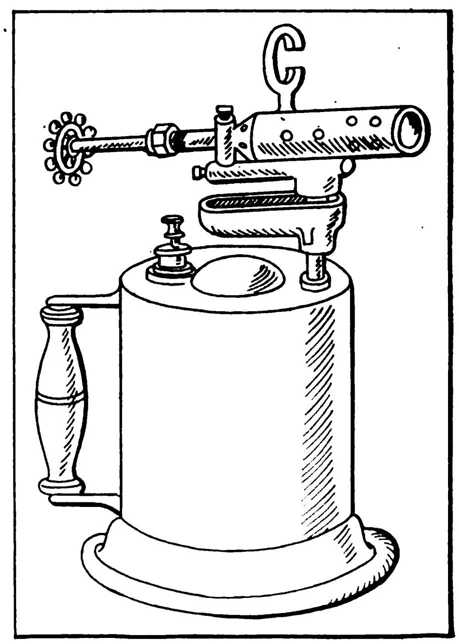

Fig. 4—Gasoline torch for soldering

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

Features Accessibility

EDITOR THE AUTOMOBILE:

My ideal car for 1912 should be built as follows: The motor should be a T-head type with long stroke. There should be six cylinders cast in pairs with dimensions of 4 1-4 inches by 5 1-2 inches, and the maximum speed should be 1,800 revolutions per minute. The 2 1-2-inch valves should be covered with easily-removable protectors. The crankshaft should have five ball-bearings and it should be offset 1-2 inch. The pistons should be removable from below.

The motor, clutch and transmission should be built as a unit and suspended on three points by the top half of the crankcase which should be made of bronze. A Bosch magneto should be on the left or exhaust side of the motor, and a hard rubber bar should be used to simplify the wiring for both magneto and battery plugs which should be over the intake valves. A large centrifugal pump should be placed on the right side of the motor with large connections leading to the cylinders and the honeycomb radiator. The radiator cooling should be augmented by a gear-driven fan placed slightly toward the exhaust side of the motor. There should be an automatic oiling system, and the oil should be pumped through the hollow crankshaft and up the connecting rods to the wristpins, with a reservoir in the crankcase allowing splash for the camshaft and the main crankshaft bearings. Special arrangements should be made for cleaning, replenishing and taking care of the system.

The clutch should be of the multiple disc type, having 61 plates running in oil, and with automatic adjustment. The plates should be made of bronze and steel. A four-speed transmission with direct drive on the fourth speed has proven satisfactory. Special attention should be paid to the accessibility for the examination of the clutch and transmission. Straight-line drive should be used when the car is loaded, and there should be two universal joints inclosed in dust-proof aluminum casings. The differential should be floating, the case being made of pressed steel and strongly trussed. Adjustable radius rods and a torsion tube should be used to strengthen the construction. A trussed channel-steel, drop-forged frame should be employed, together with an I-beam axle in front having a tie-rod behind and above it. Annular bearings should be used in all wheels, and also in the differential, transmission, clutch and clutch-thrust. The front springs should be long and wide, of the semi-elliptic type, while the rear springs should be three-quarter elliptic. Shock absorbers should be used on all springs. Large expanding and contracting brakes with equalizers should be put on the rear hubs. They should be 18 inches in diameter by 3 inches wide. Steering should be irreversible with simple adjustment, and should be accessible for oiling and inspection. Spark and throttle levers should be located on a 20-inch corrugated, hard-rubber steering wheel. An accelerator and a common control for the other levers should be included. The wheelbase should be 135 inches, the tread 56 inches, the clearance 11 3-4 inches and the body a four- or five-passenger torpedo.

The equipment should be as follows: Booth demountable rims, size 36 inches by 4 1-2 inches, with two extras carried in the rear, a 30-gallon gasoline tank, also carried in the rear, with pressure gauge carried on the dash, a 2-gallon extra oil tank, top side curtains, banker windshield of the rain-vision type, nickel and black trimmings, Gray and Davis electric lights, Klaxon horn, Warner speedometer and clock, gasoline gauge, tire irons, four-cylinder tire pump, complete set of tires, tire tools, robe rail, Disco self-starter and a gradometer.

Too great emphasis cannot be laid on accessibility. Every nut and bolt should be removable with an ordinary wrench.

This car should weigh about 3,000 pounds when filled with gas, oil and water. The cost should not be over $3,000.

Greeley, Colorado. NELSON REYNOLDS.

Emergency Foot Brake

Editor THE AUTOMOBILE:

This is my ideal car for 1912. The motor should have four cylinders and should be of the monoblock type. The size of the cylinders should be 3 1-2 inches by 7 1-2 inches, with which dimensions it should develop between 20 and 30 horsepower. This would be plenty for any part of the country. The Bosch high-tension, dual magneto system should be used, also the force-feed lubricating system.

The car should be equipped with a cone clutch, leather faced, which is far superior to any other clutch. The transmission should be of the selective type with four speeds forward and reverse. The gear ratio on fourth speed should be one and one-half or two to one. The car should have shaft drive, and the front springs should be semi-elliptic, 50 inches long, while the back springs should be three-quarter elliptic.

The length of the wheelbase should be specified as 130 inches and both the front and rear tires should be 36 inches by 4 inches. The rear axle should be of the full-floating type, and the front one should be a B. & L. Castor, which in my opinion is safer and easier on the driver than the old kind. The steering should be done through an 18-inch steering wheel with spark and throttle levers on the top.

For the control, there should be two pedals and one gear-change lever. The left pedal should operate the clutch and service brake, one-third downward movement releasing the clutch and further movement applying the service brake. The right pedal should operate the emergency brake.

An electric generator, such as is used on the Cadillac, should be used for lighting and starting the motor. The rest of the equipment should be standard. The body for the car should be of the fore-door type.

This car could be manufactured for $1,250 or $1,500, according to the type of body wanted.

Saylorsburg, Pa. ROBERT L. SNYDER.

Wants No Muffler Cut-Out

Editor THE AUTOMOBILE:

I think it might be a pertinent suggestion in connection with the discussion of car improvements now going on in the columns of THE AUTOOBILE that the muffler cut-out should be omitted, because when it is fitted, it is sure to be used and this goes a long way toward making the car a nuisance on account of the abuse to which this attachment is often put by the thoughtless. P. CARR.

Schenectady, N. Y.

New Ideas Sketched in Berlin

Fancy Seats for German Cars—Other Novelties Noted There

AT the recent automobile exhibition in Berlin the Wilkening floating seat *(Schwebesitz)* attracted considerable attention. As compared with the seats usually fitted to automobiles it is supposed to represent a refinement in the way of comfort and at the same time a saving in weight and space, and perhaps in economy. It is an elaboration of a style of easy chair which years ago was much in use in Europe, generally in the form of a rocker, but its comfort in the cruder form was not considered unsurpassed. The illustration (Fig. 1) shows the present construction (German patent 221,922). The two triple leaf springs A on each side of a seat are joined at the top by a transverse bolt C around which the roller sleeve D turns on ball-bearings. At their front ends the springs carry, on flattened and slotted portions B, the cross board E, whose position may be adjusted about 3 1-2 inches by means of thumbscrews F and to which are secured the series of springs G. These are upholstered, and the woven material H is secured around them and passed slack over the roller D, the edge being stiffened with a rod I to the ends of which are attached eyelets K hooked to coiled springs L. The lower ends of these springs are attached to the scrolled upper ends of the base leaf in each of the springs A, and their strength may be chosen to suit the weight of the person occupying the seat, particularly on the occasion of long-continued journeying. To obtain the maximum of comfort the material H should be hung very slack and the hollow formed should be filled with an upholstered cushion M. A thin horsehair cushion for the back N is also advisable.

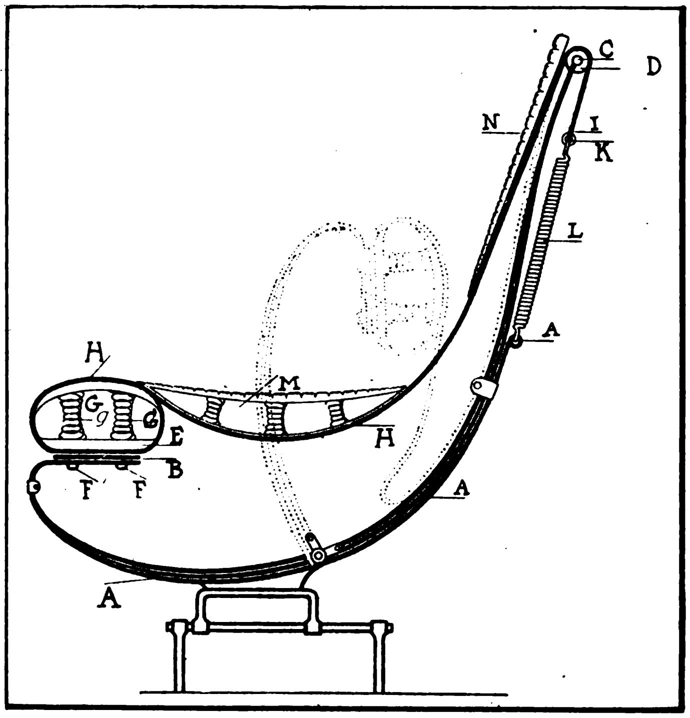

Fig. 1—German novelty in automobile seats

When to be used where it is desirable to save space if a seat is not engaged, the springs A are made with a joint which admits of the seat being folded up. For the same purpose the usual manner of mounting the seat is by means of tubular rails on which the seat may be slid forward or backward, as indicated in the illustration. The most important space economy is secured through the fact that the back of the seat has no appreciable thickness, so that the knees of a passenger in a rear seat, in the case of a car with six or seven seats, can extend forward between the springs A of the seat in front of him.—From *Zeitschrift des Mitteleuropaischen Motorwagen Vereins.*

In the 40-60-horsepower Renault car shown at Berlin a small hinged cover gives very convenient access to the universal-joint on the drive shaft for purposes of inspection and lubrication, as shown in Fig. 2, and immediately in front of this cover a small differential gear is placed inside of the universal-joint housing, forming a part of the cross shaft from which the rear wheel brakes are actuated.

It is not necessary to remove the main cover plate on top of the gear box in the 13-30-horsepower Lorraine-Dietrich car in order to replenish its supply of grease. A small cap secured with an easily undone bayonet joint, as shown in Fig. 3, can be removed for this purpose, when only one of the footboards is raised.

The water pump and the ventilator fan work on the same shaft, both driven by gear from the camshaft, in the 17-40-horsepower Dixi car, as shown in Fig. 4, and the pump can be removed by undoing a few screwbolts. The fan has only two blades, in aeroplane propellers.—From *Automobilwelt*, November 22.

Keeping Cooling Water from Freezing

AMONG the apparent paradoxes of automobiling the use of anti-freezing solutions holds a prominent place. The same motorist who is troubled in summer by the problem of cooling his water to a sufficient degree, so as to relieve the cylinder walls of the surplus heat which cannot be utilized, is faced in winter by the alternative of either using a specially mixed cooling solution or run the risk that the cooling water should grow too cold to be of use. But there is really no paradox at all. In either case the proposition is to keep up the flow of a liquid cooling medium through the cylinder jackets and to remove by means of the liquid just enough heat to keep the walls at the most advantageous temperature.

To prevent the freezing of the cooling water, a number of chemicals have been proposed to be mixed with the water. The prescriptions recommended and used are of varying value, and their worth is determined by three conditions:

1. The freezing point of the mixture should be low enough to insure the liquid remaining in that state at all temperatures encountered in a given climate.

2. The boiling point of the mixture should be as near to that of water (212 degrees Fahrenheit) as possible, to give an approximately equal cooling effect.

3. The use of the mixture should bring about the least possible chance of incrustation or formation of scale in the cylinder jackets.

As to the various anti-freezing solutions known and used at this time, they are chloride of calcium, chloride of sodium (salt), denatured alcohol, glycerine and sugar. By considering each of these materials as to how they fulfill the conditions outlined above little difficulty will be found in settling upon the anti-freezing solution best adapted to the requirements of the motorist.

Before considering these various chemicals and their effects upon the cooling-water of an engine it will be well to remember that the principle of using as pure water as possible, which every autoist strictly adheres to in his summer practice, should not be violated to any large extent in winter. Now, in summer everybody is eager to use perfectly pure water, and since distilled water is too expensive to use for the purpose, rain water is in great demand and used wherever it may be had. If this is not the case, a cautious motorist will use water which has been boiled and thus made soft. Soft water contains no calcium and magnesium salts in suspension, as rain water contains only what it had a chance to dissolve on its fall through the air, *i. e.*, a trace of carbon dioxide, and by boiling water the calcium and magnesium bicarbonates contained in it become insoluble and settle at the bottom of the vessel as a fine powder. Whenever water containing calcium and magnesia salts and carbon dioxide is boiled, the insoluble carbonates of lime and magnesia are formed, and if large quantities of these materials are present, they will lead to the formation of a scale.

A simple test to show whether water is soft or hard is to wash one's hands in a sample of the water in question. If it is hard, it will be next to impossible to produce foam with soap, while soft water will give plenty of clean foam.

Chloride of calcium reduces the freezing point of water considerably, as may be seen by referring to the accompanying table 1. The boiling point of water is raised by mixing chloride with it, and it may be said, in general, that the lower the freezing point of a watery solution of a material the higher is the boiling temperature of the solution. In dissolving the material absorbs large quantities of heat and thereby lowers the freezing temperature of water. If the water is transformed into steam, the salt dissolved in it is again transformed to the solid state and, giving off thereby the amount of heat formerly absorbed, raises the boiling point of the water correspondingly. Thus the cylinder walls are permitted to reach a much higher temperature before the water is evaporated, and while such a temperature, if it is kept up, reduces engine efficiency, a good radiator will keep the water from evaporating to a perceptible degree. Chloride of calcium will not corrode the cylinder nor jacket walls, unless it reacts acidic, in which case its solution reddens blue litmus paper. But, like most other salts, chloride will do harm to the radiator by acting as an electrolyte and gradually dissolving portions of the solder elements. Although the general belief is in opposition to the statement, the fact is that calcium chloride causes a formation of scale in the jackets, if it is used for some time. The reason therefor is the small carbon dioxide content of the water, which brings about the formation of carbonate of lime. Even if pure water is used to make the solution, the carbon dioxide will find its way into it and be dissolved by it in course of time. It is not so very improbable that some carbon dioxide, which has a very fine molecular structure, leaks through the pores of the cylinder walls, by-and-by enriching the carbonic-acid content of the water and later on leading to scale formation.

If scale is to be removed from the jacket spaces, this may be done by either mechanical or chemical means. In the first case, the jackets are taken off the cylinder, and scale scraped off them, taking care that the jacket and cylinder walls are not damaged by too violent blows. If the scale is to be gotten off in a chemical way, the jackets should be filled with dilute muriatic acid. But if this is done the acid should be left in the jacket spaces no longer than is necessary to dissolve the scale, as corrosion of the metal surfaces will be the result of this practice.

Scale formation is prevented by the use of common salt (sodium chloride) instead of the calcium compound. The sodium salt is very similar in its behavior to the calcium chloride, but the normal product of the market never reacts acidic, so that there is practically no chance of its corroding the jacket surfaces. Nor will it under any circumstances lead to scale formation, since all sodium salts are soluble in water. Even if the water should evaporate and the salt be deposited in a solid form, it will dissolve as soon as water is again admitted to it. As to its freezing efficiency, it is not quite as good as calcium chloride, but will serve almost as well and fill every need despite the inclemencies of winter in any locality of the temperate zones.

TABLE I.—FREEZING TEMPERATURES OF CALCIUM AND SODIUM CHLORIDE SOLUTIONS OF VARIOUS CONCENTRATIONS

Contents of Compound in Water in per Cent.	Freezing Temp. Cent. Sodium Chlor.	Freezing Temp. Cent. Calcium Chlor.
5	— 3.8	— 2.5
10	— 7.4	— 5.6
12	— 8.9	— 7.0
15	—11.0	— 9.6
20	—14.4	—14.8
25	—17.7	—22.1
30	—20.4	

The principal advantages of liquid anti-freezing mediums are that they leave no residues if the water evaporates, and that they cannot corrode any metal parts of the circulation system. The virtues of alcohol dissolved in water for antifreezing purposes are not to be denied. Denatured alcohol, and sometimes wood alcohol, is used for this purpose and the antithermal values of various water-alcohol mixtures are given in the following table, the values being, however, only approximate.

TABLE 2.—FREEZING POINTS OF ALCOHOL-WATER SOLUTIONS OF VARIOUS CONCENTRATIONS

Quarts of Alcohol per Gal. Water	Alcohol Content in per Cent.	Freezing Temp. Deg. Fahren.
1	20	10
1½	30	—5
2½	40	—20
4	50	—35

The trouble with alcohol is that it evaporates more rapidly than water, so that after running the motor on an alcohol-water cooling solution for some weeks, unless the radiator is perfectly tight, most of the alcohol will have disappeared. To make sure that the qualities of the alcohol still warrant its use, it should be tested for its density from time to time. Some very handy instruments are available in the market, of which mention should be made of the so-called Freezometer, which can be procured for a small sum.

Another disadvantage of alcohol is that the denatured product has been put into that condition by mixing with it such materials as pyridine, which in no way go to improve the smell of the oft-abused commodity. At the same time it should be carried in mind that alcohol is combustible, and if it is not carefully watched, might cause considerable trouble in this direction.

Glycerine has a very low freezing-point and boils at a high temperature, both of which features would tend to make it a desirable anti-freezing substance. If, however, the commercial, not the chemically pure, product is used, for the sake of its low price, the fatty acids contained in it will spell disaster to the tender metallic portions of the cooling system, especially the radiator. On the other hand, pure glycerine is very expensive, and rapidly dissolves all impurities it comes in touch with, so that pretty soon the cooling system of the motor will be bound to suffer if glycerine is introduced. It has the one advantage in common with salt solutions that it does not evaporate like alcohol, and in refilling the cooling system only pure water has to be added.

Some experiments have been made as to the usefulness of lubricating oil as a cooling medium, but they have not been successful. Oil has a low specific heat, and while its freezing point is low enough to insure the oil remaining liquid at all practical temperatures, its boiling point is likewise low, so that only comparatively small quantities of heat may be carried to the radiator by a given volume of oil. Furthermore, if air is caught in the piping system, a great deal of the hot oil will be burned and the resulting odors will be found far from pleasant by the occupants of the car.

All things considered, common salt, *i. e.*, sodium chloride, may be looked upon as the cheapest and best anti-freezing chemical. Nevertheless, a great number of automobilists prefer other compounds, partly because they have to pay more for them, and partly because the foregoing statement sounds too good to be true. There are few people who understand that the commonest are the most important materials in life as well as in automobiles, and that, for instance, air and water are the most precious and effective foods, even if we cannot live on them alone like the lilies.

Calendar of Coming Events

Shows

Dec. 30-Jan. 6......Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.
Jan. 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 13-19.........Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 13-27.........Philadelphia, Annual Show, First and Third Regiment Armories, Philadelphia Automobile Trade Association.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 15-20.........Toledo, O., Annual Show, Terminal Building, Toledo Automobile Dealers' Association.
Jan. 22-27.........Rochester, N. Y., Annual Show, State Armory, Rochester Automobile Dealers' Association.
Jan. 22-27.........Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dealers' Association.
Jan. 22-27.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 22-27.........Dubuque, Iowa, Annual Show Dubuque Automobile Dealers' Association.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 27-Feb. 10....Pittsburgh, Pa., Sixth Annual Show, Automobile Dealers' Association of Pittsburgh, Inc. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 29-Feb. 3......Scranton, Pa., 13th Regiment Armory, Second Annual Show.
Feb. 1-7...........Washington, D. C., Annual Show, Convention Hall.
Feb. 3-10..........Montreal, Canada, National Show, Drill Hall, Automobile Club of Canada.
Feb. 5-10..........Buffalo, N. Y., Convention Hall, George C. Fehrman.
Feb. 5-17..........St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 12-17.........Ottawa, Ont., Howick Hall, Annual Show, Ottawa Valley Motor Car Association.
Feb. 12-17.........Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 12-19.........Dayton, O., Third Annual Show, Dayton Automobile Club.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24.........Pittsburgh, Pa., Second Annual Show, Exposition bldg., Pittsburgh Auto Show Association, Inc.
Feb. 17-24.........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Feb. 19-24.........Omaha, Neb., Seventh Annual Show, Auditorium, Omaha Automobile Show Association.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 19-24.........Cincinnati, O., Annual Show, Music Hall, Cincinnati Automobile Dealers' Association.
Feb. 20-24.........Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Feb. 20-28.........Baltimore, Md., Annual Show, Baltimore Automobile Dealers' Association.
Feb. 21-24.........Louisville, Ky., Fifth Annual Show, First Regiment Armory, Louisville Automobile Dealers' Association.
Feb. 21-28.........Toronto, Ont., Annual Show, The Armouries, Toronto Automobile Trade Association.
Feb. 24-March 2...Brooklyn, N. Y., Twenty-third Regiment Armory, Annual Show, Brooklyn Motor Vehicle Dealers' Association.
Feb. 26-Mar. 2.....Elmira, N. Y., Second Annual Show, Elmira Automobile Club.
Feb. 26-Mar. 2.....Paterson, N. J., Annual Show, Fifth Regt. Armory, Paterson Automobile Trade Association.
Feb. 28-Mar. 2.....Davenport, Iowa, Annual Show, Davenport Automobile Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.
March 4-9.........Denver, Col., Auditorium, Annual Show.
March 4-9.........Denver, Col., Annual Show, Auditorium, Motor Field.
March 6-9.........Tiffin, O., Second Annual Show, The *Advertiser*.
March 12-16.......Syracuse, N. Y., Fourth Annual Show, State Armory, Syracuse Automobile Dealers' Association.

Meetings, Etc.

Dec. 20...........New York City, Waldorf-Astoria, Annual Banquet of the Automobile Club of America.
Jan. 18-20........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Dec. 25-26........Los Angeles, Cal., Track Races, Motordrome.

THE AUTOMOBILE

Vol. XXV Thursday, December 21, 1911 No. 25

THE CLASS JOURNAL COMPANY

H. M. SWETLAND, President

CONDE NAST, Vice-President and General Manager

E. M. COREY, Secretary and Treasurer

Prolific Patent Litigation

"I WOULD readily put over $50,000 into the manufacture of the device, but it is so easy to make that we would enter immediately into a prolonged ordeal of patent litigation which would eat up all of our profits." This statement, recently made by the holder of a basic patent on a new device in connection with the winter use of automobiles, strikes a chord in the present condition of the automobile industry which is not at all a pleasant one; namely, the entire disregard of patent rights in conjunction with many car articles. It is only within the last few years that what might be termed an acute situation has arisen in this connection. At present there are hosts of cases pending in the courts, which cases are based on patents that in some cases are comparatively unknown. These patents have been acquired within the last few years and have been held quietly until the holders had decided whether the infringements were sufficiently general to demand prosecution. With several of these patents the owners cannot but have realized that their claims were not broad enough to cover what they looked upon as infringements, but they nevertheless have prosecuted several small makers, knowing that often a patent case is decided by the size of the available litigation fund. In other instances the exact opposite is the case: the patent owners have had specially broad claims, claims that nearly every infringer knew would certainly be upheld, but the infringers figured that the case would occupy many years in court and during that time there would be ample opportunity to get all they desired out of the situation. It is unfortunate that patent litigation is and has been so slow. Often the life of a patent has almost expired before its validity is settled. There should not be any necessity for this. It should not require 15 years to determine whether there has been any interference, and it should not require 15 years for a few judges to settle what they consider the actual meaning of the claims and construction of a patent.

A probable solution could be had in the establishment of a special patent court in which the judges on the bench would be particularly qualified to readily decide on the merits of mechanical claims and constructions. The necessity for such can be seen in the fact that in some cases judges have reversed their own decisions of a few months or years previous. Apparently the only reason for such conditions is lack of familiarity with the principles of engineering underlying the cases at issue. To settle many intricate patent litigation suits has called for specially clear insight into matters technical, and it is scarcely expected that different judges should be able to act with dispatch in such cases.

* * *

Shows and Contests Pay

France has relented: She is going back to the annual show and she is going back, if she can, to the Grand Prix road race. Both are for 1912. It is only a few years ago that the French makers stood up and said to the remainder of the automobile world that they did not need an annual show; that it was only a bill of expense to them; and that, by inference, their products were so far in advance of those of other countries that special exhibition of them was not needed more than once in two years. The Englishman, who was caught napping in the early days of the automobile, saw the lapsing of France and jumped into the gap with his international Olympia and got away with the goods. The Frenchman has at last realized the situation and now wants the annual show. Next fall there will be the rival displays on either side of the channel. What the outcome will be is not of particular interest on this side of the Atlantic just at present, as it will not affect either the New York or Chicago shows whether there are two big shows in Europe or if there are half a dozen. There is one big point that does interest American automobile builders, however, and that is that a show is a necessary factor in the industry today. During the last 6 or 7 years there have been a few makers who felt that they did not have to go to shows to sell their product. Several have seen the error of their ways and are getting into the show circle this year. Many makers who have done good business for the last couple of seasons have been talking about the futility of shows, but these people had better beware. The experience of the Frenchman is a good one to ponder over and to take lessons from. This is an age of publicity and it does not call for many consecutive months of obscurity to let a maker of renown fall out of public approval. The shows are great publicity features; they focus the attention of the entire nation on the automobile, and although the sales may not be as large as desired the results cannot be counted by actual sales made. The results of show work extend through the following 6 months of selling. The maker who exhibits may not know this so well as the maker who does not exhibit. During the show period there is a mass of missionary work done. The selling seed has been dropped into soil of unexpected fertility and the harvest has always been a good one. The shows and contests constitute excellent vehicles for keeping the automobile in the public eye and both should be encouraged and sustained. There are many examples of foolish prodigality during show weeks. This can be eliminated and the value of the show not reduced in the least.

All Jersey Working for Sane Law

THE following notice as to the legal situation in New Jersey has been issued by the joint legislative committee representing all the warring factions of New Jersey motordom.

All motorists in New Jersey are vitally interested in automobile legislation that has for its principle "that motorists from other states desiring to tour in New Jersey shall be permitted to do so for a limited period of time without requiring them to take out registration or sign power of attorney, when they have been properly registered in their own state, provided that state extends the same privileges to the motorists of New Jersey," and they will remember the strenuous efforts that were brought forth last year to have the Legislature pass a reciprocity bill and the fact that it was defeated in the Senate by only one vote, the vote being a tie.

It should be a great satisfaction for them to now learn that through organization special efforts are being put forth this year to secure the legislation that they all so much desire, and they will no doubt be interested to learn that the principal and largest automobile organizations of the state, representing every shade of opinion among organized motorists, both from the trade as well as owners of automobiles, have gotten together on this subject, and there has been a joint committee appointed.

This committee is known as the Joint Legislative Committee of the Automobilists of New Jersey, and has full power to take charge of the proposed automobile legislation this Winter in the interests of all motorists, irrespective of club affiliations, and they have every hope that the labors of this committee will be crowned with success, and that the present unfavorable attitude of the New Jersey law in regard to visiting motorists will be done away with and that we shall have reciprocity between the various states.

The Joint Legislative Committee of the Automobilists of New Jersey is composed of five representatives from the New Jersey Automobile Trade Association, five representatives from the Associated Automobile Clubs of New Jersey, and five representatives from the New Jersey Automobile and Motor Clubs.

The representatives from the New Jersey Automobile Trade Association are as follows:

Geo. Blakeslee, Geo. H. Smith, Louis Fitzgerald, W. H. Ellis, Geo. Paddock.

Those from the Associated Automobile Clubs of New Jersey are as follows:

W. Eugene Turton, Jos. H. Wood, W. Clive Crosby, J. H. Edwards, Geo. Post.

Those from the New Jersey Automobile and Motor Club are as follows:

Richard C. Jenkinson, G. O. Groebe, Ira Kipp, Jr., Horace P. Cook, Melville A. Carpenter.

If New Jersey is not brought back into the automobile "union" this Winter, it will not be due to the failure of the motorists of this state presenting a united and determined effort or the failure of an earnest and hard working representation.

Michigan Law to Be Sharply Tested

DETROIT, MICH., Dec. 18—The constitutionality of the Michigan law which holds the owner of a motor car responsible for damage done by his machine unless he can prove that the machine had been stolen from him, was attacked in the Federal court here last week, in the suit brought by John Parrott, of Mt. Clemens, against the Metzger Motor Car Co., arising out of an accident on the Gratiot road some time ago. Judge Angell strongly intimated that he believed the point well taken, but preferred to leave the determination of the question to a higher court. Accordingly he permitted the case to go to the jury, which brought in a verdict for $1,843 against the Metzger Co. It is certain that the case will be appealed.

Parrott was driving a team from Detroit to Mt. Clemens on the Gratiot road, when an automobile, owned by the Metzger Motor Car Co., and driven by one of its employees, crashed into the farmer's cart, overturning it, killing one of the horses and injuring Parrott. The company admitted ownership of the car and lack of negligence on the part of Parrott, but denied responsibility for the accident on the ground that the driver of the car was using it without permission. On this theory, Attorney Brennan, representing the Metzger Co., moved the court to direct a verdict of no cause for action, but as this was the first time the constitutionality of such an act had been questioned he was unable to find any decisions covering the point.

Judge Angell acknowledged that, in overruling the motion, he acted with some hesitancy because the motor car seemed to be legislated against in this instance.

"The motor car is not like dynamite or nitro-glycerine," said the court. "We who live in Detroit are familiar enough with it to know that it has no inherent qualities of danger. The same degree of responsibility does not attach to the owner of a horse and wagon, and it seems unfair to place the owner of an automobile in a special class."

In his argument to the court, Attorney Brennan said:

"It is class legislation when a man, because he has money enough to purchase an automobile instead of a horse and buggy, is put in a separate class with heavier responsibilities. The law of Michigan which makes an automobile owner responsible for damage done by his machine unless he can prove that it was stolen and can prove the intent of the thief, puts every automobile owner at the mercy of the hoodlums of the street who 'borrow good people's machines to go joy-riding."

Judge Spier, of Mt. Clemens, who appeared for the plaintiff, defended the law on the ground that the state has power to make police regulations for the protection of citizens against careless and reckless driving of motor cars. If persons sustaining damage were unable to recover from the owners of motor cars they would be unable to get redress from any source, he declared.

It is understood that the Metzger Co. is determined to take the case to the Supreme Court of the United States, if necessary. The first appeal will be to the Circuit Court of Appeals at Cincinnati.

Jersey Mayors to Abolish Death Traps

Grade crossings in New Jersey are to be abolished, root and branch, if the purpose of the mayors of various cities in the State is carried out. The mayors will form an organization Jan. 6, at Trenton. A preliminary meeting was held Tuesday at East Orange where the determination to form an association was crystallized. Under the plan it is intended to abolish grade crossings in counties of the first class by July, 1914, and throughout the State by 1920.

A bill will be drafted for presentation to the coming legislative session.

MANY TOO LATE—Inquiries are being received daily regarding the reservation of space at the Madison Square Garden show. This is one of the cases where the early birds have made away with the worm as the space has long since been completely closed out.

Luncheon given by Hotel Breslin management to exhibitors at the Garden Show

News of Shows, National and Local

WHEN Madison Square Garden throws wide its doors for its last function—the Twelfth National Automobile Show on January 6—hundreds of motoring enthusiasts will have opened to them the most magnificent and biggest automobile display ever seen in the nationally famous building.

For 1912 the pictorial idea is that of a mammoth Oriental garden. The color scheme is to be crimson and gold with smatterings here and there of blue, green and white.

The exhibition spaces on the main floor, elevated platform and balcony will be carpeted with a specially woven fabric of green hue giving the appearance of the cars reposing on grass. Entering from the foyer the visitor will be confronted by a huge fountain. Back of the fountain, in the center, is a statue representing The Motor Era. The water from the fountain will be electrically radiant, made so by iridescent and hidden electric bulbs. All about the fountain are eight allegorical figures 10 feet high arched by garlands of natural flowers. Six bay trees are recessed in the front of the fountain. Beyond this fountain will extend the main display space.

The plan of having the elevated platform and balcony above the arena boxes project over the main floor and of covering the high rear seats so as to make a sort of mezzanine floor will be repeated.

Poster for the Garden Show

A novel feature of the decoration this year will be the treatment of the ceiling which will have the appearance of an inverted oriental rug with rich coloring and treatment. This gigantic painting will cover the steel girders of the ceiling and will gracefully hang down the sides. The total weight of the canopy is more than 3 tons. The figure in the center panel of the painting represents the triumph of the industry. The panel measures 100 by 200 feet.

Plans for the new arena, which in future will augment the space available for show purposes of the Grand Central Palace, will be completed Saturday night and will be submitted to the New York Central Railroad and the management of the palace immediately afterward.

Several changes have been made in the draft first prepared and the present plans contemplate a building more commodious in every way than the one originally considered. Dates for actual commencement of work will be announced in the near future.

Invitations are being prepared by the management of the N. A. A. M. show at the Palace for all the exhibitors who will show at the Garden, and on opening night it is expected that the Board of Trade exhibitors will attend in a body.

Tuesday and Thursday have been designated during show week as society nights and special preparations have been made to arrange suitable programs.

A Score of Exhibitors at the Salon

The twenty different makes which will be exhibited at the Importers' Automobile Salon include every foreign car which has achieved distinction either in this country or abroad. The English Daimler, Panhard, Mercedes and Minerva exhibits will include models having Silent Knight sliding sleeve-valve motors. while those of the Itala and Darracq will have models with new rotary valve motors. The latter are entirely new to the automobile public in this country and will attract much attention from the visitors to the Salon.

It is perhaps the magnificent bodies, particularly those of the inclosed type, mounted on the various chassis exhibited at the Salon, which are of the greatest interest. They are the products of the well-known body builders of Europe and America, whose names are synonymous with ultra-luxuriousness.

New Cars to Make Their Bow at Detroit

DETROIT, MICH., Dec. 18—Detroit's Eleventh Annual Automobile Show, to be held in the Wayne Gardens and the new Annex, 108 feet wide by 165 feet long, promises to be without any doubt America's leading local show and the largest local exhibition in the country if not the most important. The trade of Detroit accepted readily the proposition of the D. A. D. A. to construct this building providing they would take space.

It is known generally that a great many of the Detroit exhibitors will display for the first time new cars, which they will not have ready for the New York show; but which will be completed in time for Detroit and Chicago and later shows.

Change of Plans at Philadelphia

PHILADELPHIA, Dec. 18—A radical departure in the plans for the second week of the local Automobile Show has been announced, necessitated by reason of the large number of applications for commercial vehicle space. Originally being the intention to confine the motor truck display to the Third Regiment Armory, during the second week, January 22 to 27 inclusive, the revised plans comprehend the exhibition of commercial cars at the First Regiment Armory, in addition; thus the show in the latter building, instead of being devoted exclusively to electrics, will consist of electric pleasure cars and equipment and of commercial cars.

National Will Show in Breslin Lobby

Out of a field of twenty-one, W. C. Poertner, of the Poertner Motor Car Co., handling the National line in the metropolis, drew the lucky number at the annual luncheon tendered to the automobile trade in New York by the management of the Hotel Breslin, and as a result the National company will have the privilege of exhibiting one of its models in the lobby of the hotel during the coming show.

S. A. Miles presided and the speakers included: Alfred Reeves, H. A. Bonnell, A. G. Batchelder, M. L. Downs and several others.

News of Other Local Shows

BALTIMORE, MD., Dec. 16—The Baltimore show will be held February 20 to 28, inclusive, under the joint auspices of the Automobile Club of Maryland and the Baltimore Dealers' Association. The Fifth Regiment Armory has again been secured. Commercial cars will be shown on the last three days of the show exclusively, the first five days being devoted to pleasure vehicles. Dealers in accessories will have their exhibits on hand on all of the eight nights of the show. The joint committee will consist of Dr. H. M. Rowe, president of both the Club and Dealers' Association, chairman; Joel G. Nassauer, Thomas G. Young, H. K. Luzius and John B. Bridges, representing the club and R. J. W. Hamill, A. S. Zell, F. S. Blven and W. L. Duck, representing the dealers.

SIOUX CITY, IA.—The annual automobile show under the auspices of the Sioux City Automobile Dealers' Association, will be held in the latter part of February, or early in March. As the Omaha show is from February 19 to 24, and the Des Moines show, March 4 to 9, it is planned to hold the Sioux City show between these shows. C. M. Wyckoff was re-elected as president of the association. The other officers are: H. A. Wetmore, vice-president; Ralph Wigton, secretary; F. H. Reid, secretary; executive committee, H. B. Groves, H. A. Wetmore, and S. C. Douglas.

TOLEDO, O., Dec. 18—The approaching Toledo Automobile Show promises to eclipse anything of the kind ever undertaken here. Exhibitors are enthusiastic, and all available space will be taken by the concerns handling cars and accessories. An extensive advertising campaign throughout northwestern Ohio will be inaugurated, and indications for success are of the brightest. The Terminal building, which was selected as a location for the show, is being prepared and beautified, and nothing will be left undone by the managers of the exhibition to attract the attention of the public generally.

DAYTON, O., Dec. 15—Committees representing the Dayton Automobile Club and the automobile dealers of the city have selected Elmer C. Redelle, manager of the Dayton baseball team, to take charge of the annual automobile show, which will be held February 12-19. The club committee is composed of William Stroup, Walter Kidder, E. A. Deeds and Walter Kuhns. The dealers are represented by George L. Baker, William H. Yeazell, Earl Hosler, George W. Shroyer and G. G. Peckham. Plans for the show will be begun at once. The show will be the third held in Dayton.

CLEVELAND, O.—Automobile manufacturers and dealers and the Cleveland Automobile Club will work jointly this year toward the success of the Cleveland automobile show to be held in Central Armory, February 17 to 24, inclusive. Frank W. Philips resigned as chairman of the show committee recently. H. M. Adams was chosen to fill the vacancy. Fred H. Caley, secretary of the Cleveland Automobile Club, was named as manager of the show by the show committee.

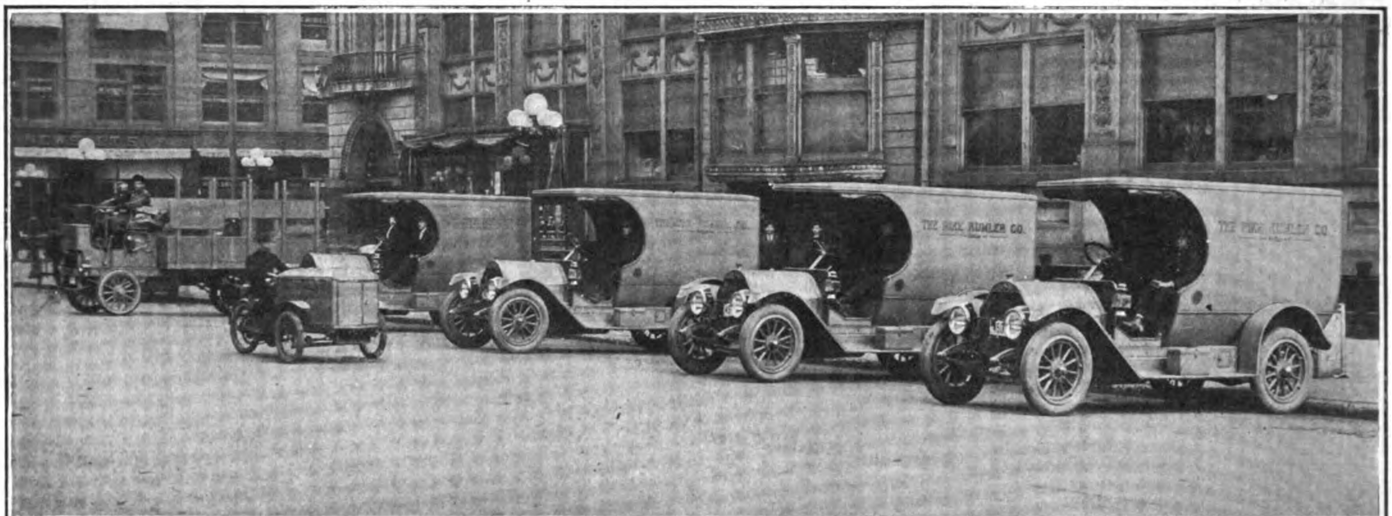
SYRACUSE, N. Y., Dec. 16—The Automobile Dealers' Association is perfecting plans for the third annual automobile show in the Armory in March. An effort is being made to find a place of exhibition for trucks and accessories, because of the heavy demands for space made by manufacturers of passenger cars.

MILWAUKEE, WIS., Dec. 18—Space for the fourth annual Milwaukee show, to be given by the Milwaukee Automobile Dealers' Association in the Auditorium, Jan. 13 to 19 inclusive, was allotted last week and the results show that there will be seventy pleasure car exhibits, thirty of commercial cars and fifty-one of accessories.

DES MOINES, IA.—Des Moines had a small-sized automobile show last week as an adjunct of the state convention and show of the Iowa Implement Dealers' Association, at the Coliseum. Many of the dealers showed automobiles along with their implements.

BUFFALO, Dec. 18—Space in the second automobile show of the Buffalo season will be alloted December 29. The show will be held in Convention Hall, February 5-10. The enterprise is under the management of George C. Fehrman.

DUBUQUE, IA., Dec. 18—Dubuque automobile dealers have formed an association for mutual protection. They also propose to hold an automobile show during the week commencing January 22, 1912.



NEWS of the WEEK CONDENSED

Auto delivery equipment of a Dayton, Ohio, department store, all supplied with Aplco Model A3 electric lighting system

DETROIT, MICH.—The Wolverine Motor Supplies Co. has increased its capital from $10,000 to $25,000.

MONTREAL, QUE.—The Motor Import Co., Ltd., has taken the agency for the Hupmobile in this city.

CHARLOTTE, N. C.—J. D. and M. W. Woodsides are arranging to build an automobile repair shop and garage.

WASHINGTON, D. C.—Emerson & Orme, 1407 H street, N. W., have added the Fiat to their line, which consists of the Apperson and Detroit Electric.

LINCOLN, NEB.—H. E. Mason, formerly with the Shamp Implement Co., has purchased an interest in the Sidles Motor Co., succeeding G. E. Swope as manager.

WASHINGTON, D. C.—C. Cassard Schroth, agent for the Stearns, has taken quarters with the Wilson Co., 918 Fourteenth street, N. W. The latter handles the Cole and Krit.

SPOKANE, WASH.—The Mitchell automobile will be represented by the Metropolitan Motor Car Co. Manager Harry Bell recently announced the relinquishment of the Marion.

NEW YORK CITY—The Schildwachter Carriage Co., 128th street and Park avenue, has taken the eastern agency for the Sternberg truck. The company also handles the McIntyre power wagon.

AKRON, O.—The B. F. Goodrich Co. announces the opening of three new branches in California, at Fresno, Oakland and Sacramento, these being in charge respectively, of the following managers: R. W. Peters, H. S. Smith and H. W. Schoenlaub.

ATLANTA, GA.—The Southern branch of the White Co. has followed the trend of the times and opened a show room on Peachtree street. The present garage and machine shop on Marietta street will be used as before.

LOUISVILLE, KY.—F. E. Van Patton has been selected as the manager of the new branch of the Ford Motor Co. Before coming to this city Mr. Van Patton was assistant manager of the Cleveland branch of the Ford Motor Co.

BOSTON, MASS.—The Matheson Co. has secured the new building erected for the Alco and Stoddard-Dayton on Commonwealth avenue recently, and which was vacated when those two cars were changed from agencies to branches.

PHILADELPHIA—The Gomery-Schwartz Motor Car Co., local distributor of the Hudson, has removed from the southwest corner of Broad and Callowhill streets to larger and more modern quarters at Nos. 253-255 North Broad street.

MILWAUKEE, WIS.—T. A. Brinn, formerly head of the motor assembly department of the Wisconsin Motor Manufacturing Co., has taken a similar position with the Beaver Manufacturing Co. The Beaver company has been reorganized recently by General Manager Lewis.

WASHINGTON, D. C.—E. C. Bull has resigned as manager of the Pope Automobile Co., agents for the Pope-Hartford and Marathon, to accept a position with the New York branch of the Lozier Motor Co. He has been succeeded by H. N. Dewitt.

TACOMA, WASH.—The past week there congregated in Tacoma all the Jackson automobile dealers of the Northwest, who came to view the latest models turned out by the Jackson Automobile Co. They were the guests of Northwest Manager F. E. Cady.

DENVER, COL.—The Denver Motor Club has leased Overland Park for 5 years. The organization will have one of the best equipments in the country including all the conveniences and luxuries of a country club and a race track which will be banked and prepared for speeding.

PHILADELPHIA—The Streator Motor Car Co., of Streator, Ill., manufacturer of the Halladay car, has opened an Eastern distributing sales agency at Fifteenth and Oxford streets in this city. The agency's territory will comprise Pennsylvania, New Jersey, Delaware and Maryland.

MILWAUKEE, WIS.—The KisselKar Co., representing the Kissel Motor Car Co., of Hartford, Wis., in Wisconsin and several other states, has moved into its new garage and salesroom building at 176-178-180 Seventh street. The new building cost $45,000. Frank J. Edwards is manager of the company.

MILWAUKEE, WIS.—Raymond C. Agner, of Burlington, Wis., inventor of an oil and grease gun and other motor car specialties, tools, etc., has been granted patents on an adjustable spark plug wrench, to be marketed under the trade mark of Simplex. It will be manufactured by Mr. Agner's company at Burlington.

MILWAUKEE, WIS.—C. A. Hamilton, for six years vice-president and manager of the Wisconsin Engine Co., of Corliss, Wis., has resigned to become associated with the Lavigne Gear Co. of Milwaukee, a reorganization of the Lavigne Gear Co. of Detroit, which recently established a plant at Corliss to manufacture steering gears and has taken quarters in Milwaukee to be used as general offices.

REDMOND, ORE.—Powers & Hess are installing an automobile repair shop here.

MONTREAL, QUE.—The Pope-Hartford Co. of Canada will handle the Pope-Hartford in this city.

RIPON, WIS.—Edward Bobzin, proprietor of the Bobzin Garage, has taken the agency for the Buick in this territory.

NEW YORK CITY—The J. I. Case Co., of Racine, Wis., has opened a branch at 1850 Broadway. O. A. Lewellen is in charge.

TORONTO, ONT.—The McLaughlin Carriage Co. of this city are agents for the Fiat car and for the Rauch & Lang electric.

NEW YORK CITY—H. E. Steinbock has severed his connection with the engineering department of the United States Motor Co.

ERIE, PA.—G. H. Henry has bought out the interest of his partner, E. A. Semmence, in the Hupmobile Sales Co., of 1319 Peach street.

KANSAS CITY, MO.—A new brick garage is to be erected at 1713 McGee street by McGiloray & Bowling. The building will cost $4,000.

MONTREAL, QUE.—E. Major, 37 St. Catherine street West, has been appointed Canadian representative of the Delaunay-Belleville car.

MONTREAL, QUE.—Automobile Francais is the name of the company which has taken the agency for the Renault, Berliet and Gregoire cars.

CINCINNATI, O.—William Duffy, formerly with the Motor Supply Co., of this city, has associated himself with the Fisk Rubber Tire Co., 816 Main street.

MONCTON, N. B.—The International Automobile Co. of Moncton has been incorporated to deal in automobiles. The company is capitalized at $50,000.

MONTREAL, QUE.—The National Motor Co. of Canada, Ltd., has changed its name to the Windsor Auto Garage & Engineering Co. and will devote itself entirely to the garage business.

CINCINNATI, O.—The Chas. Behlen Sons Co., distributor of the Locomobile and the Detroit Electric, is making extensive improvements in its showroom at Fifteenth and Vine streets.

FREMONT, O.—The Lauth-Juergens Co., of this city, has appointed the following agents: Mutual Auto Co., Duluth, Minn.; P. A. Brink, Los Angeles, Cal., and A. S. Lascelles & Co., New York.

PROVIDENCE, R. I.—The 1912 Alco limousines are equipped with marine windows which, beside relieving the car's continuity of line, enable the driver to obtain an unobstructed view to the rear.

CINCINNATI, O.—The first six-cylinder police patrol to leave the Packard factory was recently delivered to the local police department. The body is mounted on a standard with extra-heavy springs.

ROCHESTER, N. Y.—William Knipper, who drove a Mercer in the recent races at Savannah, Ga., has retired from the field of automobile racing and has taken the agency for the Stutz car in this territory.

WASHINGTON, D. C.—The Overland-Washington Motor Co. has been appointed agent for the Garford line of pleasure cars and trucks. Considerable territory in Virginia and Maryland has been given the new agency.

FLINT, MICH.—A. B. Hardy has resigned his position with the General Motors Co. as general manager of the Marquette Motor Co., of Saginaw, Mich., to become general manager of the Little Motor Car Co., of this city.

WILLIAMSPORT, PA.—Messrs. Weller and Davidson have organized the Central Garage of Williamsport to do a general machine shop and automobile repair business. They will handle the Matheson car in this territory.

ST. LOUIS, MO.—The Behen Automobile Equipment Co., Kingshighway and Delmar avenue, has commenced business and will handle automobile supplies and accessories. John J. Behen is president and treasurer and S. F. Behen is secretary.

DES MOINES, IA.—The Capital City Carriage Co., Des Moines, agent for the Jackson, has taken uptown quarters. This company has represented the Jackson here for several years but has always conducted the business from the factory.

NEW YORK CITY—Chas. E. Riess & Co., general eastern distributors of the Marion car, and the American-Marion Sales Co., metropolitan distributor of American and Marion cars, have moved into their new offices and salesrooms at 1896 Broadway.

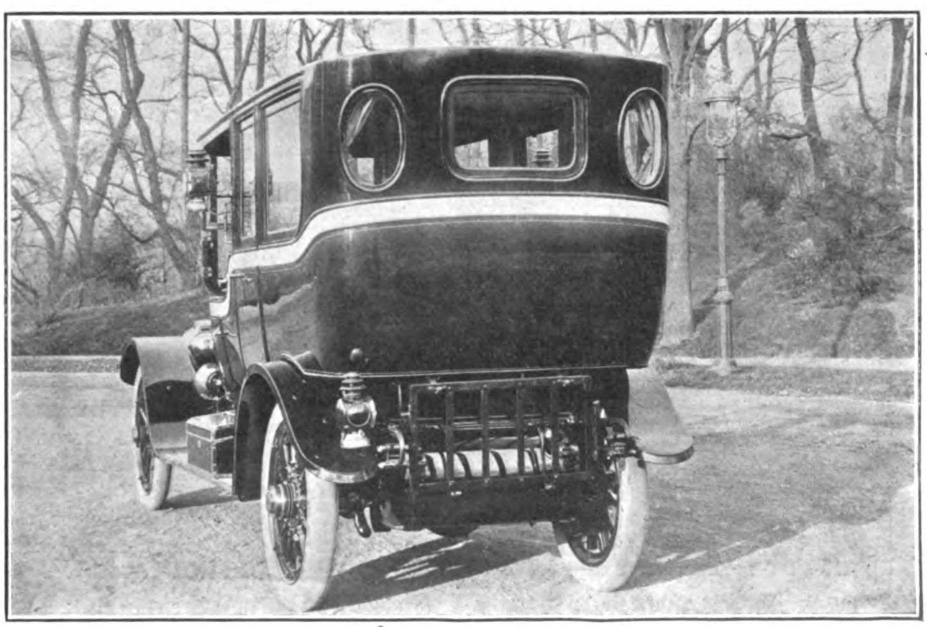
LOUISVILLE, KY.—The Ford Motor Co., of Detroit, Mich., has selected F. E. Van Patton as the manager of its new branch here. Mr. Van Patton has been connected with the company for some time as assistant manager of the Cleveland, O., branch.

STREATOR, ILL.—The Streator Motor Car Co. has appointed the following special factory representatives: L. W. Thompson, Oklahoma and part of Kansas; C. R. Reilly, part of Iowa; F. S. Van Veghten, Nebraska, and the Mound City Buggy Co., Missouri.

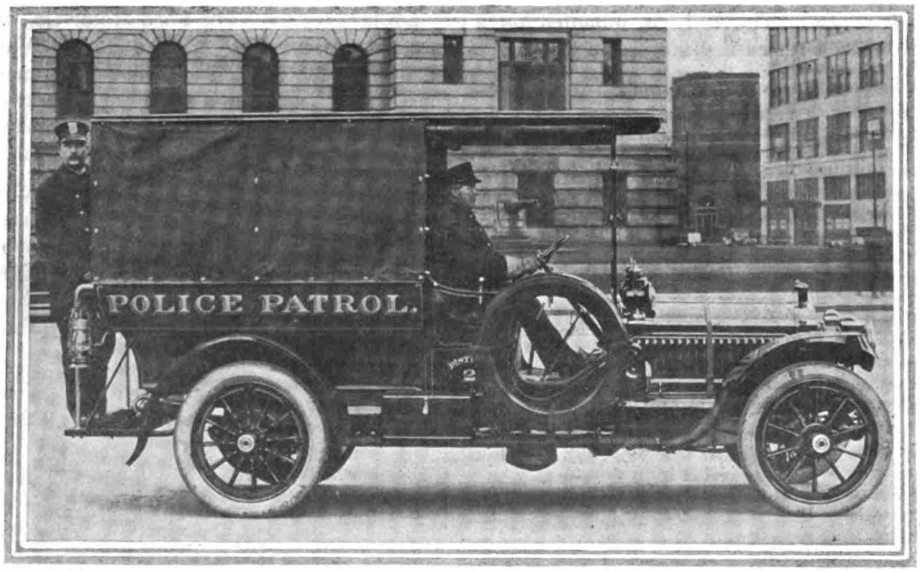
BRIDGEPORT, CONN.—Leonard W. Williams, until recently manager of the Oakland branch of the Locomobile Co. of America, has come East to become associated with the advertising department of the Locomobile company. Mr. Williams, prior to his work on the coast, was connected with the Philadelphia branch of the company.

ATLANTA, GA.—The movement to do away with horse-drawn vehicles in all the departments of Atlanta's municipal work goes steadily ahead. The latest addition to the Gate City's fleet is a White Truck for the tapping and construction department of the city waterworks. The sanitary, hospital, construction, waterworks, police and fire departments all use machines and find them much more efficient than horses.

MILWAUKEE, WIS.—The Smith-Hoppe Auto Company, state agent for the Hupp-Yeats electric and local agent for the Oakland and R. C. H., has moved to its new garage at Wisconsin and Cass streets, erected at a cost of $45,000. The Wisconsin Auto Sales Company, state representative of the National, Herreshoff, Cutting and Westcott, has also taken quarters in the new garage, which is one of the largest in point of one-floor space in the city of Milwaukee.



View of 1912 Alco limousine, showing new marine windows in rear



Packard patrol wagon now doing duty in the Cincinnati police department

AKRON, O.—D. H. Holloway, Central Savings & Trust building, has taken the local agency for the Elmore.

SYRACUSE, N. Y.—The Porter-Cable Machine Company, of this city, is working full night and day shifts to turn out Hanna self starters.

COLUMBUS, O.—F. E. Avery, central Ohio agent for the Packard, will leave in the near future for a four-months' trip through Cuba, Panama and points in the West Indias.

CAMBRIDGE, O.—Otho Prince has secured a patent on an automobile fender which it is claimed is an improvement over the present fenders. The fender is intended to operate automatically.

CINCINNATI, O.—W. C. Woellner has resigned as purchasing agent of the Schacht Motor Car Company to become identified with the Instantaneous Auto Starter Company, in the capacity of sales manager.

INDIANAPOLIS, IND.—The Delaware Garage has started a clearing house for second-hand automobiles. The first sale was held on December 18.

INDIANAPOLIS, IND.—W. W. Bond, for some time city sales manager for the Brewer Auto Company, has resigned and will handle the agency for the Woten electric rectifier in Cook County, Ill.

CLEVELAND, O.—Ray M. Colwell, who recently resigned as local manager of the Buick Motor Co., has incorporated the Start-O Co., with offices at 1636 Walnut avenue N. E. Mr. Colwell is the inventor of the Victor self-starter.

AKRON, O.—Despite the uncertainty of a presidential election and the unsettled conditions usually found throughout the country in such years, Akron rubber manufacturers predict that next year will be the biggest in the history of the industry.

PHILADELPHIA, PA.—The D. Walter Harper Company, who introduced the Stanley Steamer here in 1903, has been the last to give up the sale of steam cars. It will represent the Case cars, as well as the Cameron air-cooled line of pleasure and delivery models.

BARBERTON, O.—Another rubber factory is soon to start operations here. The old factory building formerly used by the Carrara Paint Company has been sold to Adam Duncan, of Akron, O., and will be turned into a reclaiming plant. Six reclaiming machines will be installed.

PROVIDENCE, R. I.—J. F. Gfrorer has been announced in charge of the service department of the American Locomotive Company. Since joining this organization Mr. Gfrorer has been engaged in special work. Mr. Gfrorer has been associated with the motor industry since 1903.

AUBURN, IND.—Companies known as the Kansas City-Auburn Company and the Omaha-Auburn Company, which will be factory sales branches of the Auburn Automobile Company, have been organized and incorporated. Each company has an authorized capitalization of $10,000.

NEW YORK CITY—Louis Hendon has been appointed assistant superintendent in the service department of the Thomas Motor Company of New York. Previously Mr. Hendon was superintendent of the Mitchell repair shop here, and more recently had charge of the Packard shop in Savannah, Ga.

DETROIT, MICH.—The position of advertising manager of the Lozier Motor Company will be filled by James M. Evans, the vacancy having been created by the appointment of C. A. Emise as sales manager, to succeed F. C. Chandler, who has been appointed general manager of the Lozier Motor Company.

OMAHA, NEB.—T. V. Graves, of Chicago, has come to Omaha to take charge of the local branch of the Goodyear Tire Company. He has temporary quarters with the Powell Supply Company, which sold these tires previously. The company expects to move into a new building, now in course of construction at 2212 Farnam street, in a short time.

AKRON, O.—The work of extending facilities for Diamond tire service is still going on, four new service stations having been recently opened—three in the South and one in the Middle West. These new stores are located at 1316-18 Grand avenue, Kansas City; 910 Broadway, Nashville, Tenn.; 229 N. Tryon street, Charlotte, N. C.; 427 S. Twentieth street, Birmingham, Ala.

COLUMBUS, O.—Advance sheets of the annual report of James R. Marker, State Highway Commissioner of Ohio, shows that during the year ending November 15 there were constructed under state supervision 60.88 miles of highway. Of that amount 32.6 miles was water-bound macadam, 8.7 miles bituminous macadam, a small portion concrete and 19.2 miles brick.

MILWAUKEE, WIS.—George W. Browne, 458-462 Milwaukee street, state agent for the Overland and Marmon, last week entertained 52 of his Wisconsin sub-agents at the new Browne service building in Milwaukee. A banquet was given by Mr. Browne in the evening and T. C. Whitcomb, assistant sales manager of the Willys-Overland Company, Toledo, made the principal address.

DAYTON, O.—The Stoddard-Dayton department of the United States Motor Company has decided to centralize its local selling force at the plant and announcement is made of the appointment of Charles Hoffritz as agent. The local agency formerly was in the hands of the Dayton Automobile Company, on West Fourth street. This company will continue in the business and will sell the Winton Six and other lines.

INDIANAPOLIS, IND.—All Indiana agents for the Overland, numbering nearly 100, were entertained by the Fisher-Gibson Company at that concern's salesrooms on December 12. A dinner was served in the salesrooms. Among those present was John N. Willys, president of the Willys-Overland Company, and other representatives of the Overland factory. A theater party was given for the visitors during the afternoon.

INDIANAPOLIS, IND.—Visitors representing hundreds of thousands of dollars' worth of business were entertained last week at the Premier factory. All were Premier representatives at various points in the country and some of them rank among the most prominent automobile dealers in the United States. F. M. McFarland, the leading motor car dealer of Honolulu, was among the number. Premier cars will be shipped to Honolulu for distribution in the Hawaiian Islands on a bigger scale than ever.

DES MOINES, IA.—The Brown Corley Ellis Company has taken the Des Moines agency for the R. C. H. car.

SPRINGFIELD, MASS.—C. J. Clark and J. M. Greenlees have opened an agency here for the sale of K-R-I-T cars.

LOUISVILLE, KY.—The Kentucky Automobile Company has taken the agency for the Standard electric. This concern is also the agent for the Cadillac car.

CINCINNATI, O.—The W. C. Jungclas Company has taken the agency for the Thomas Flyer in this city. This concern also handles the Overland.

LOS ANGELES, CAL.—The Hayes Auto Sales Company has moved into its new quarters at 1225 S. Olive street. It will handle the Hayes and Krit cars.

MILWAUKEE, WIS.—The Pauly, Bruce & Goldacker Company, state agent for the Stoddard-Dayton, has taken the agency for the Universal and Chase truck lines.

SPRINGFIELD, MASS.—The Western Massachusetts Cadillac Company has been formed in Springfield by E. R. Clark, and the new company will handle the Cadillac product.

DES MOINES, IA.—J. E. Ullman closed a contract this week for the local agency for the Ohio car. He will have offices and show rooms with the Independent Auto Company.

LOS ANGELES, CAL.—The Pathfinder Motor Car Company is now located here and will handle the New Parry and Speedwell cars. It has leased the building at Pico and Hill streets.

WASHINGTON, D. C.—G. C. Bensinger & Bro., 301 Sixth street, N. W., agents for the Ohio, have secured the Grabowsky truck agency and will inaugurate a service department in connection with it.

NEW CASTLE, PA.—Patterson & Emery, prominent automobile dealers of this city, have contracted with the Franklin Automobile Company, of Syracuse, N. Y., to handle Franklin cars for the season of 1912.

FOND DU LAC, WIS.—W. C. Reinig was elected president of the Crescent Motor Company at the annual meeting. H. S. Wilson is secretary and treasurer. The company is building a large addition to its plant.

TOLEDO, O.—It is unofficially announced that T. W. Warner, president and general manager of the Warner Manufacturing Company of Toledo, will build a new plant at Muncie, Ind., to be operated by a company called the Warner Auto Parts Company.

BOSTON, MASS.—The Matheson Automobile Company will shortly open a completely equipped service bureau, a branch of the parent company of Wilkes-Barre. A large building on Commonwealth avenue especially constructed for automobile service has been chartered.

MILWAUKEE, WIS.—The National Brake & Electric Company, of Milwaukee, a unit of the Westinghouse interests, has increased its capital stock from $1,000,000 to $2,000,000. The company manufactures a number of compressed air and electrical devices and equipment for garages.

Automobile Incorporations

AUTOMOBILES AND PARTS

P. W. Mulford, of Cincinnati, O., winner of first prize in Winton upkeep contest

OF INTEREST to the INDUSTRY

New factory of the K-W Ignition Company in Cleveland, Ohio.

CLEVELAND, O.—The K-W Ignition Co. has moved into its new factory at 2833 Chester avenue. The building is of steel and concrete construction and is fireproof throughout. It is 165 feet long and 75 feet wide and has over 2 acres of floor space.

RUTLAND, VT.—The Frenier Automobile Co. is constructing a large addition to its plant in this city.

BOSTON, MASS.—The G. E. & H. J. Habich Co. has been incorporated to manufacture automobiles.

HICKORY, N. C.—The International Motor Co., of this city, will erect a plant here to manufacture automobiles.

DETROIT, MICH.—The Cadillac Motor Car Co. will erect a $12,000 brick warehouse and a $10,000 boiler house on Burroughs street.

NASHVILLE, TENN.—The Hermitage Motor Co. will erect a plant here for the manufacture of automobiles and motor trucks.

ATLANTA, GA.—The Piedmont Auto Manufacturing Co. has been organized here to manufacture automobiles. The company will erect a plant.

GRAND RAPIDS, MICH.—The Michigan Suto Joint Company, of this city, expects to begin manufacturing soon at the rate of 300 to 500 joints a week.

AKRON, O.—The Goodyear Rubber Co. has declared an annual dividend of 12 per cent. on its common stock, payable January 1 to holders of record December 22.

FORT WAYNE, IND.—The Ideal Auto Co., of this city, has increased its capital stock from $50,000 to $100,000. G. H. Hall is president and F. H. Safford is secretary of the company.

FOND DU LAC, WIS.—The Dallman & Cooper Supply Company has made a large installation of welding and cutting apparatus manufactured by the Oxy-Acetylene Welding Machine Company of Kansas City.

NEW ALBANY, IND.—American Automobile Mfg. Co. is installing additional machinery for the manufacture of motor trucks. Geo. A. Buckley is superintendent of the plant. Trucks will be built in three sizes.

ANTIGO, WIS.—The International Hoist Company, which recently absorbed the Pioneer Iron Works, manufacturing gasoline engines and motors, has decided to erect a new plant in 1912 and is now selling $20,000 worth of treasury stock.

FREMONT, O.—The Lauth-Juergens Motor Car Co. has just completed plans for a new building 250 by 60 feet, which is to be used for the assembling and body-building departments of the factory. Another large building will be erected in the spring.

DETROIT, MICH.—With the end of the 1912 season still six months away the sales of the Packard Motor Car Co. already equal the entire output for the season of 1911. The increase in sales is largely due to the new six-cylinder model. Sales of Packard trucks for the year 1911 will about double the 1910 output.

DETROIT, MICH.—The market for the first week in December bears out indications that the present inactivity in the machine tool trade will continue until after the first of the year. Merchants are hopeful of renewed activity in January. The automobile and accessory plants are busy.

MERRILL, WIS.—Edward Heldt has been granted letters patent on a rotary expansive steam engine which by a suitable governing device may be made to take live steam through any portion of its revolutions, running the remainder of the revolution on expansion, and capable of having the direction of rotations easily and quickly reversed. The engine has no dead center and hence is capable of starting at any point in its revolution. As a result it has a direct, constant, and uniform torque on the driving shaft. Mr. Heldt is making plans for the manufacture of the engine at Merrill.

FINDLAY, O.—Findlay may have a new factory for the manufacture of automobile trucks if plans now before business men are carried through. The truck itself is the invention of Messrs. Ludwig Leitner and M. Weiting, two Findlay men who have been connected with the manufacture of automobiles for the past ten years. The truck invented by the two men is different in all respects from the average truck now on the market. Its chief feature is a chainless drive. It is also characterized by the location of the radiator, which is in the rear of the engine instead of in the extreme front.

INDIANAPOLIS, IND.—A new Indianapolis concern is the Bright Carbureter Co., which is to establish a factory at once. The company has been incorporated with an authorized capitalization of $25,000, which may be increased to $200,000 with the consent of two-thirds of the stockholders. Those interested in the company are: Ulric Z. Wiley, former judge of the Indiana Supreme Court; Samuel H. Brundage, of the advertising staff of *The Indianapolis News;* Clifford Arrick, broker; Henry S. Rominger, president of the Indianapolis Fancy Grocery Co., and Dr. Clark E. Day.

TORONTO, ONT.—The Schacht Motor Car Co. of Canada, Ltd., has been organized by prominent Toronto capitalists to manufacture Schacht cars for the Canadian trade. By an agreement with the United States company the Canadian company has all rights to any patents and improvements which may be obtained by the parent concern. The company has offered to the public 7 per cent. cumulative shares of preferred stock at $10 a share, each share carrying a 20 per cent. common stock bonus. In all this amounts to $15,000. Common stock to the value of $200,000 has also been offered. Orders have been received to keep the factory in full operation for several months to come.

PATENTS GONE TO ISSUE

ENGINE—Internal-combustion motor of the rotary overhead sleeve type.

4. This patent refers to an engine which comprises a cylinder and piston, as well as a casing with a port leading into the cylinder and a second port connected by a passage with the first-mentioned port. One of the ports is located in advance of the other. In the casing a valve plug is mounted revolubly and having a port located in a plane of rotation coinciding with the position of the first-named port. The purpose of this arrangement is to admit periodically an explosive mixture. The valve plug also has an exhaust port in free communication with the atmosphere and at all times totally disconnected from the first-mentioned port.

No. 1,011,601—to Albert Harris Forsythe, Joplin, Mo. Granted, December 12, 1911; filed March 29, 1910.

VALVE MECHANISM—Method of operating valves by reciprocating member between cam and valve stem.

1. The mechanism (Fig. 1) comprises a valve and stem, the valve being normally closed by a spring, but connected to a revoluble cam by a reciprocating arm. An adjustable nut is stationed immediately between valve stem and reciprocating mechanism and the nut contains a normally spring-protected member.

No. 1,011,695—to Alexander Winton, Cleveland, Ohio. Granted, December 12, 1911; filed April 29, 1911.

SAFETY APPLIANCE—Device for holding wheels in position on axle.

3. The appliance protected by this pattent (Fig. 2) comprises a collar formed on an axle, wheels being mounted on either side of the collar on the axle, and each wheel having a hub. Plates are mounted on the axle and surround the collar, the collar holding the plates against longitudinal movement on the axle. Bearings on the plates support the adjacent ends of the wheel hubs, one bearing being on the inner end of the axle and one being removable, mounted upon the outer end of the axle.

No. 1,011,852—to Ernest Legrand Robertson, Greenville, S. C. Granted, December 12, 1911; filed January 9, 1911.

EXPLOSION ENGINE—Rotary sleeve valve motor of the two-stroke cycle type.

2. The engine (Fig. 3) protected by this patent combines the features of a motor cylinder connected with the crankcase as a compression chamber, and having an exhaust passage. The whole flow of incoming and outgoing gas is controlled by the position of one rotary valve.

No. 1,011,748—to Howard E. Coffin, assignor to Chalmers Motor Co., Detroit. Granted, December 12, 1911; filed April 9, 1909.

FRICTION CLUTCH—Transmission member of the cone type.

4. This clutch (Fig. 4) comprises a driving shaft and a driven one in alignment with it, as well as a casing with oppositely inclined faces carried by one of the shafts. The faces are in constant relation to one another, and a number of radially movable friction members are in engagement within the casing. A sleeve having wedge faces is keyed to the driven shaft, and means are provided for holding the friction members in engagement with the friction faces of the casing, as well as means for yieldingly holding the friction members in engagement with the friction faces. The sleeve may be actuated lengthwise of its shaft out of centrifugally actuating contact with movable friction members, whereby they are released from positive engagement with the friction surfaces of the casing.

No. 1,011,834—to Harry W. Nichoalds, Detroit, Mich. Granted, December, 1911; filed October 10, 1910.

LIQUID ATOMIZER—A specially shaped nozzle which tears up the particles of a fluid forced through it.

1. This patent refers to a nozzle consisting of a body with an exit communicating with the passage of a disk overlying the body. Over the disk is fitted a tip covering a portion of the passage mentioned and having a conical recess with a discharge port leading from same. The covered portion of the passage enters the recess tangentially.

No. 1,008,119—To Knut M. Dahl, San Francisco, Cal., assignor to Union Iron Works Co., San Francisco, Cal. Granted November 7, 1911; filed June 12, 1911.

PNEUMATIC JACK—Device for raising loads by air under pressure.

1. In this jack a cylinder containing a piston is combined with means for conducting a fluid to or from the interior of the cylinder beneath the piston, so as to cause the latter to reciprocate. The means named comprise a hinged rigid tubular handle connected to the cylinder and valved means on the handle for controlling the flow of the fluid under pressure.

No. 1,010,927—to Clarence H. Letcher, San Jose, Cal. Granted December 5, 1911; filed June 26, 1911.

Newest Ideas Among the Accessories

Vanometer Gasoline Gauge

THE Vanometer shown in Fig. 1 is a gasoline gauge of extreme simplicity of construction, as it has hardly any mechanical parts at all. It operates on an application of the principle of communicating vessels, the installation of the instrument and its connection with the gasoline tank being clearly depicted in Fig. 3.

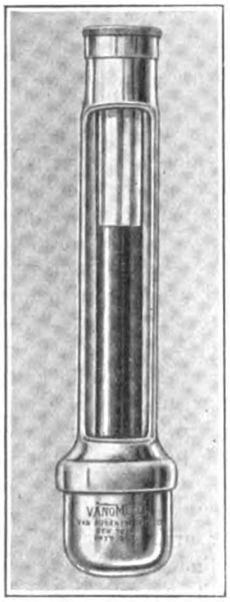

Fig. 1—Vanometer

The Vanometer consists of a U glass tube, 1-2 inch in diameter and filled with a red liquid of a certain specific gravity and chemical composition. The top of the one leg of the U tube, which is contained in a nickel casing, has an opening, so that the air above the liquid is in communication with the outer air. The other leg of the U tube is just high enough to hold the liquid when it is on the same level in both legs of the tube. This lower leg is connected to the empty gasoline tank by a gas tube after the Vanometer has been installed on the dashboard in any desirable position. In installing the gauge the level at which it is placed does not matter.

The Vanometer being in place on the dash, a 1-4-inch hole is made in the top of the gasoline tank and a coiled tube is put through the opening so as to have its lower end almost in touch with the bottom of the tank, and the pipe is connected to the branch of the Vanometer. After this the gasoline is poured in the tank, until the red fluid in the nickel-encased glass tube rises to the top of the latter, which indicates that the tank is full. This holds good for any shape and size of gasoline tank, if the Vanometer has been installed while the tank was empty. The length of the connecting member of the U tube is such that the highest gasoline level corresponds to the highest possible level in the instrument. As the gasoline is being consumed by the engine cylinders the air in the gas tube travels toward the tank, the gasoline falls to the bottom of the tank and the red liquid falls to zero, while the half-height of level in the tube corresponds to a half-filled gasoline tank, and so forth at various levels.

The Vanometer operates equally with gravity or pressure feed systems, as only the level in the tank influences that in the indicator tube. It is made by the Van Auken Indicator Co., 123 Liberty street, New York City, in sizes for automobile tanks as well as for garage storage tanks.

Single Button Switch

The button switch shown in Fig. 2 is unique in that it has but a single button for turning the lights on and off. In operation the button is first pressed in to turn on the lights, after which it immediately returns to its normal position. A second push on the button, after which it returns to the normal location, and the lights are out. The maker, Joseph F. O'Brien Co., 61 Park Place, New York, claims that the single button switch was perfect over a test of 15,000 pushes, which is more than practice requires.

The switch is easily installed, requiring only one hole to be bored in its round body.

Traver Patent Blowout Patch

This patch fits the inside of the shoe and keeps in position as long as the shoe remains in service, without being cemented or strapped, laced or bolted, as it is equipped with a sort of metal bead by means of which it locks on the rim.

The Traver patch is made of highly compressed Sea Island cotton and covered with high-grade rubber and hand-made throughout. It is moulded or cured, so that the fabric is neither crowded nor overvulcanized. Its friction surface gives it additional holding strength and it is made flexible on the sides and ends so as not to chafe the inner tube. The patch is the product of the Traver Blowout Patch Co., 1779 Broadway, New York City.

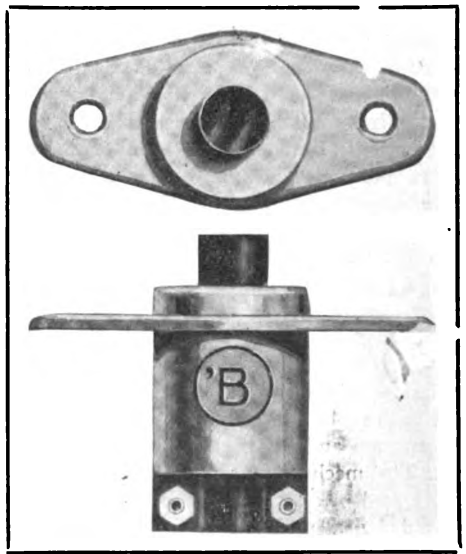

Fig. 2—Single button switch

A. A. Gas Lighter

The Auto Appliance Mfg. Co., of 18 Buchtel avenue, Akron, O., has begun to manufacture and sell a device producing a high-tension jump-spark across a gap located above the acetylene headlight burner. The system combines this igniter with the acetylene piping system, in that the flow of gas is controlled by the handle of a needle valve on the dash. One terminal of the battery is connected to the coil and the other to the piping system which thus closes the circuit as soon as the gas is turned on.

VOL. XXV NEW YORK—THURSDAY, DECEMBER 28, 1911—CHICAGO No. 26

THE AUTOMOBILE

Garden of Allah as Touring Field

TOURISTS IN ALGERIA TRAVELING ALONG THE BED OF A CREEK AT BISKRA

FOREIGN touring *en motor* is shrouded with more or less glamour and despite the fact that each year finds a large increase in the number of American tourists who seek foreign fields for pleasure and recreation, a material section of whom are automobilists, there is still sufficient novelty about a foreign trip to make it very attractive.

The show places of Europe are become beaten pathways for American automobile parties and as Asia and South America are still somewhat too chaotic from a road viewpoint to make good touring fields, the attention of prospective visitors is naturally directed toward Northern Africa after the splendors of Europe have been exhausted.

At the present moment the war being carried on by Italian troops in Tripoli has centered the eyes of the world on the Mediterranean coast of Africa. Egypt has long been familiar with the automobile. Tripoli has been too unsettled politically to attract tourists with their cars to any great extent and the same might be said for Morocco, on the Atlantic coast.

But Algeria, the French sphere of influence in northern Africa, presents a more attractive outlook for the automobilist who desires to tread more or less unbeaten paths.

The city of Algiers, capital of the department, is situated on the sea coast in about the same latitude as Washington, D. C., St. Louis, Mo., and San Francisco, Cal. The country extends southward in three great upward steps until human boundary lines are lost in the shifting, mysterious sands of the Sahara.

The Atlas mountains run parallel with the coast from Tunis to the eastern boundary of Morocco. These mountains, which are not particularly lofty nor impressive from the modern viewpoint, have been famous since mythological times because they were likened to the giant Atlas, who was said to support the world on his shoulders.

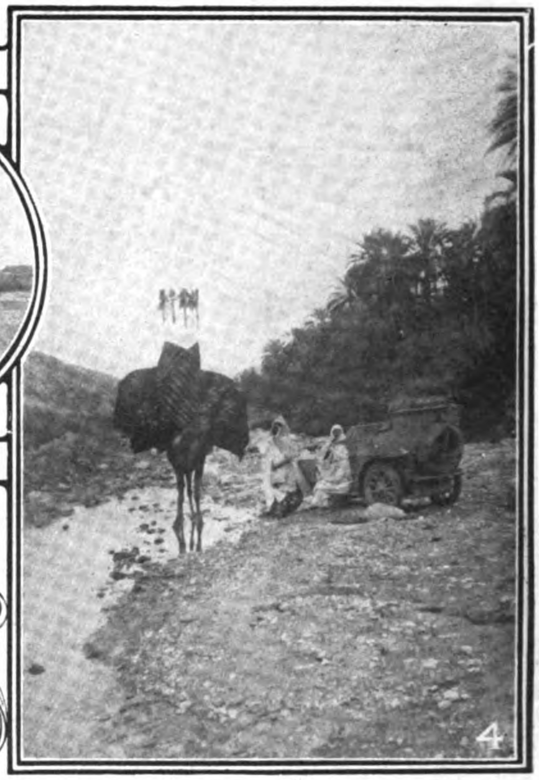
South from the mountains lie a series of plains call sebkhas, which are covered with vegetation similar in character to the plains of Idaho. Numerous salt lakes are sprinkled here and there over the sebkhas. This section is bounded on the south by another range of mountains and behind the mountains is the Sahara.

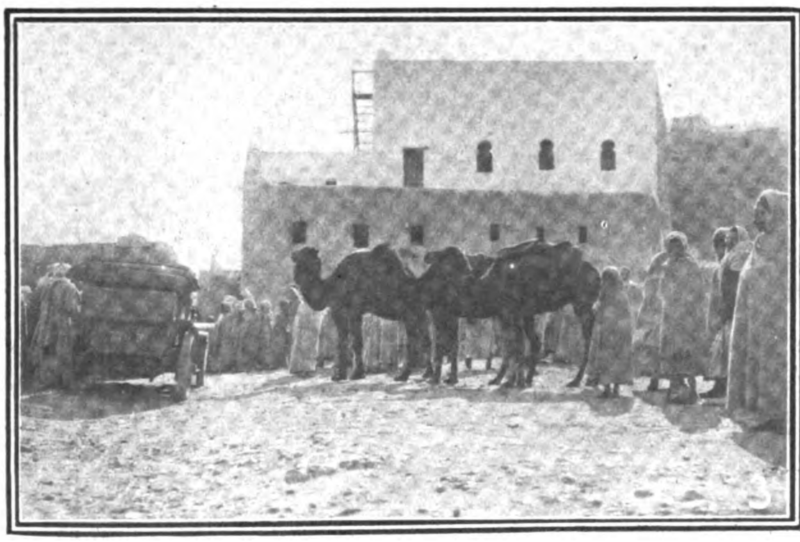
The northern valleys are fertile and under the name of the Tell, once constituted a factor in supplying grain to various European countries, especially Itally. Algeria has a mean temperature of 63 deg., which makes it excessively hot in summer, but delightful for American tourists from November to April.

The history of Algeria explains why there are probably 1,000 miles of excellent automobile highway in the country. The Moors, Arabs, Turks and negroes never built a road except under military compulsion, and as military exigencies along the lines of road building were never pressing during the control of the country by either of the elements mentioned, the present road system may be attributed almost *in toto* to the French.

At the beginning of the Nineteenth century Algeria was a Turkish dependency. It was governed by a combination composed of a native dey and a Turkish pasha. Being somewhat isolated from the fountainhead of the Ottoman government, the dey of Algiers was able to strain the bonds sufficiently to allow a system of piracy to become the chief industry of his subjects. All nations either paid tribute to the corsairs or suffered robbery at sea. Time after time punitive expeditions were directed against the practices of the deys but nothing decisive was accomplished until Commodore Decatur, of the United States Navy, destroyed the sea power of Algeria in battle and crushed the institution of piracy, causing the release of 1,200 European and American slaves who had been taken in the various incursions of the piratical deys.

In 1830 the Turkish power in Algeria was broken and the Turks expelled by the invading French. For 40 years after the initial occupation, the French were constantly embroiled, occasionally defeated by the Arab chieftains and always more or less tangled up with war, graft and mismanagement. But since 1870 the situation in Algeria has become more stable and today, while the country is much less traveled than Egypt, it is practically as safe as France itself from the standpoint of the automobile tourist and still sufficiently unknown to the world generally to prove attractive.





2—Departure of a caravan of camels escorted by an automobile

3—All the natives come out to witness the arrival of the tourists

4—Ancient and modern means of desert travel exemplified

The history of the roadmaking in Algeria is closely associated with the French military occupation. The first expeditions were in the nature of landing parties backed by the fleet and the soldiers stuck closely to the garrisoned cities. When it became necessary to repel attack the sorties were made by flying columns and the distances covered were comparatively unimportant.

The history of nearly all of the French expeditions proved to be similar until a different plan was devised. The French generals would gain victory after victory against the elusive and well-mounted irregular cavalry and once in about 10 years an army division would be wiped out by the Algerians. It has been estimated that the French occupation cost the lives of 150,000 men and $800,000,000 up to 1870.

But a few years before that date an improved plan of occupation had been devised and instead of moving against the shadowy Arabs with flying columns, the Europeans gradually forced them back by main strength, establishing civil governments in the places within their lines, building military roads in their rear and step by step forcing the natives into the hills and beyond. This plan proved effective and in a surprisingly short space of time the leaders of the insurrection were pushed out into the Sahara and there was peace in Algeria.

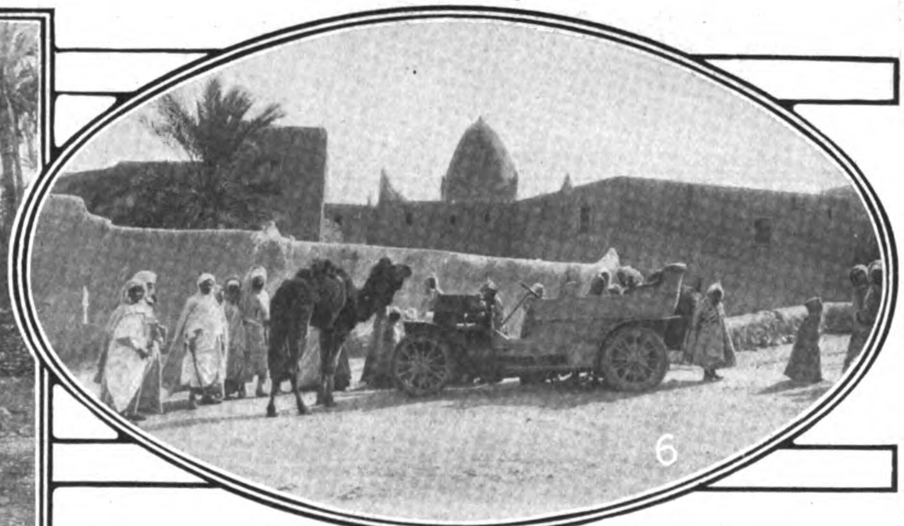
The uninhabitable character of the desert, save here and there where springs and wells cause an oasis to bloom amid the somber sand, marks the limits of civilization and while practically all the country included in the classification sebkhas, can be made exceedingly productive, the really productive section at present is represented by the same valleys in the Tell that have been granaries since the time man first required grain.

An automobile tour through the Tell, while interesting and in a certain sense unusual, is not sufficiently so to make the journey worth while. But if the tourist wishes to enjoy something really unique he may tour from the city of Algiers to Biskra, an oasis in the sebkhas, less than 200 miles in a direct line, but by the military roads the distance is nearer 450 miles.

Leaving Algiers, the road east, following the sea coast, is magnificent for 50 miles. It was once the main military artery in the French scheme of occupation and traverses a country that resembles the soil and general appearance of the north Georgia mountains and in January is not unlike that portion of the United States in September or October.

There are two good ways to reach Setif, which is a divisional point on the route from Algiers to Biskra. The first of these is to take the coast road through Tizi Ouzon to Bougie and then go south through Kerratta, reaching Setif from the north.

The other way is more spectacular and interesting. The coast road is very similar to the average well-kept French highway, although it is set in a picture of vastly more interest than is presented by the usual French country side. But the alternate road that may be used in reaching Setif is interesting in every stage. The first stretch is identical with the coast road, but branches off to the south about 30 miles from Algiers. The coast road continues east to Tizi Ouzon, about 60 miles, the last 15 of which are rather winding and encompassing a number of sharp grades.



5—The natives were astonished at the appearance of the tourists

6—There were a few formalities necessary outside of Biskra's walls

7—The natives and their families insisted upon being given a ride

The country traversed is devoted to grape culture to a large extent and is delightfully attractive to the eye and senses.

Tizi Ouzon makes a good luncheon stop for the first day and the facilities to be found there are ample. The afternoon run is rather long, but the road surface is so perfect that little difficulty will be experienced in getting to Bougie in ample time for dinner. The afternoon run from Tizi Ouzon is largely up grade, with a few steep hills to climb and from the summits of these successive ranges, glimpses of the blue Mediterranean can be caught. For one long stretch before reaching Bougie the road ascends a 3 per cent. grade so evenly that it is difficult to tell while running whether the car is going up or coming down.

Bougie is an ancient seaport and has a most interesting native

General view of the oasis of Biskra from the opposite side of the river

quarter which will repay investigation by the tourist. Gasoline costs 33 cents a gallon at Algiers and gradually increases the further one gets away from the railroads. The roads are rather narrow, ranging from 10 to 14 feet. Like the best military roads, they were constructed with small regard for labor. There are some spots where they wind tortuously through canons, but as a general principle the engineers constructed them with the idea of making the passage of artillery as easy as possible. This accounts for the long, gentle and almost inappreciable grades such as the one entering Bougie.

All along the coast from Algiers to Bougie the road leads through vineyards which have taken the place of grain fields to a considerable extent. The grapes of Algeria have a worldwide reputation and are in demand wherever they may be shipped.

Let no tourist undertake this journey without a camera and plenty of plates and films, for each hour of the way will afford opportunity to take pictures of extraordinary interest and beauty.

There will be no trouble experienced in missing roads in northern Algeria. In the first place the roads themselves are infrequent and the main highways cannot be mistaken. The occasional cross-roads are usually marked and as a consequence there is little probability of losing the road. The hotels are surprisingly good along the coast.

The next stage of the route is to the ancient town of Setif. This place lies a little east of south from Bougie and is located about the center of the fertile interior plateau in the northern section of the country.

The roads are similar to those encountered in the run from Algiers, but as they ascend toward the foothills of the Atlas mountains they are narrow and winding.

The run from Setif to Biskra may be made in one day, but it is advisable to cut the itinerary in two so as to take in the city of Timgad, which was used for centuries as the headquarters of the desert hordes which made periodic descents upon the constituted authorities, native, Turkish and French.

The tourists must retrace their course along the road to Lambese and Batna before regaining the ascending trail across the Atlas range. In this particular section the mountains are called the Aures. East of the pass El Kantara through which the travelers go, the craggy steeps tower into the sky and set up a barrier that is entirely impassable to automobiles, but the road to be followed is good clear to the summit. It winds southwestward around the foothills and then enters the pass of El Kantara, a canon, the walls of which almost shut out the daylight they are so high and stand so close together. This was the pass once captured by the Romans that was held for 300 years by one small tribe of Kabyles against the assaults of all other tribes and the military operations of the Turks and Europeans.

On the northern side of the pass the climate is laden with the adequate moisture from the breath of the sea. The hills are covered with verdure; the vines hang heavy with luscious fruit and the fields bear luxuriantly. But as soon as the summit is passed and the travelers emerge on the south side of the pass the whole scene is metamorphosed. The same transition has taken place that is so noticeable in crossing the Cascade mountains in Washington and Oregon. At Portland or Seattle the climate is moist and the natural verdure is almost sub-tropical, but east of the Cascades it is as dry as the Sahara, the reason for this marked difference in climate between sections that are adjacent is the same in Africa as it is in the United States. The rocky wall of the Atlas mountains serves as a barrier for the sea breezes. The cold peaks precipitate the moisture when the winds from the Mediterranean touch them, but the rain falls on the northern slope and whatever portion of the north wind succeeds in getting over the range has been stripped of its life-giving moisture.

Thus the country south of the pass looks like eastern Oregon. Sagebrush, or something closely resembling that plant; greasewood and heather are about the limits of vegetation. The air is dry and the climate has all the characteristics of the desert.

But there is one material difference between this section of Algeria and that of say, southern Arizona. The geology of the country is such that springs are frequent, even in the desert. The bed rock lies close to the surface and where minor faults occur the water flows out of the ground.

The marvel of nature is seen where this happens. On all sides the yellow barren sand gives no promise of life, but where these little springs flow forth the desert blossoms into an oasis. Date palms, gracefully nodding in the soft breeze, are typical of the oasis and wherever the water flows, the sand produces abundant vegetation. Cattle, camels, goats, sheep and horses have thriven for centuries on the fodder provided by the desert springs and clear to the edge of the great, arid Sahara, the oases support a large permanent population.

Oases range in size from an acre of isolated palms, sufficient in size to support a single family, to garden spots 12 or 15 miles in diameter, entirely surrounded by dry sand and having no apparent inlet or outlet for the spring-fed ponds and lakes with which its surface is dotted.

The city of Biskra, with its considerable population and its array of shining white buildings, is situated in the midst of such an oasis, which is reported to hold 150,000 palm trees.

Just after leaving the mouth of the pass a new bridge has been constructed to carry the road across a deep canon. This bridge recently has been finished and is a vast improvement over the former method of covering this section of the road.

The accompanying pictures indicate something of living conditions as they are found at Biskra. The oasis is extensive and besides the Kabyles, Turks, negroes and Bedouins there are many Europeans. Some fine residences have been erected by French noblemen at Biskra, which are used for homes from 7 to 9 months in the year.

The military road system of Algeria comprehends two complete parallel lines of road. The first extends generally along the coast from Oran to Tunis. The second skirts the hills from 30 to 40 miles back from the coast. Between these two lines there are cross-roads at irregular intervals and a third line of parallel road has been partially finished.

Extenting south from the main sea-ports are roads that penetrate the second mountain range and in the case of the road by which Biskra is reached, the road continues out into the desert as far as Tougourt. This is the same road that starts south from Bougie and the large city of Constantine. The longest southerly road leading directly from Algiers passes through Chiffa and Medea; climbs the mountains through a gorgeous pass and strikes south through Boghari and El

Krachem to Lagouat and finds its terminus deep in the Sahara at Ghardaia. Another road from Algiers runs through Arba and Aumale to Bou-Saada, a small place in the northern foothills of the Oulad Nail.

A tour of Algeria may well occupy a whole winter but the more interesting points may be covered in from 4 to 6 weeks. There are several ways of reaching Algiers from the United States, but all of them require transshipment of the car. Steamer lines from the French Atlantic and Mediterranean ports are probably more direct than others. The cost of shipment is in the neighborhood of $125 from New York. Gasoline at its cheapest is twice as dear as it is in the United States and good oil is scarce and costly. If the party contemplates going away from the regular automobile routes, provision had better be made for supplies of fuel and oil, as it would be very annoying, and perhaps dangerous to run out of them in the desert.

A party of tourists who have been making the rounds of Algeria, requiring a period of six months to do so, give some interesting details regarding automobile travel there. The cost for shipping a motor-car from Southampton, England, to Algiers is $70, besides $5 for unloading at Algiers. The Algiers shipping authorities extend satisfactory courtesies; although the reliability of the Arab assistants is not by any means certain, these not exercising the least concern over missing tools or seawater in the radiator. As a rule, the hotel accommodations are excellent. Signs are displayed notifying automobilists that garages are maintained, and also that this or that particular hotel is recommended by The Automobile Club of France. It is not difficult to obtain petrol in any village. The roads of southern Algeria are very carefully made, a great roller, drawn by many teams of mules or horses being used. The quality of the work compares favorably with that which is done by a steam-roller.

A Budget of News From Australia

SYDNEY, N. S. W., Nov. 26—Since February of this year trade has grown to a very considerable extent, so much so that those who profess to be any authority predict that a crisis is near at hand and many agents, especially those recently started, may go out of business. As was said nearly a year ago, every leading European car had an agent here and others starting had to look to America for their lines, and the result has been that almost every car advertised in The Automobile is now represented on this market as well as several other makes, and our population is only 4,000,000 and cars costing much more here than abroad, it is difficult for agents to live up to their contract numbers, and in the end it means someone is going to lose a lot of money, and also there is going to be a large number of cars thrown on the market, and having this end in view, some of the older agents are intending to cut the prices and bring this crisis about early and avoid as much as possible the glutting of the market.

Second-hand cars are a bad proposition in this country and an illustration was given when the General Motor Co., Ltd., went into liquidation on account of serious customs frauds perpetrated by the managing director, who is now undergoing a term of imprisonment for the same. At the liquidation sale a large number of second-hand cars were offered, but although the sale was well advertised and some of the cars were well known, and also of well-known makes, the prices realized were terribly low, and brought only 60 per cent. of expert's valuation, while on the other hand new cars brought within 3 per cent. of the list price. These cars were the Renault and the British Wolseley.

Although the high-priced European car has a good steady market, American cars also have a good market and numbers of Hupmobiles, Fords, Overlands, Chalmers and Cadillacs are to be seen running along the streets, whilst other makes which do not have such pushing agents are also to be seen.

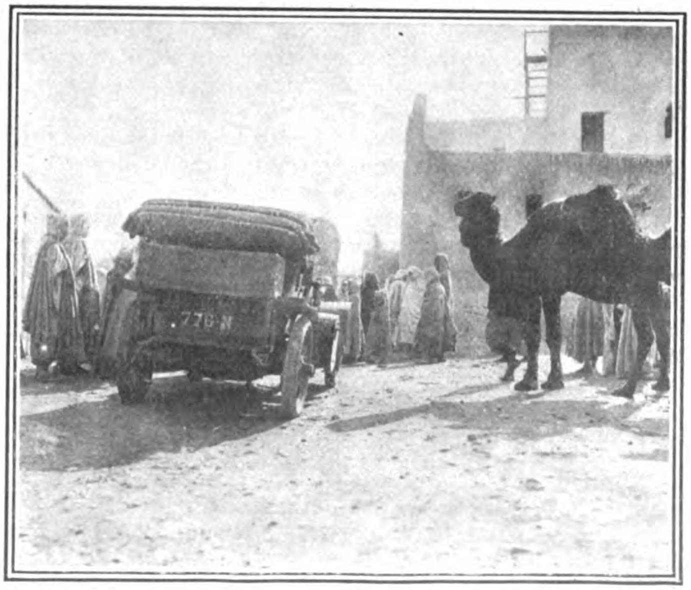
In speaking of pushing agents it might be mentioned that agents of the Hupmobile, Overland and the Hudson were doing a good trade in high-priced British and French cars previous to their taking up any American agency, but since taking American cars they are advertising and pushing the American cars for all they are worth and never mention their European cars.

There is a good trade to be secured in this country by the first maker who introduces a good light delivery van to carry loads up to about 1000 pounds, and such vehicle must be reliable and low cost to purchase, not exceeding $650 in America. As fuel is a costly item here, an economical carbureter is necessary. Air cooled engines will not have any demand, but the car which has solid tires, if only on the back wheels, will also assist the selling. The type of body does not matter, in fact no body at all is the best, as most users are sure to have a particular idea of their own as regards body work, and not only that, the duty on body work is heavy, 30 per cent. ad valorem, whilst the chassis is only dutiable at 5 per cent.

To give an idea of what is required in this line, the Greater J. D. Williams Amusement Company, which company is the leading moving picture enterprise in this country, is using a Brush car fitted up to carry a few hundredweight.

There is also another line that could be pushed in this country and that is stationary engines suitable for farm work. Most farmers are using the expensive English oil engines and on account of their heavy weight they render themselves a little unsuitable for shifting about, while a light gasoline engine will be more suitable, and already there are several lines on the market. Apart from those sold by the International Harvester Company, the Ferro engine is doing well, but there is no reason why lines of this description should not take the entire place of the heavy and clumsy engine.

Sundries of American make are slow in making their appearance in spite of the advice given in The Automobile some 6 months ago, and what is really required is a good distributing house to introduce useful lines, and have them properly represented to realize a good return on the investment.



The camels contemplate their successor with placid mien

Industrial News by Mail and Wire

SOUTH BEND, Dec. 26—J. M. Studebaker, Sr., who for 54 years has been vice-president or president of the Studebaker Brothers Manufacturing Company, has resigned to become chairman of the board of directors of the Studebaker corporation, which was organized in the latter part of February, with a capital of $45,000,000.

Frederick S. Fish was elected president of the corporation, Clement Studebaker, Jr., was chosen vice-president and chairman of the executive committee; A. E. Erskine, treasurer; Frederick P. Delafield, of New York, special counsel, and Scott Brown, of this city, general counsel and secretary.

J. N. Gunn, of New York, was appointed general manager of the corporation, co-ordinating the administration of the automobile division, the horse-drawn vehicle division and the harness division of the business. The other officers of the corporation remain as before.

News of Detroit Factories

DETROIT, Mich., Dec. 26.—C. C. Hildebrand, assistant general manager of the Chalmers Motor Company, who has just returned from a tour among the Chalmers dealers that embraced the entire country, is most enthusiastic over the outlook for the coming year and is quite satisfied with present conditions for the season of the year.

"I have never known the prospects for the industry to be any better," he said. "In all parts of the country Chalmers dealers report business far ahead of last year and indications for the spring are certainly very encouraging. A great many of our dealers have already sold from 80 to 100 per cent. of their 1912 allotment, and the demand for additional cars is general. I was especially surprised over the business being done in the South, and when the South gets better roads it is going to be a great field. And down in Cuba the motor car is becoming more popular every day. The island is beginning to literally swarm with them. This has been the biggest December in the history of the Chalmers Co. Our sales for the month to date are more than 250 cars ahead of last December."

Employes of the Chalmers factory had material evidence of the company's prosperity in the form of an extra week's pay, which was handed them Friday noon as a Christmas remembrance. Every factory hand who had been in the company's employ for six months or more and every member of the office force who had been with the concern a year or longer was a beneficiary in this distribution of Yuletide cheer.

The Hudson Motor Car Co. also took a hand in the Christmas giving, providing 17 poor families with substantial dinners today and all the clothing that was needed.

The Studebaker Corporation has come into actual possession of the factory at Port Huron, now known as plant No. 2, where for the past five years rear axles for the E-M-F "30" and Flanders "20" cars have been manufactured, together with eleven lots. The property was originally donated to the Northern Motor Car Co., which was one of the companies that were merged to form the E-M-F, on the condition that it be used for the manufacture of automobiles or automobile parts. When the plant had been occupied five years the Port Huron Chamber of Commerce was to turn over the deeds, provided the firm occupying it had paid out $200,000 in wages. The time limit expired several days ago, and the company having fulfilled the other conditions there was nothing for the Chamber of Commerce to do but turn over the deeds, which it did cheerfully. The plant now employs 500 men and has been one of the main industries of the Tunnel City for some time.

The Argo electric brougham, manufactured in Saginaw, made its first appearance in Detroit Saturday and attracted no little attention. It is a low-hung car with sweeping lines. It has a steering wheel instead of a lever, a direct herringbone gear drive, chainless and noiseless, and the Argo combined speed control and brake. George Waller, sales manager for the Argo, is in the city to arrange for an agency here.

Case Company to Change Form of Name

RACINE, Wis., Dec. 26.—It is reported that the J. I. Case Threshing Machine Co., of Racine, Wis., the largest industry of its kind in the world, and for some time manufacturing motor cars, having purchased the Pierce Motor Co., of Racine, will reorganize immediately after January 1, in order to greatly extend the scope of its activities.

The name is to be changed to the J. I. Case Co., and new lines of machinery and implements will be produced. It is reported that the extension of activities will include the entrance into the motor truck and farm tractor field.

Alco Truck as Aid to Santa Claus

A 3-ton Alco truck, equipped with solid tires, has been engaged this week in one of the most trying endurance tests that ever has been attempted in demonstrating the enormous capacity for work of a commercial vehicle.

The truck was placed in service Monday to aid the Adams Express Company in handling its Christmas business. It ran night and day for 125 hours. The crew of drivers and helpers was changed every few hours.

In one stretch of 24 hours the truck carried 120,000 pounds of goods, making twenty trips.

Franklin to Continue Some Branches

SYRACUSE, N. Y., Dec. 26—Contrary to the announcement made in certain sections that the Franklin company was about to abandon all its extensive system of branch houses, following the changing of the form of agency in New York and elsewhere, the company declares that the intention is to maintain such branch houses as those in Chicago, San Francisco and in other centers of general distribution.

The reason for the abandonment of the branch houses in New York, Boston and several other Eastern cities is that under the present selling plan of the company the necessity for fully equipped branches has ceased to exist and the business can be handled with more celerity from the factory itself.

Hewitt Heads New Truck Company

Edward R. Hewitt has been elected president of the recently incorporated Hewitt Motor Company, and R. C. Gildersleeve, formerly general manager of the truck department of the Metzger Motor Car Company, has been elected secretary and treasurer.

The company was incorporated for $1,000,000 to extend the manufacture of the Hewitt truck. This car has been made by the Metzger company since about two years ago and is used to a considerable extent in New York for handling coal and other bulky freight. The new company has secured the Metzger interests in the truck and is installing a factory in a six-story concrete building at West End avenue and Sixty-fourth street.

According to announcement the company plans to make a specialty of its service department, which will be coincident with the factory. Mr. Hewitt is now engaged in purchasing machinery which will be installed next month. The directors of the company include M. F. Burns, of Burns Bros., coal operators of this city, the largest users of Hewitt trucks in New York; E. C. Converse, William E. Corey, E. R. Hewitt and Ambrose Monel.

Hope for Champion Wagon Company

In the United States District Court of Northern New York an order has been entered recently appointing Theodore D. Gere and Fred C. Hill, of Owego, N. Y., as receivers for the Champion Wagon Company. Mr. Gere is general manager of the company.

The company has been in financial difficulties for some time and suspended manufacturing operations last month. An immediate effort was made to compound the debts of the company and to keep it running until a plan for solvent reorganization could be discovered and adopted. In an official announcement to the creditors and stockholders Mr. Gere states that the general creditors are willing to discount their claims fifty per cent. in case a reorganization can be effected.

A meeting of the bondholders has been called and the hope is expressed that the receivership will be only temporary.

Klaxon Enjoins Rubber Company

The Lovell-McConnell Manufacturing Company of Newark, N. J., recently brought suit in the United States Circuit Court for the Southern District of New York for alleged infringement of the basic Klaxon patents, 923,048, 923,049 and 923,122, by Henry Phillips.

Mr. Phillips conducts his business under the name of the H. Phillips Rubber Works at 1931 Broadway, New York City. Mr. Phillips, according to the complaint, infringed those patents by cutting prices and otherwise violating the terms of the license set forth on the tags, sealed to every Klaxon and Klaxonet before it is put upon the market. The case came before Judge Ward for hearing on motion, and a preliminary injunction was granted.

Duryea Sells Out; To Form New Company

SAGINAW, MICH., Dec. 26—C. E. Duryea, who recently resigned from the presidency of the Duryea Automobile Company, has announced that he and others will form a new company in the near future to manufacture pleasure cars exclusively. Mr. Duryea is seeking a suitable site for the manufacturing plant.

The settlement of the difficulty that had arisen between Mr. Duryea and the old company was brought about by the sale of his stock to C. C. Brooks. The concern under the direction of F. G. Palmerton will continue to manufacture commercial trucks.

Bennett Promoted in Overland

TOLEDO, OHIO, Dec. 27—George W. Bennett has been appointed vice-president of the Willys-Overland Company, the promotion from the position of sales manager to a berth next to president John N. Willys being made Dec. 20. Mr. Bennett is a veteran in the motor industry and for years was sales manager for the Rambler. Then he joined the Knox forces and after a brief stay with that concern he assumed the managership of the New York White branch, from which position he went to the Overland company.

Penn Unit Machinery Sold to Junk Men

ALLENTOWN, PA., Dec. 26—The plant of the Penn Unit Automobile Company has been sold piecemeal, realizing $45,000. It is said that the property cost upward of $200,000. Most of the machinery was bought in by junk dealers and the real estate went to T. E. Ritter.

Touring Club Plans Southern Tours

TO MEET the increasing demand for the latest and most accurate road data in the Southern States, a path-finding trip under the direction of the Touring Club of America will start within a fortnight from Augusta, Ga., going to Nashville by way of Atlanta and Chattanooga. This trip, which will cover upward of 600 miles, will be made under the direction of the Southern Vice-President, D. D. Armstrong, of Atlanta.

An interesting feature of this scouting trip will be the charting of one of the most delightful Southern routes, which will be taken by a large party of motorists and good roads enthusiasts early in February to attend the automobile show to be held in Atlanta, Ga., in the Auditorium-Armory from February 10 to 17 under the auspices of the Atlanta Automobile and Accessory Association. Parties are now being formed in many of the cities along the route and the forthcoming tour, as a preliminary to the South's big automobile exposition, will be the greatest demonstration that has yet been given of the increasing interest throughout the South in automobile progress and the need of improved highways.

This path-finding run, with which the Touring Club of America will inaugurate the campaign of 1912, is but one of a series of similar road scouting trips through the South and other parts of the country which will be made within the next few months to secure road data for the Automobile Blue Book, the official guide of the Touring Club of America. The Augusta to Nashville tour will greatly enlarge the road and touring material acquired by the Touring Club.

The road from Nashville to Chattanooga with the exception of one short stretch, which will be improved before the Atlanta Automobile Show tour starts, is in very good condition. The Chambers of Commerce, Boards of Trade and civic organizations along the route are showing a keen interest in this good roads demonstration and ample assistance toward improving many sections of the highway has been promised.

Mr. Armstrong will have the co-operation of J. M. Waite, one of the leading good roads boosters of Nashville, and Houston Harper, of Chattanooga, manager of the Touring Club's branch in that city, who will have general charge of the preliminary work in their respective cities and will make arrangements to receive and properly entertain the motorists traveling to the Atlanta show early in February.

It is not improbable, providing weather conditions will permit and the roads are found to be available for touring, that the scouting party instead of terminating the trip at Nashville will continue to Memphis and New Orleans by the way of Birmingham, Meridian and Jackson.

A more desirable route to New Orleans has been sought by many motorists as that city is visited annually by thousands of travelers, especially during the Mardi Gras festivities. It has even been suggested by several prominent automobilists and good roads advocates that a popular tour to New Orleans under the auspices of the Touring Club might be organized for that novel and world-renowned celebration.

From New Orleans the Touring Club's representatives will return to Atlanta, visiting Mobile, Montgomery, Ala., Columbus and Macon, Ga.

News of Shows, National and Local

SOME 300 men representing two score trades were put to work in Madison Square Garden, Thursday, for the Twelfth National Automobile Show, which opens Saturday night, January 6.

W. W. Knowles, who is in charge of the work of decorating the Garden, has groups of men at work in all parts of the big amphitheater and they are to labor night and day up to the opening hour of the show. Gangs of iron-workers are now installing the big girders which are to support galleries.

Practically all of the sculptor work and the scenic paintings which will be used in the decorative settings for the exhibits are now ready to be set in place. Carpenters and wood workers are engaged in the construction work of the booths and ornate wood effects.

The arena floor was put down several weeks ago. In a vacant office building in this city more than 200 women are sewing together the carpet which is to be used to cover the space of the exhibits. Twenty carloads of furniture which is to be placed in the booths of the exhibitors has been delivered at the Garden. Two monster elevators which are to be used to hoist the cars and accessories to the balconies will be installed in a few days.

Last week, while the roosters were crowing on the main floor during the poultry show, men were at work in the basement cleaning and painting and covering the walls and pillars with old-gold paper. The basement, with its bodega set in Southern California scenery, is practically finished.

The exhibition hall, which is to represent a realistic outdoor Spanish garden, is now receiving the attention of the decorators, as is also the Japanese cherry garden, which will be the theme of decoration in the concert hall.

The Garden will be opened daily to the general public from 11 a. m. to 11 p. m. During Part I the garden will be open from noon, Friday, January 5, to 6 p. m., January 6, for the installation of the exhibits, at which hour these will be in place. No exhibits or goods will be admitted into the building after 6 p. m., Saturday, January 6. All goods will be received and shipped from the Garden at the corner of Twenty-seventh street and Fourth avenue. No goods will be permitted to be brought into or removed from the building from any other entrance. A clerk will be stationed at the entrance of Twenty-seventh street and Fourth avenue to check in all receipts of goods.

Grand Central Palace Show Final Plans

While it has been customary for the promoters of automobile shows to expend thousands of dollars on decorative features, the coming event at the Grand Central Palace, which opens to the public at 8 o'clock on the evening of January 10, will not be one whit behind anything ever attempted in this city in the line of beautiful setting.

To persons accustomed to the gloom of the old building at Forty-fourth street the new structure, which is in every way deserving of the name given it, will prove a revelation. It is one of the most beautiful things, from an architectural viewpoint, in New York. Its massive columns, beautiful marble trimmings, hard maple floors and accompanying splendor are probably of higher class than have ever been attempted in a building of the size and designed for the same purposes.

The management of the coming show, attended by the best scenic artists of the city, spent a great many days figuring on the scheme of decoration and equipment, agreeing after every session that to attempt anything of the sort would be akin to painting the lily. As a result of these deliberations there will be placed in the Palace nothing of the gaudy material usually designed to cover the unsightly spots of public buildings—nothing, in short, which can be properly described as anything short of the finest forms of artistic production.

Mural paintings will predominate. They will be used liberally, but rather because the public expects this sort of thing in connection with an automobile show than because it is a necessity. The moment one enters the building the effect will be that of an Italian garden. The main floor is approached by means of a flight of marble steps, 60 feet in width, decorated with brass railings and trimmings and ornamented for the occasion with bronze emblems, typical of the progress of the industry and growing palms of great height and size. On the center of the floor, where the exhibition spaces are large and will contain some of the finest productions of the industry, there will be absolutely nothing in the form of decoration, except the necessary signs, on which a great deal of care has been exercised, and the floor covering, which is of wood carpet, so made and laid that it may be cleaned and polished every night after the show has closed.

There will be none but passenger cars in these sections. The scheme of decoration commences at the walls. Every window is to be draped, to exclude the glare of light inseparable from a building so liberally furnished with windows. The space between the windows, extending to the ceiling, will be entirely hidden by paintings by one of the city's best scenic studios.

Some of these paintings are of mammoth size, as, for example, a canvas 60 x 50 feet, depicting the effect on a herd of centaurs of the appearance on the scene of a modern motor car. This work of art will perhaps be the most interesting study of the collection. These spaces will be occupied almost exclusively by passenger cars, though there will be a couple of the more important exhibits of commercial vehicles also, and care has been exercised to harmonize the color scheme with the bodies of the cars to be shown.

The second floor has been similarly treated, so far as walls are concerned, but around the front of the balcony will be placed fifty or more marble vases filled with poinsettias and green foliage. The center of the third floor is separated from the main building by trellis work of great size, which will be completely covered by foliage and flowers, the whole presenting a scene of rare beauty, viewed from any direction, but especially from the main entrance and lower floors.

The size of the Palace makes it particularly desirable for the holding of an exhibition of the kind. It has a greater amount of exhibition space than any other show building in America. The exhibits at the coming show will cover 138,000 square feet of space.

The noisy demonstration of horns and other alarms which have characterized some of the automobile shows of the past will be absent at the show. The management has made a rule that no horn will be permitted to enter until its reed has been removed and that no other form of alarm may enter the building until it has been so altered that no sound can be emitted by it. Exhibitors have shown a disposition to obey the rule, regardless of any further action by the management, by written assurances that they will follow the rule in letter and spirit.

One of the difficulties heretofore experienced by automobile show promoters has been keeping the floors of their buildings free from dirt. The enormous crowds constantly walking over the carpets have left indelible stains which have been unsightly.

This will be overcome at the show at the Grand Central Palace. A floor covering is to be used, consisting largely of wood painted to suit the coloring of the cars, which will be washed and repainted after the close of the show each night, so that the floor will at all time be inviting and in keeping with the magnificent details of the remainder of the building.

For the first time in 7 years the people of New York and the thousands who come to New York for the annual automobile shows will be able to examine all of the cars of importance made in this country the same week. Heretofore trade rivalry made this impossible. The show at the Grand Central Palace has for several years been held a week ahead of the Garden show in the hope of getting first attention at the hands of the public and the press. This year the strenuous rivalry that has heretofore characterized the shows is absent. Patent suits have passed into oblivion and the only reason two shows are to be held is that no one building in New York is large enough to accommodate all of the manufacturers.

Many thousands of people will obtain their first glimpse of the new Grand Central Palace. To those who still have the old building of the same name in mind, the new structure will prove a revelation. It is located two blocks north of the old Palace, at Lexington avenue and Forty-seventh street.

Quakers to Show Amid Splendors

PHILADELPHIA, Dec. 26.—When the doors of the First and Third Regiment Armories are simultaneously thrown open for Philadelphia's eleventh annual automobile show on Saturday evening, January 13, an attraction second in interest only to the exhibition itself will be the decorative scheme employed, without a doubt the most pretentious thus far conceived for a Philadelphia show. Charles T. Ashman, whose departure from time-worn methods formerly used, scored a hit last year, will again have charge of this feature.

The Third Regiment Armory, Broad and Federal streets, will depict a scene in the forest of Fontainebleau, France, the main decorative fabric along the eastern side of the building showing the depths of the forest in an autumnal sunset, approached from either side by a drive, representative of the road from Paris, in which driveway will be pictured automobile parties on their way to the forest. The north, west and south walls will be a series of panels presenting French scenes. As was the case last year, all unsightly woodwork and obstructions will be cleverly concealed and by suspending from the ceiling by means of an invisible wire, the individual signs designating the various exhibitors' booths, impediments to an otherwise sweeping view of the whole room will be eliminated.

At the First Regiment Armory, Broad and Callowhill streets, a scene will be presented of the approach to the Castle of St. Elmo, embracing a panorama of the Bay of Naples, the Italian Riviera, Mt. Vesuvius, Sorrento and the island of Capri. The side-walls will be decorated in balustrade effect, supported by a stone wall, overgrown with moss and plants, and dotted with trees.

The color scheme will be carried out in harmony with the surroundings, and as at the Third Regiment, suspended electric signs will be employed so as to furnish an uninterrupted view to visitors.

Rhode Island Show in Palm Garden

PROVIDENCE, R. I., Dec. 26.—A particularly attractive decorative scheme has been worked out for the interior of the State Armory, Providence, during the week of the automobile show to be given by the Rhode Island Licensed Automobile Dealers' Association January 22-27, inclusive. The exhibition, which is the first in three years within the state, promises to be a record-breaker.

The general effect will be that of open-air palm garden, and an azure sky will be manufactured out of cloth, hung just above the girders of the shed.

All of the exhibition space has been rented.

In the upper, or main hall, the pleasure vehicles will be shown. The basement hall, where the artillery companies are quartered, will be used for commercial vehicles and accessory displays. Forty-three different makes of pleasure vehicles will be shown in the main hall and sixteen styles of commercial trucks or delivery wagons will be found in the basement section.

Bird Concert at Syracuse Show

SYRACUSE, N. Y., Dec. 23.—Automobiles worth $500,000 and $150,000 in accessories will be represented at the third annual show of the Automobile Dealers of Syracuse at the State Armory in March. Every exhibitor will be expected to insure his display; and a wise precaution, worthy of general imitation, is a requirement prohibiting any gasoline or explosive in the hall. Machines running thither under their own power will be required to have their gasoline siphoned out before being taken inside.

There will be an immense fountain, electric showers of lights in fine designs and the "bird symphony." The latter feature is borrowed from the recent industrial exposition here. From the center of each first floor booth will be suspended a birchbark basket cage containing a canary bird, all picked songsters. The success of this "concert" at the former affair has dictated its repetition.

Space Allotted for Boston Show

BOSTON, MASS., Dec. 26—Chester I. Campbell, manager of the Boston automobile show, who is just back from a tour of the European shows, says that he did not see anything there in the line of decoration and arrangement that seemed original enough to be adapted to the Boston show.

Now he is busy with the plans for the March show, which this year will last two weeks, the pleasure cars being housed in Mechanics' building the first week and the commercial vehicles the second week. Practically all the space has been allotted and the dealers are able to get some idea of how much room they will have in which to show their models.

Detroit Space All Under Contract

DETROIT, Mich., Dec. 26.—Space in the Wayne pavilion and temporary annex, for the eleventh annual automobile show of the Detroit Automobile Dealers' Association, is now all assigned, the final drawing having taken place last Friday night.

There were forty-three applicants for the 10,000 additional feet of floor space afforded by the annex, and most of them were taken care of, although some of the exhibits will be somewhat cramped. There was a large representation of motor car manufacturers at the drawing and this branch of the industry will make a very creditable showing at the exhibition.

Work on the annex will be started next week, and will be rushed.

Atlanta Show Will Be February 10-17

ATLANTA, Ga., Dec. 26.—The Atlanta Automobile and Acessory Association will hold its first automobile show February 10 to 17, in the local Auditorium-Armory, where the first and only national Southern show was held a couple of years ago.

As a result of a series of meetings it was decided to hold the show and to pay for it by charging exhibitors 50 cents a square foot for all space used. This, it is estimated, will pay all expenses. Then all receipts from other sources will be divided among the exhibitors.

The committee appointed to arrange for the show was H. G. Moore, manager of the Atlanta Velie Branch, chairman; W. D. Alexander, of Alexander-Seewald Co.; D. T. Bussey, of the Georgia Motor Car Co.; Charles L. Elyea, of the Elyea-Austell Co.; F. T. Long, manager of the local Cole branch; John E. Smith, Pierce-Arrow agent; Wyllie West, manager of the Firestone branch, and Frank P. Day, manager of the Locomobile branch.

The committee is now soliciting the field and expects within a few days to sell all available space. In the meantime a manager will be appointed and actual work begun.

The curbstone brokers, against whom there has long been a bitter feeling in Atlanta, will be barred from the show and no cars except those represented by members of the association will be allowed in the exhibit.

Sliding Space Scale at Baltimore

BALTIMORE, Md., Dec. 26.—A. S. Zell and H. M. Luzius, constituting the committee on floor space for the Baltimore show to be held in the Fifth Regiment Armory, February 20 to 28, inclusive, under the joint auspices of the Automobile Club of Maryland and the Baltimore Dealers' Association, plan to have three sizes of floor space. These will be the minimum, intermediate and maximum. The dealers will be notified to file applications before January 20.

After that date the space in the Armory will be reckoned with that required by the dealers and if the Armory floor is not large enough, each applicant will be reduced on a percentage basis. The dealers will then be notified of their spaces and also the date for drawing.

Show at Canadian Capital

OTTAWA, Dec. 26—The Ottawa Valley Motor Car Association is working hard to make its first annual automobile show a great success. Already nearly all of 40,000 square feet available has been sold and the exhibition promises to be complete in every detail.

Canada's crack band, the Governor General Foot Guards Band, of 50 pieces, will furnish music. The opening promises to be an event. The House of Parliament will be in session during the week and the fact of nearly 500 members of the house being here at that time, from all over the Dominion of Canada, apappeals greatly to exhibitors, as many customers and prospective buyers of automobiles will be tempted to attend the show.

Arrangements are being made for special nights with special attractions. Manager Louis Blumenstein is busy allotting space. The decorations will be in the handsomest and most striking that can be obtained.

Hudson Terminal as Show Place

Down in the concourse of the Hudson terminal building in sight of thousands of Jersey commuters the Abbott-Detroit Motor Company has placed an Abbott-Detroit car of latest model and a Regal colonial coupé. The two cars attract much attention and have provoked many inquiries.

News of Other Local Shows

DENVER, COL., Dec. 26—Plans for the Denver automobile show, which will be held in the Auditorium March 4-9, are being rapidly matured, and from present indications the exhibits will exceed those of any previous year. So heavy is the demand for floor space that it will probably be necessary to build an additional display room in the street adjoining the Auditorium. The Studebaker exhibit will be sent to Denver entire from the New York show and other dealers are planning special features which will not be ready for announcement until later.

ELMIRA, N. Y., Dec. 26—The second annual show will be held at the State Armory, February 26 to March 2. The entire main floor space has been sold and 34 different makes of cars will be shown. Great interest is being taken in the forthcoming show. One of the features will be the decorations. The entire basement will be given over to accessories. Louis Blumenstein has been appointed manager.

SIOUX CITY, Ia., Dec. 26.—The Sioux City automobile show will be held from February 26 to March 2. The date was chosen at a meeting of the Sioux City Automobile Dealers' Association, last week. This date was selected as it follows the Omaha and Minneapolis shows, and precedes the Des Moines show.

TROY, N. Y., Dec. 26.—The Troy Automobile Club will hold its second annual show at the state Armory, Troy, during the week commencing Monday, February 12, and all indications point to it being one of the biggest and most spectacular events of this character ever held.

HARRISBUBG, PA., Dec. 26—The third annual automobile show of the Harrisburg Automobile Association will be held at the Arena February 3 to 10. There will be exhibits by automobile dealers and dealers in tires and automobile accessories.

Particulars in Lozier Cases

A sharp check has been given to the proceedings filed by Fletcher R. Williams and Joseph L. Rhinock against the Lozier Motor Company, charging breach of contract to sell control of that company. The New York Supreme Court has entertained a motion to require the plaintiffs to file bills of particulars in the actions, specifying the nature of the contract and all its circumstances.

It was planned to have the cases tried on their merits this month, but the court order requiring amendment to the complaints may have the effect of deciding the case in the Appellate Court as the attorneys for the plaintiffs have the right to appeal from the order of court to file bills of particulars and the upper court may then take jurisdiction of the matters on the law point raised.

According to the attorneys for the Lozier Company this will probably be the result. Under the circumstances the plaintiffs are ordered to file the particulars immediately or take appeal and the latter course is considered more likely. The pleadings so far submitted tend to show that Williams was not the sole financial man involved in the alleged contract of purchase, but that George B. Cox, of Cincinnati, was also interested. Rhinock figures as an agent in the suit.

Bars Unnecessary Noise

Chicago has placed the automobile horn in the same class with locomotive and street car signals by creating a law forbidding their use save as a warning of danger. Moreover, the city has taken another step forward by defining, for the first time in the history of municipal legislation, just what an adequate automobile signal is, by providing that no device shall be used as a signal of warning save that which gives an abrupt sound. This means that, no matter how much noise might be made with a warning signal, to make other than an abrupt sound will put it in the power of the court to fine any person guilty of unnecessarily sounding his signal $25.

N. Y. Car & Truck Co. Declares Dividend

Creditors of the bankrupt New York Car & Truck Company will receive a small remembrance about New Year, as a dividend of 2½ per cent. has been declared by the receiver of the defunct company. The claims that will participate foot up $151,000 and thus the amount to be distributed is about $4,000.

One of the largest claims in litigation against the company is that of the Allen-Kingston Motor Car Company, which is suing for about $25,000 for breach of contract.

Trials of the Non-Technical Scribe

HIS head was swirling in a seething mass of figures. They looked and felt like two dozen W. W. equilibrators somewhat tangled and bumping from one thought wave to another, and every bump jerked loose something in his delicate cerebrum. He was a reporter, just then, and he had been sent out to get a special story on "The Ambitions of the Automobile Industry." He had just emerged from ten minutes with Mr. Alpha, five minutes with Mr. Beta and fifteen hard minutes with Mr. Omega, these being the gentlemen who are duly appointed to say the first, the second and the last weighty word on the greatness of everything self-propelled. Handing out some nicely typewritten schedules to assist the faltering memory, each of them had managed to convey the impression that a great deal more was true than could be put into type and figures; these were simply safe, conservative estimates based upon a personal and thorough canvass. As for the future, the figures would probably be doubled in another year, as they were so much below the facts to-day. Ambitions? Oh, yes, he had asked about ambition. Well, what more could he want! Here it was.

"Suffering Amphortas!" exclaimed the young man—for the shrewd city editor always sends out a young, enthusiastic man when he wants an unvarnished story for a campaign review—"300,00 automobile wage earners in Detroit alone; a total invested capital of $891,345,221.46; 197,315 motor vehicles produced in the fiscal year ending—well, would not that roll you over?—2,152,023 pneumatic India rubber tires aggregating a market value of $186,245,789.20. Hold my hand! I am sure going to spring these numerals on O'Shaughnessy before they go to the desk."

O'S. turned out to be a United cigar clerk with orders to say "thank you as if he meant it" when handed good money. Privately he considered himself in training for a position as trust magnate and handled coupons with a fond, clinging touch. "Ben," he said, when confronted with the automobile magnitudes, "don't you try to hand out those figures for hot stuff. They are not in it with ours. Look here." And he pulled out a strip of cigar statistics from a notebook. The figures were decidedly longitudinal. "Take my word for it, Ben, old man, you are in wrong. Figures don't stagger anybody any more. I have turned loose these," and he waved the strip, "on lots of fellows who come in here. No go! And they are longer than yours. One fellow who buys twofers on Fridays and twofer quarters on Mondays just gave me the ha-ha. He said 'They have got machines now for turning out them statistics, I hear, and longer ones than that.' No, Ben, go and get another story."

O'S. was Ben's trial public, and Ben took the hint. What he handed to the city editor was something different. It was a chain of interviews with automobile owners, but it was never printed. "Put it somewhere else," the old man told Ben, handing him back the copy instead of shoving it into the hamper for superfluities; "it does not go on this sheet. What else have you got?"

Ben had conceived the brilliant idea of hunting up half a dozen young Tech chaps who owned automobiles, and his fraternity pin had eased matters along. "Whatever they think is the matter with the automobile industry it ought to be up to the automobile industry to change, and I can get my dope that way. I can't help it if they are not ambitious; they ought to be. Whoever heard, anyway, of any soulless industry having ambitions? It is the wrong cue." Ben was quite sure that the young chaps were just the right kind of persons. They did not care much for figures—"'lay figures' don't go with me," one of them said in his young technical pride—but they claimed to be very strong on facts and they were exceedingly liberal in wanting things done differently. What they had told him was Ben's copy, and it was very long. "How near straight is it?" he was asked. "Too near," Ben replied with a droll tinge of sadness; "I don't know much about it myself, so I could not have prinked it up if I had wanted to. It's sure the voice of the public, if there is one." Old people do not count in Ben's estimation.

With liberal omissions, the gist of the remarks of his various authorities is condensed in the following: "An industry does not interest anybody except those who are in it or expect to get into it. It is the art of building automobiles and the progress in getting better and better results for the benefit of the user that interests the public. Some very fine problems are involved in making 10,000 automobiles with a capital of $10,000 and making them all alike and selling them at a profit at $1,000 for each and having each of them better than anything that could be bought for four times more money four years ago, and all those things. But there has to be division of interests in this world, just as there has to be division of labor, unless one is willing to split oneself up into atoms. An individual's interests cease distinctly when nearly all the things that are done are aimed at money-making for the other fellow and every improvement is pushed aside because it interferes with the regular routine of manufacture. The other fellow is vitally concerned, of course, as are all those who are to share in the profits. A little glow of satisfaction can even be derived from reflecting that the time is drawing nearer when every farmer and every expressman will be able to buy a car to help him out in his business. But every one can't be in these lines. Meanwhile it would be much more interesting to learn that, for example, a plan had been devised for doing away with the gasoline tank. Someone might get up a standard size of gasoline can—to hold three gallons, say—and have that sold all over like sugar, only sealed; and provide a couple of cradles with clamps for holding these cans in each car and an attachment with a nut and a pipe or anything to enable one to draw direct from either can. When one can was empty start drawing from the other and at the next stopping-place simply exchange the empty can for a full one. There would be decidedly less bother pouring gasoline or getting it dirty or full of water, and there would always be some on tap. The cans could be removed at home and the owner could store his car where he pleased without getting into trouble with the insurance people."

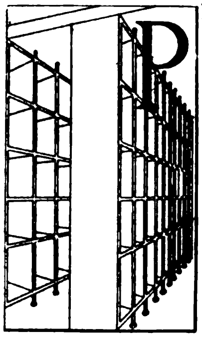
"No use," said Ben to himself, "to ask these people if the special machine tools which they get up for producing 10,000 cars in a series and at low price don't sometimes make better cars as well as more of them, but I will ask the next fellow, and if he makes another kind of a break I will take that up with the third man. When I get to the end of the string, I think I shall have something that way."

Hoosiers Raise License Rates

INDIANAPOLIS, Dec. 26—A new motor car license ordinance has been passed by the city council of Indianapolis and has been approved by the mayor. After January 1 the following fees will be charged annually: Three passengers and under, $5; four passengers and over, $8; private and public buses and delivery wagons and trucks of more than 1,000 pounds capacity, $15; delivery wagons and trucks having a capacity of 1,000 pounds or less, $10. The present license fee obtaining in the city of Indianapolis is $3 for all classifications of self-propelled vehicles.

Reserve Parts Stock System

How the New York Service Department of the Mitchell Motor Car Company Arranges Its Spare Parts to Advantage, with an Up-to-Date Inventory Always at Hand



PRESUMING that the repair or service department of a company is organized and conducted rather with the object of increasing the comfort of the company's customers than to profit on the work of the department itself, the importance of an all-embracing system makes itself evident at once. A service department, if it would render quick and effective service, must contain several pieces of every sort of part used on the company's automobile. This sounds fine enough, but when one remembers that there are some 3,000 different parts comprising the make-up of the average automobile, the situation immediately takes on a different face. The man who has never entered in the stock room of the repair department has no idea of the amount of material stored and handled there, and what is most important, kept in good order. Unless he keeps this point before him, at all times, the vastness of his stock will avail nothing to the department head either and will not tend toward his success. It should never be forgotten that the service department is a small factory, and, as in a factory, space, time and labor must by no means be wasted in the process of conducting the business of the enterprise.

The principal difference between service department and factory lies in the part played by labor in both cases. In factory work labor is by far the most important of the three items named above. Even if space and time are not utilized as they should be, with a certain loss of labor as the result, this fact will hardly ever determine the success or failure of a factory's operation. But in a service department the situation is different. Unless everything is kept in the most painstaking order, too much time will be lost in looking for the parts sought, with a consequently large loss of both labor and business. Lack of systematic arrangement has been the cause of failure for more than one repairer, whereas the introduction and maintenance of a thorough system has done much toward conducting a repair department without a loss, sometimes even at a profit, and producing a satisfied clientèle in the case of many a successful company.

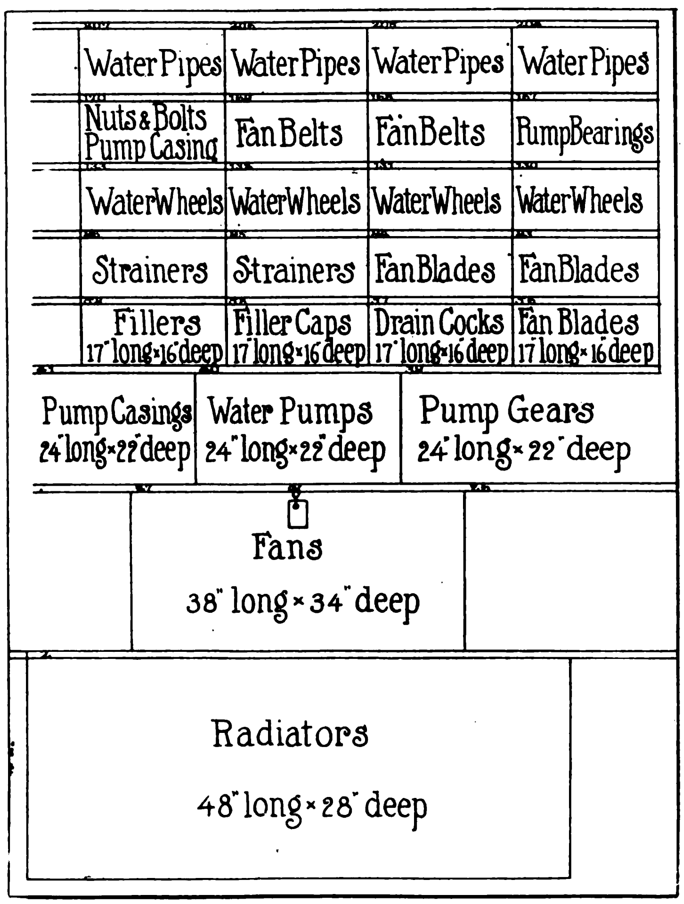


Fig. 1—Arrangement of parts of cooling system in the Mitchell storeroom. The height here illustrated is full in proportion to the width

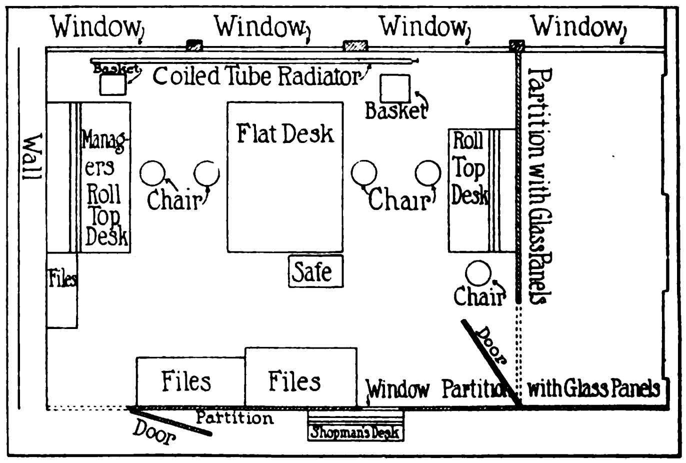

Fig. 2—The office of the stockroom is located adjacent to it and so furnished as to permit a maximum of light to find its way to the storeroom proper

The Mitchell Motor Company, which has just moved its New York service department to 41 West Fifty-fifth street, has installed an adequate system there. Of course, some system had been used in the old quarters of the company's repair department, but experience showed that it could be improved in many respects, and when the department's location was altered the management used the occasion to introduce many innovations and improvements in their system of keeping the stock of repair parts in order. It had been found that an eternal inventory was a desideratum, but a system leading to it could not be introduced while still in the old quarters. Moreover, during the past few years many improvements in the arrangement of the parts had suggested themselves to the management. All these new ideas were carried out in the new building, and when the rush of work came on right after the place was thrown open to the Mitchell clientèle, the increased efficiency which made itself felt at once proved the wisdom of the departures made by the management.

The offices of the stockroom and the parts storeroom are located on the fifth floor, and the arrangement of each is seen in Figs. 2 and 3 respectively. The desks in the office are so placed as to keep as little light as possible from entering the storeroom adjacent to it, and for this purpose a flat desk is used in the center of the room, while the manager's roll-top desk and one more desk of this kind are placed against the wall and the partition near the elevator, respectively. As Fig. 2 shows, the entire front of the room is of glass windows reaching from about 2 feet above the ground to the ceiling and permitting plenty of light to enter, especially since the buildings on either side of the street are not high enough to keep the light away from these windows. A coiled-pipe radiator runs along almost the entire length of the window, providing enough heat in winter time. No space is wasted in the office, and only as many files are kept there as are necessary. Likewise, two waste baskets are all that are provided, and, besides the chairs for the force, a small safe is all that remains to be mentioned of the equipment of this room.

A swinging door leads from the hall space into the office and another door of the same type thence to the storeroom. This place has a perfectly workman-like appearance, and resembles an office in no respect expect that a small roll-top desk for the foreman is located next to the partition separating office and storeroom. The rest of the arrangement used in this room is

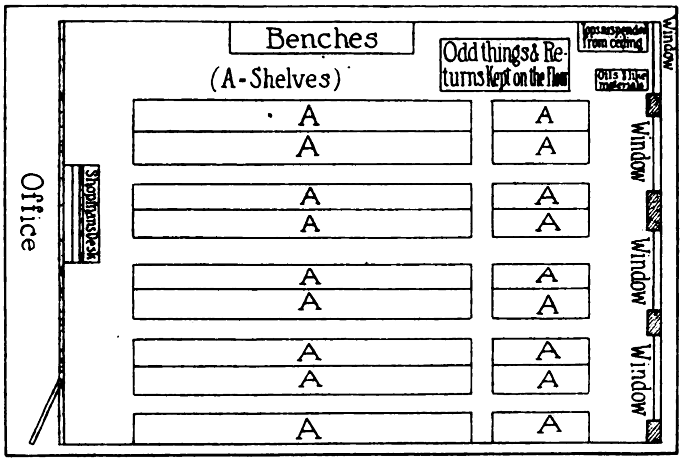

Fig. 3—Floor plan of the room in which the repair parts for all models are kept, showing the advantageous arrangement of shelves for storing the parts

shown in Fig. 3, indicating the position of shelves and working benches, as well as the places where large parts are kept. There are practically seven rows of shelves, each 13 feet high. The total length of each shelf series is about 65 feet, while the depth of the shelves varies. The compartments nearest to the ground have a depth of 34 inches, while the following higher rows are 28, 22 and 16 inches deep, respectively. This latter figure is the minimum depth; that is, upward from about 6 feet above the ground every compartment extends that distance in from the front. The variation in depth is noted on the diagram of a number of shelves illustrated in proportion to their actual size in Fig. 1. Here is also seen the idea embodied throughout the stockroom in regard to the arrangement of parts. The large units of the automobile, such as assembled motors, transmissions, differentials, radiators, and so forth, are kept in the bottom row of shelves, while the parts making up these units are stored in the compartments above. Fig. 1 shows clearly how this idea is carried out. Above the assembled-radiator compartment fans and pumps are stored, which are followed by filters, filler caps, fan blades, strainers, pump casings, fan belts, bolts and nuts for the cooling system, etc. The leading motive in this arrangement is weight, and, to a secondary extent, importance of the parts.

Each compartment or bin is numbered, and the numbers run from one end of the row to the other, and back in the next row above. The numbers of the assembled units bear no relation to the numbers of the parts stored above them, but the only relation there is is contained in the relative position of the bins. Passing from the office end of the row next to the working benches, cooling systems fill up about one-third the length of this row. Every bottom bin contains a radiator, and the various parts of the systems are stored in the upper bins. The rest of the first row, before reaching the aisle seen in Fig. 3 is devoted to carburetion and ignition. With carbureters arranged in the two bottom rows of compartments, and all such parts as go to complete the gasoline-air mixing and transporting system, as butterflies, inlets and outlets, piping, draincocks, throttle levers and rods, about half of the shelf row is filled. The remaining portion of the first row is used for storing magnetos and various ignition sundries, including wiring, batteries, terminals, sparkplugs and so on.

Passing through the aisle and coming back along the row of shelves backing the first, the storage place for wheels and their parts is next to the aisle, while springs take up the next section of the row, with leaves, bolts and other suspension parts located in the higher-up compartments. The steering system fills practically the rest of the row. Completely assembled steering gears fill up a number of ground bins, and above them a place is provided for steering posts, sectors, steering knuckles, drop arms, bolts and all the other members of the system which makes up the brain of the automobile. Body parts are filling whatever space is left of this row, and this class of material is continued in the next row, where reserve seats, leather hood-straps, doors and door-locks occupy advantageous positions. The bottom bins of this row are mostly filled up with tire siderings, while on top of the shelves mudguards are located. Front wheel parts are next in the arrangement, hubs and wheels being stored in the lower bins, with bearings stored above them and the top compartments filled with such smaller accessories as front wheel bearings, oil-cups, balls, races, hub-caps, etc.

Transmissions hold forth in the next row. Complete gearsets, assembled in their boxes, are stored in the two rows next to the ground, all of them being neatly arranged and placed beside one another, so that no difficulty nor loss of time is encountered when one of them has to be taken out of the store. Transmission housings and shafts are found directly above the com-

Fig. 4—Sample of an inventory card such as is attached to each bin. If entries on this card are made conscientiously, it will prove very efficient

plete sets, being followed, as the eye strays upward, by gearwheels and bearings on which the transmission shafts run, not forgetting nuts and bolts holding the working members together.

An inspection of the following row reveals the arrangement that has been evolved to store crankcases and other heavy portions of the car to the best advantage. Crankcases take up so much space that some of them are kept in front of the shelves, while several ground compartments are filled with them. Brake systems, consisting of brakes, brake drums, bands, rods, pedals and levers, brake lining and smaller parts occupy the remaining length of the row.

In the sixth and seventh rows rear axle assemblies and elements are stored. Complete assemblies are, of course, kept in the bottom bins, as are rear axle sections, drive and jack shafts, while differential gears and housings, bearings, bevels and pinions, torsion tubes and extensions are stored above the heavy parts, and to fill some spaces in this division muffler parts and fender brackets have also been located here.

Across the aisle, beginning with the seventh row, engine cylinders are stored in the lower bins, while mufflers and muffler parts are kept above them. Accessories of a varied nature, such as sponges and chamois, have not been forgotten. In the following rows oilers, pumps, muffler shells, tire brackets and flexible tubing are found, whereas complete mufflers are kept on top of the shelves. Windshields and their parts are stationed on the floor adjacent to the windows, and this holds good also for a number of axles and shafts which are not so dimensioned that they can be stored in bins. Again the small components of the units mentioned are stored in the spaces above them. The rest of the short rows contain engine parts, crankshafts, camshafts, tappet rods and valves, clutches, starting cranks and straps, water jackets, connecting rods and other members of the power plant. Tire rings are stored in some of the bottom bins, with tire cases next to them, and such parts as brackets, both for tires and lamps, in the higher bins. Side levers and parts follow, and then comes a supply of inner tubes. Care has been taken to keep all rubber goods in a position well protected from the light. Whatever space is left is occupied by thrust bearings, foot levers and pedals, acetylene generators, cardan shafts, universal joints and elements of the latter.

Between the shelves and the wall, next to which the benches are placed, various material is stored. Many of these things are faulty parts returned and replaced under the guarantee, and others special equipment not included in standard cars. Oils, tire healing compounds and similar things are kept on a narrow shelf near the window, and facing them tops are suspended from the ceiling, one close to the other, avoiding all waste of space.

Beside the material kept in this storeroom there is a number of rear axle assemblies for which there is no room in this department. They are kept in a place two floors below the stockroom, where also a number of chassis are stored. But the bulk of the repair parts, in fact, everything that may be needed every day in the year, is kept in the regular stores on the fifth floor.

The special and live inventory system of the Mitchell company has yet to be described. It consists of cards, Fig. 4, one of which is hung on a nail above each bin, and on which the quality and quantity of the bin's content is noted. Fig. 5 is an actual reproduction of a card used on compartment No. 69, in which waterwheels for the circulating pump are stored. When stock was taken on October 20, the day after the company had moved to the new building, eighteen waterwheels composed the stock. This state of things, however, was changed when eight days later a waterwheel was taken out of the stock, to be used on sales order No. 17,823. This sale was not done on a new car, but it was really an order for the repair part sent in by an out-of-town Mitchell agent, who required the part for one of his customers. The so-called sales order generally does not contain the name or description of the part, but only the part number, which in this case is J-51. The mark R. T. S. 1909 refers to the model and year of the machine for which the waterwheels kept in this compartment were designed.

On October 30 another waterwheel was taken out of stock, reducing the number of wheels to sixteen. Meanwhile an order has been sent to the factory and Racine, Wis., to send a fresh supply of four waterwheels, which arrived on November 6, as may be seen by referring to Fig. 4. Within one week three wheels were again ordered by sales agents, but then a new shipment arrived, which increased the number of parts in stock to twenty-five. On the following two days one pump each was taken from stock, these times to be used on a repair order done on the premises.

Referring to the spaces on the card not filled out in the illustration, their purposes are as follows: Under the heading On Order the number of reserve parts ordered from the factory are entered the day when the order is sent there, and the number of the order sent to the factory is also noted. The reason for these spaces not being filled out on this card is that the parts which afterward came in were ordered before the company moved to its new quarters, and there started a new inventory.

Several times a year the number of parts in stock, which is entered on each card, is noted and the results of this work compiled by the office. For this end no book is used, but a card file with plain cards on which the part number, model and year, date of taking stock and amount of parts taken are written. By the use of the cards, Fig. 4, the work of correcting the file is very easy and may be done by two men in about two days.

While the inventory file is kept in the order of parts, letters and numbers, another file serves as a key to an initiate when he has to look for a part while no one is around to tell him where it is to be found. Supposing the man needed a bearing for the crankshaft on the 1911 Model T touring car. Looking under crankshaft bearings he consults the 1911 card and there finds for Model T the number 2,357. All that he has to do now is to go to the bin thus numbered, take out a bearing and make a note of the fact on the card. The whole operation takes less than five minutes, and with a man of average intelligence, if he has once been told how to use the system, there is no chance of an error in his handling it.

The total number of bins in the Mitchell stockroom is 2,853, and despite this large number the simple and yet elaborate system makes mistakes very improbable. There are 8,136,756 chances of making a mistake by misplacing parts in the storeroom containing 2,853 bins, but it is only due to a poor system or poor workers executing it if any of these mistakes happen. Naturally, when mistakes start in and increase, things must in course of time reach a state where the system is not worth anything. But in this case the remedy would lie only in the getting of the proper men capable of executing it and willing to do so. It must be remembered that even where a good system is introduced the personal equation plays its part, since it takes persons to handle the system; but since this is the case, failure, if it occurs, must be charged up to the factors that bring in the personal equation, and not to those which tend to do away with it.

Blushes Deeply When Too Hot.—A paint that sticks well to metals, or to most of them, and changes from a pink to scarlet, then to maroon and finally to black, as the temperature of the metal rises from ordinary to 50 deg. centigrade, to 70 deg, and to 85 deg., and which goes back to its original pink when the metal cools, is among the recent inventions of German chemists. It is offered under the name of "Efkalia," by Franz Korn, in Halle an Saale-Trotha. It may be applied on top of other paint and seems to promise a wide utility as a warning signal and heat indicator for spark plugs, cylinder heads and anything in factories which may run hotter than it should. It is stated that several fire insurance companies have taken it up. In suitable applications, it may evidently be used for experimental work, as for a ready determination of the operating conditions under which an automobile motor wastes or does not waste the calories with which it works, or for determining the efficiency of radiators or other cooling provisions.—From *Metall-Technik*, Oct. 28.

Peeps Thro' Goggles at Distant Lands

NOTWITHSTANDING the rapid increase in automobiling in India, a most disturbing inconvenience lies in the difficulty which owners experience in obtaining spare parts from Continental European manufacturers. In some instances it has been necessary to wait three months for the arrival of parts. It is suggested that the waiting-time might be cut down materially by the registration of one's motor car and the coining of a mutually understood code between the manufacturer and buyer at the time of purchase, that needed parts might be cabled for.

Glasgow has just gone on record as having accomplished two acts of public service. The authorities have dispensed with every horse in the fire department except two, the horse-drawn engines having been replaced by motor-pumps; while the old horse-drawn prison van has given way to a modern motor-van, which is doing regular corporation service.

Following close in Glasgow's footsteps come Leeds, Manchester, Birmingham, Liverpool, Belfast, Dublin and London. In the first named six cities changes are being pushed gradually, motor-pumps crowding out the horse-drawn engines. In London the march of modern ideas is swifter. It was only at the last meeting of the London County Council that an appropriation was made and tenders called for to supply the fire department with thirteen motor-pumps. City authorities declare that within ten years there will not be a horse-drawn fire engine in any of the large cities of England, Ireland or Scotland.

Herr Von Dallwitz, Prussian Minister of the Interior, has just issued a decree declaring the blowing of motor-car horns as unnecessary, either by day or night, and accordingly he regards the making of such noises as a breach of the peace and as a misdemeanor, and he will see to it that offenders meet with punishment fitting the alleged crime.

A German has taken out a patent for warming the rugs or carpets on the floor of the automobile. The contrivance involves a series of wires which run through the carpet and the current being turned on, the result is a sufficient amount of heat to keep the passengers' feet comfortable in the winter.

A short Bill for amending the Motor-Car Act has been introduced into Parliament, which will relieve drivers of automobiles of the necessity of taking out duplicate licenses. Men are obliged, under the present system, to take out a police-driving license, in addition to the ordinary license from the City Council, a fee being exacted in both cases.

The British Government is still extending the use of the motor-car for the conveyance of mails. Over one hundred services or sets of services are now being performed, by motor-car vans. During the year important services of this kind have been established between London and Portsmouth, London and Birmingham, Glasgow and Greenock, Dublin and Kells, etc. The motor-vans have replaced horse-vans in a number of services in London. The postal authorities admit that the greater speed of motor as compared with horse traction is of considerable advantage to the mail service.

During the year just ended, 800,000 gallons of tar were used on the county roads of Kent, England. The cost was over $100,000. In addition, ninety-one tons of bituminous binding preparation was used, its base being asphalt. The result is that Kent has good roads.

France proposes to run a motor-car reliability trial over a distance of 5,000 kilometers during the early part of the year 1912, the cars to be divided into two classes. Light automobiles to include all machines, of which the price of chassis without tires shall not exceed $1,600; and voiturettes, complete, the price not to exceed $800. It will be stipulated that competing cars shall be equipped with two-seated bodies, wings, steps, lamps, headlights and wind-shields. Not more than three machines may be entered by any one manufacturer. Repairs during the luncheon hour will be debarred. The regulation average speed for the light cars will be thirty kilometers per hour; and twenty-five kilometers is set for the pace of the voiturettes. The fees for entry are 500 francs for one car; 900 francs for two cars, and 1,200 francs for three cars entered by the same manufacturer; 250 francs for one voiturette; 450 francs for two voiturettes, and 600 francs for three voiturettes entered by the same manufacturer. The route, starting at Paris, is to comprise Besançon, Lyons, Grenoble, Nice, Marseilles, Montpelier, Toulouse, Bordeaux, Nantes, Le Mans, Rouen, Lille, Rheims, and return to Paris.

The London fire brigade has at last dispensed with solid tires used on runabouts or tenders, substituting pneumatic tires in their place.

A recent experiment in road-paving near Birmingham, England, has proven a success in many ways. It is called the new "leather pavement." The base of the composition is waste shreaded leather, reduced almost to a pulp. This is whipped into a batter with tar and bitumen, after which it is spread on a concrete road-bed. After it has become dry this new "leather pavement" settles down as hard as a rock and affords a smooth, cushion-like surface. The heaviest of motor-car wheels make no impression on it. Dust does not result from the traffic, nor does the road get greasy. It is weather-proof, noiseless, and a boon to the foot of the horse, as well as to the tire of the motor-car. Its cost has not been determined; but, should it not prove too expensive, it may make a great improvement in modern methods of road-building.

The County Council of Warwickshire, England, has passed a by-law making it obligatory for the occupant or driver of every vehicle, no matter of what type, bicycle, cart, carriage or motor-car, to attach a red light on the rear of the vehicle while passing through or traveling in the county.

The latest invention in the way of covering for automobile footboards is a matting made in picturesque designs from aluminum. One cannot slip on it and its metallic composition makes it easy to clean. It is also almost indestructible.

The automobile will soon be running over a section of the Congo territory which echoes its tales of barbarous deeds of mutilation in connection with the harvesting of rubber by natives. Already the motor-trolley has leapt out across portions of the land, the line threading dense forests. Preparations are on foot for the making of roads for automobiling, the contemplated scheme being to link up Broken Hill, Bwana Mkubwa and Luembe.

Odd as it may seem, motor-bus and tram-car drivers of gay Paris have been up to the present time allowed to smoke while driving their respective vehicles through the streets of the French capital. But the custom developed into such a nuisance that the public raised its voice in protest; in consequence of which the companies have issued orders to the men forbidding them to smoke during the hours they are on duty.

The Royal Swedish Automobile Club has revised the rules which governed the Gothenburg-to-Stockholm motor-car trial last winter, under which 48 and 60 hours respectively was the maximum time for the two classes. Under the new rules the minimum speed allowed will be 10 and 9 kilometers respectively per hour. Should the course exceed 600 kilometers the permissible speed will not include compulsory stops.

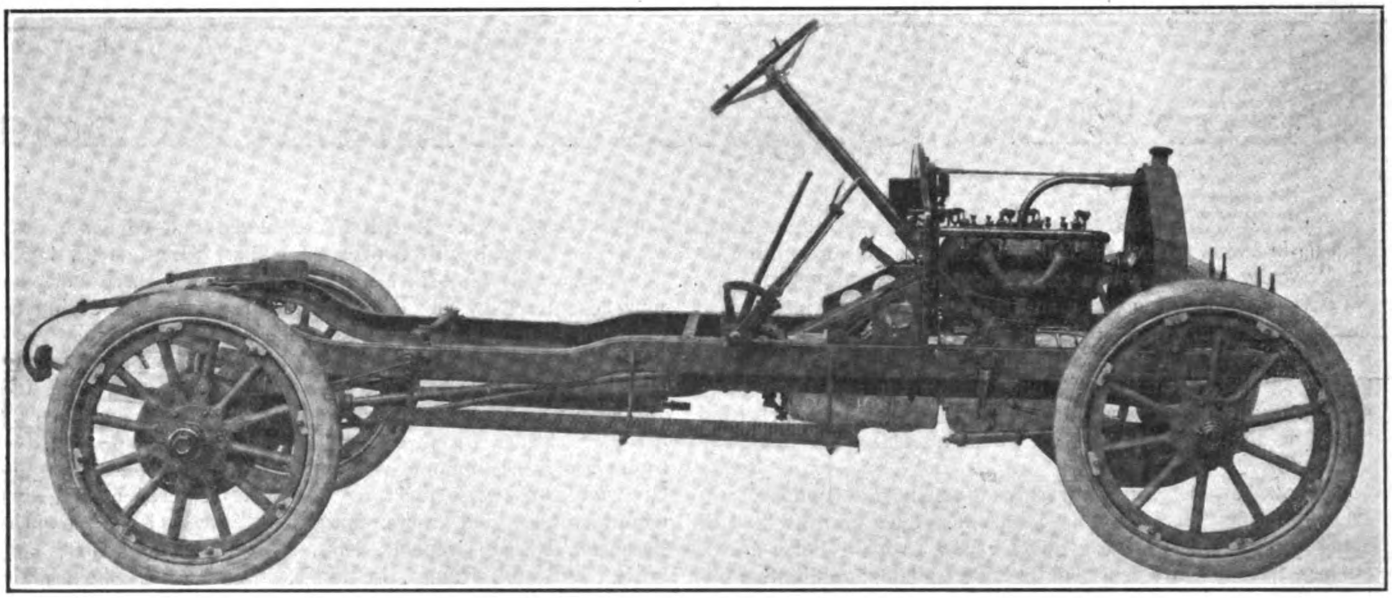

Fig. 1—View of chassis of the Bergdoll 30 for 1912, showing double drop construction

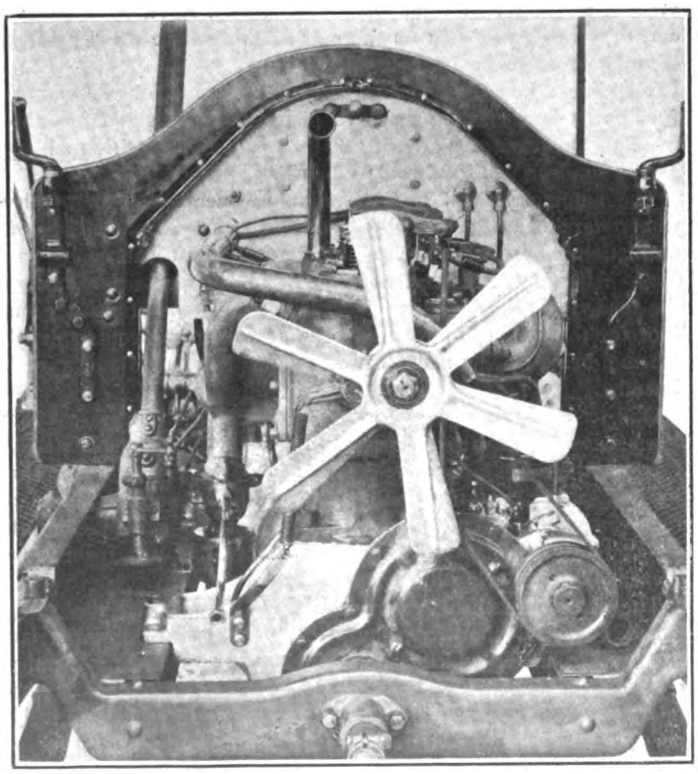
Bergdoll Adds a Forty to Its Line

RADICAL departures from the usual practice have not been made by the Louis J. Bergdoll Motor Company, of Philadelphia, Pa., in bringing out its line of cars for the season of 1912. The company is continuing to build the Bergdoll 30, which first characterized its line last year, but in addition to that a new and larger car has been added. This car is equipped with a motor claimed by the makers to develop slightly in excess of 40 horsepower.

The motor of the latter has a bore of 4 inches and a stroke of 6 inches, giving a stroke-bore ratio of 1.5, and has four cylinders which are cast en bloc. The exhaust valves are located on the side of the cylinders and are placed just below the removable caps, so that they are readily accessible in case it becomes necessary to withdraw them. The water jackets are cast integrally with the cylinders and extend around the valve ports, thus adequately cooling these parts. The inlet valve opens downward into the head of the cylinder, while the exhaust valve opens upward. The inlet valve cage is readily removable so that this part is also easy to reach should it become necessary to remove the valve for purposes of inspection or repair. A noteworthy feature of the valves is that the inlet valve is provided with a flat seat while the exhaust valve seat is of the 45-degree type. In case it is desired to fit a duplicate set of spark plugs there is an aperature in the top of the cylinder sealed by a plug.



Front view of motor and dash of Bergdoll 30

The flat head pistons on the new motor are 5 inches in length and are fitted with four piston rings located above the wristpin and ground to fit. The material of the piston is of selected gray iron, ground to a finish and balanced in connection with the other reciprocating parts of the engine. The wristpins are of hardened steel and are hollow in section. They are 1 1/8 inch in diameter and the thickness of the metal is 3/8 inch. The upper ends of the connecting-rods are fastened to the wristpins by means of clamp bolts held by the bolts which pass through them. The connecting-rods are 12 inches in length and are drop forgings of selected steel. They are of I-beam section and at the lower ends are broadened to secure a bearing surface of good length on the crankpin.

The crankshaft is carried upon three main bearings of annular ball type, the rear end connecting to the flywheel member of the clutch, while at the forward end the shaft terminates in a gear which drives the half-time wheels. The crankshaft is of carbon steel drop forged and ground to fit. The crankpins are 2 1-8 inches in diameter and the connecting rods are bushed with die-cast metal to form a bearing surface for them. The connecting-rod bearing caps are of adequate size to guard against breakage at this important point.

The camshaft is readily accessible beneath a cover plate in the side of the crankcase. When this plate is removed the whole valve mechanism may be inspected and the camshaft bearing cages removed. The cams are an integral part of the camshaft and act directly upon the tappet rods and not through fingers. The camshaft is carried upon three annular ball bearings which are of large size in order to reduce wear on these parts; it is driven through a set of gears at the front end of the motor. These gears are encased in a housing, the cover of which is made removable by taking out the stud bolts which hold it in place. The last wheel in the train is used to drive the water pump and magneto shaft, while the middle wheel drives the camshaft. An Oldham coupling is inserted in the latter shaft, which is an exterior fitting, so that it may be readily taken down when such an act is necessary. The valve action is readily adjustable by means of the two nuts which may be seen in Figs. 2 and 4. The wear on the tappet rods it taken up by merely turning these so that the lost motion disappears. The valve springs are also exterior fittings and are thus readily accessible.

The crankcase is an aluminum casting and is extended back in order to make a housing for the flywheel. The motor supports are four in number.and are cast integrally with the crankcase, the rear two being on either side of the clutch housing. A shelf is cast on the side of the crankcase to support the magneto The crankcase is in two parts, the lower being a factor in the oiling system, which will be described later. The upper part forms a basis of support of the cylinder casting as well as of the bridges which carry the bearings of the crankshaft and camshaft.

The motor is lubricated by the splash system. The crankcase is divided into four splash troughs into which the connecting-rods dip. Besides being divided laterally to form the splash chamber the crankcase is also divided horizontally in such a way that the casting has a double bottom. The upper bottom is molded in such a way as to form the splash troughs just described. Below the troughs in what may be called the lower bottom of the crankcase the oil is carried in a plain basin-shaped reservoir.

The reservoir in the bottom of the aluminum crankcase casting is filled through the breather pipe. In filling, the cover of the breather is removed, disclosing the filler opening equipped

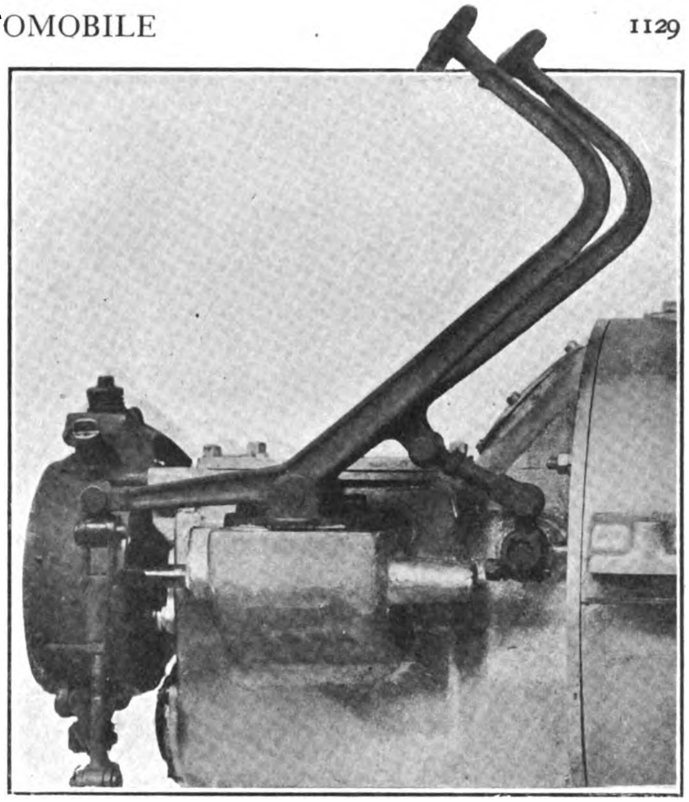


Fig. 3—Showing the unit housing of the clutch and control pedals

with a strainer. The upper test-cock on the side of the crankcase is left open while filling and oil is poured into the filler hole until it starts to flow from the cock. The cock is then closed tightly. The lower test-cock is for the purpose of draining the reservoir, the oil never being allowed to become so low that there will not be a flow from this cock. The breather pipe is located on the exhaust side of the motor, just behind the magneto shaft. The oil is drawn from the reservoir by a pump which

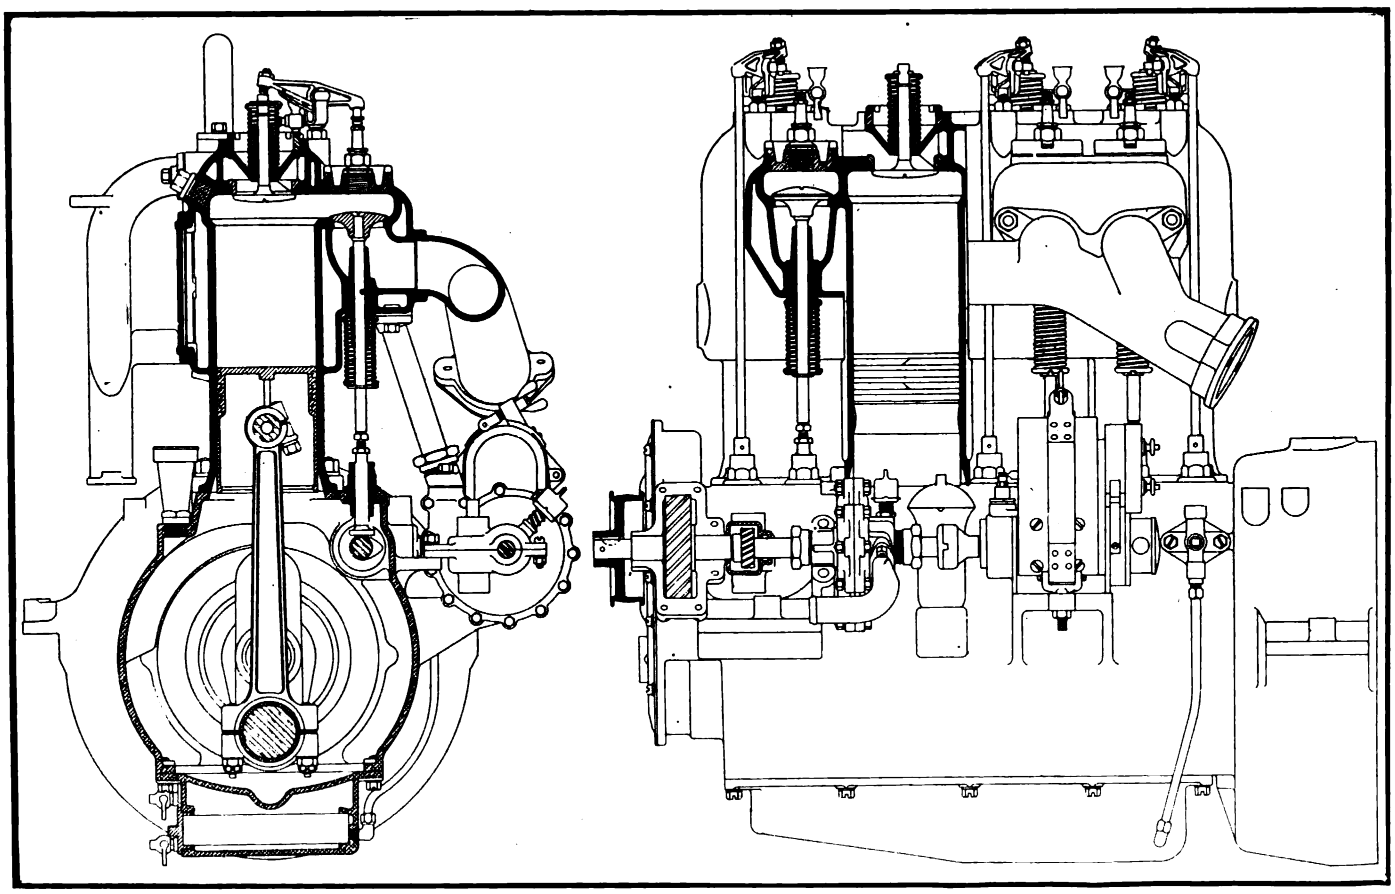

Fig. 4—Transverse section and part longitudinal section through the Bergdoll motor

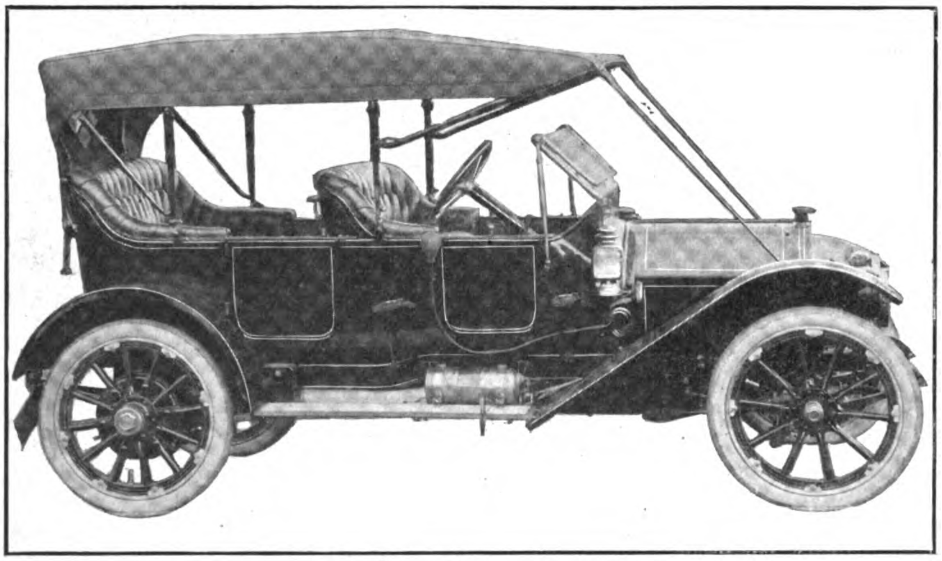

Fig. 5—Illustrating the Bergdoll torpedo touring car

takes the oil from a suction pipe leading to the pump from the rear end of the exhaust side of the motor. The oil is then forced up through a vertical lead into the sight-feed located on the dash. Thence the oil flows down onto the opposite side of the motor and is led into the crankcase at the forward end. The oil from this lead will fill the front splash trough and then overflow into the second and from there to the third and so on to the rear. After reaching the correct level in the rear splash trough the oil overflows back into the reservoir through an overflow in the rear of the crankcase.

Ignition is effected by a Bosch magneto known as the easy-starting type. With this magneto no batteries are required, and hence none are fitted on the Bergdoll cars. The magneto is readily dismounted from its position on the side of the crankcase by unscrewing the bolt which holds the clip over the top of the magnets. The bolt is mounted on a joint so that when the nut is loosened the bolt may be swung downward and the magneto lifted from its shelf.

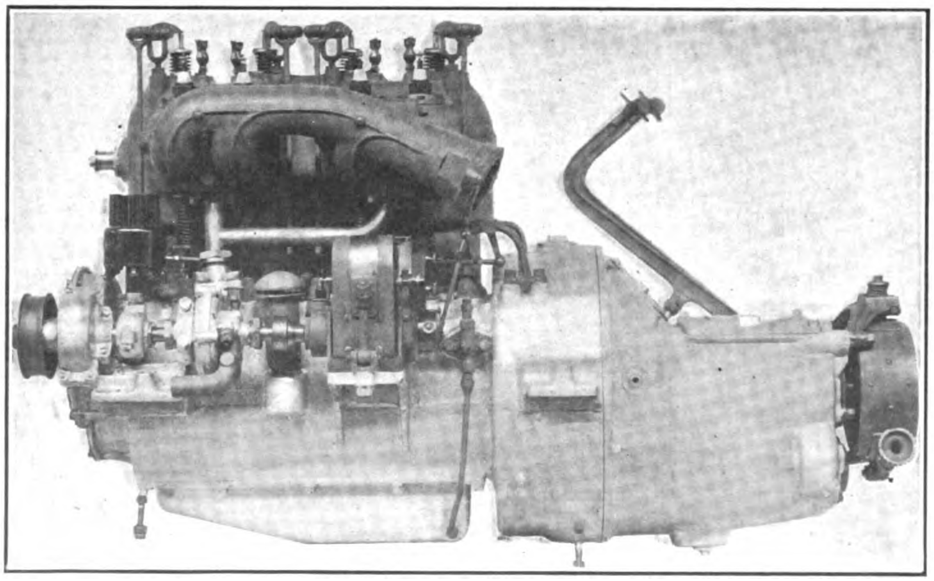
The carbureter is of the automatic float-feed type. It is mounted on the right side of the motor and supported by a broad flange at the bottom of the Y-shaped intake manifold. Two bolts pass through this flange and a gasket is inserted to prevent leakage of the mixture at this point. The throttle is controlled from the driver's seat by a lever on the steering column in the usual manner. Adjustments may be made on the carbureter by means of knurled screws which are fitted in an exterior position and govern the gasoline, air and automatic air intake. In order that the mixture be kept constant at all times the carbureter is hot-water-jacketed, the supply being drawn from the lower part of the water-jacketing of the cylinders on the right side.

The clutch is of the multiple disk type faced with asbestos fabric known as thermoid. It is encased in an aluminum housing which is a continuation of the crankcase as explained above. The rear part of the housing is formed by the casing of the gearset, which is so shaped that it fits against the rear of the flywheel casing and is held thereto by means of bolts. An inspection cover is fitted in the clutch housing, through which any necessary adjustments may be made, as it is large enough to permit the hand to easily pass into the interior and manipulate any of the parts requiring regulation. The necessity for adjustments on this type of clutch, however, is negligible, being for the most part due to carelessness. The majority will be found to be cases where the operator of the car has neglected to give the clutch the ordinary care.

The drive is taken up from the clutch through a gearset of four forward speeds and one reverse. The drive and gear change shaft are of chrome vanadium steel, while the gears are all of nickel steel, a combination which should give great durability and strength against sudden stresses. The bearings which support the shafts are of the ball type and so designed as to withstand end thrusts when changes in speed are made and when the clutch is engaged and disengaged. The gearset is rendered readily accessible by raising the floor boards of the car, disclosing a flat cover plate which fits over the gearset. There are four bolts holding this plate in place and a gasket is inserted in the joint to make it oil-tight.

At the rear of the gearset there is a universal joint which separates the change-speed mechanism from the drive shaft through which the power is transmitted to the rear axle. This universal joint is for the purpose of taking up any changes in alignment which occur owing to the different degrees to which the car is loaded. A difference of one person in the load of the tonneau will change the slope of the shaft and hence alter the direction of the drive. This universal joint takes up this difference and renders it possible to operate the vehicle under all conditions of load. The drive shaft is of chrome vanadium steel and is fitted at the rear end with a universal joint through which the power is transmitted to the rear axle. The drive shaft is relieved of all torsional strains by torque rods which connect the rear axle and the chassis frame. The strains encountered when making a sharp turn are thus taken up by other members of the mechanism than the motor and drive, and hence will do no harm to these parts. The torque rods may be seen in Fig. 1, which depicts the chassis of the Bergdoll No. 30. The arrangement of the drive and the rods is the same on the two models.

The rear member of the universal joint on the after end of the propeller shaft is a part of the short shaft which passes through a stuffing box and into the differential housing on the rear axle.



A complete view of the motor, showing the unit power plant

At the rear of this short shaft, and also an integral part of the same, the bevel pinion which operates the large bevel wheel of the train of differential gears is found. Just within the stuffing box through which the short shaft passes there is a seating which holds an annual ball bearing. This in turn supports the shaft. Another ball bearing is located just forward of the star pinion and supports the rear end of this shaft as well as acting as a bearing for the star pinion. The large differential wheel is also carried upon ball bearings of annular type, and drives the differential wheels which in turn actuate the live axle shafts.

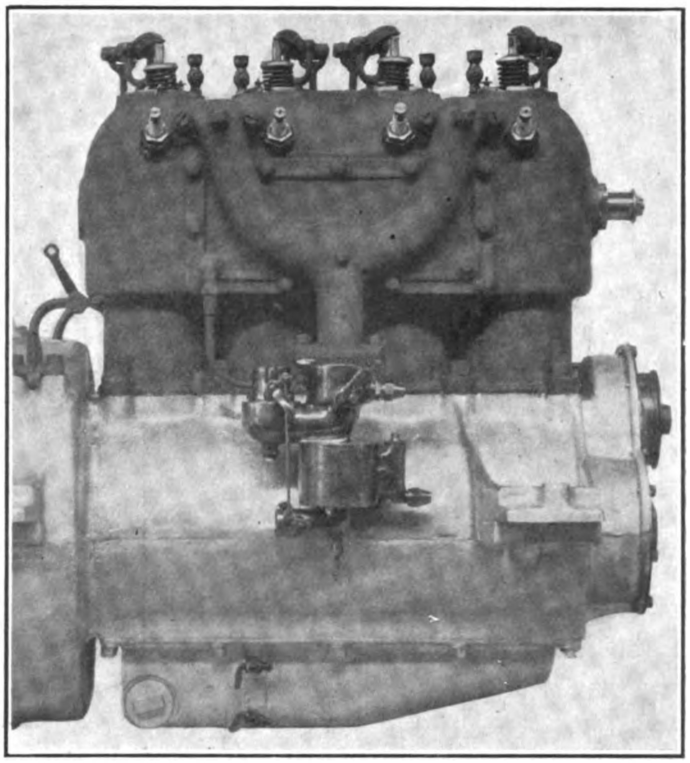
The rear axle is of the floating type, the housing being of pressed steel. The live members are all carried upon annular ball bearings and the material of which they are made is heat-treated nickel steel. The ends of the axle shafts are squared so that they may be readily withdrawn by simply removing the hub caps. When these are removed the ends of the shafts are disclosed and there is nothing else required but to simply draw them out. There is a flange on the end of the shaft to which the wheels are bolted. Six bolts form the means of connection between the wheels and the corresponding holding flange.

The brake drums are a part of the rear wheels. There are two complete and independent sets of brakes for service and emergency purposes. The service brakes are controlled by a pedal and are fitted with equalizers so that the pressure exerted on the drums on both sides of the vehicle is the same. These brakes are of the external type, consisting of bands which contract about the drums on the application of pressure on the pedal. The bands are faced with thermoid, while the drums upon which they act are of steel. The drums are 14 inches in diameter and 2½ inches in width, giving ample surface to bring the car to rest smoothly and rapidly. The emergency brakes, which are controlled by a lever, are of the internal expanding type. Upon application two internal bands are spread apart, turning about a pivot and bearing against the interior of the drum. The power is equalized on these two brakes in the same manner as in the other brakes; that is, through equalizing rods.

The wheels are of the Schwartz artillery type, the wood used in their construction being of second-growth hickory. The rear wheels are of slightly heavier construction than the forward pair, having twelve spokes while the forward wheels have but ten. The wheels are 36 inches in diameter all around.

A glance at the chassis of the 30, which is shown in Fig. 1, will give a general idea of the frame construction. The side members of the frame are of channel section and of dropped construction, being raised up over the rear axle. The material used throughout the frame is pressed steel and the various members and sub-members are hot riveted to each other. Two flanged triangular gusset plates are riveted to the side chambers and to the dash structure so that great stiffness in this part of the frame is attained. The motor is supported by a sub-frame of deep construction which is riveted to the main members of the frame.

The front axle is a single drop forging of selected steel and is fitted with large size annular ball bearings for carrying the front wheels. The steering gear is of the worm and gear type, and is controlled by an 18-inch hand wheel mounted on a five-armed aluminum spider. The spark and throttle control levers and quadrants are mounted upon the handwheel in the usual manner. The control is on the left side of the car throughout, and in the case of the fore-door models the levers are contained within the body. A self-starter of the Ever-Ready type is included on the 40 if so specified by the customer, without extra charge. The starter is designed to be of use in starting the motor at any time, whether it be stalled or in starting for the run. It is guaranteed to start the same by a simple pressure on a pedal or lever which releases the brakes holding the mechanism and automatically cranks the motor.



Inlet side of the motor, showing carbureter and intake manifold

The chassis is supported in the front upon semi-elliptic springs having a span of 39 inches and a width of 2 inches. The rear springs are 45 inches long and 2 inches wide, being ¾-elliptic in shape. The spring shackles are fitted with integral grease cups while the lubrication of the springs themselves may be accomplished by jacking up the car and applying the lubricant after the weight has been lifted from the spring.

This, however, will not have to be done very often as it comes in the category of overhauling. The springs are so shaped that the lubricant will be held in place for a considerable length of time without replacing.

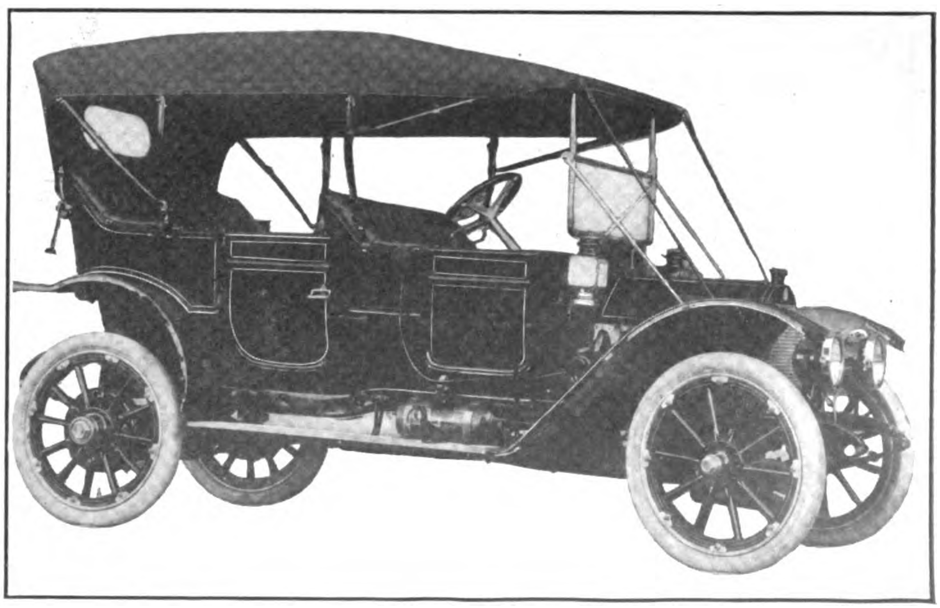


Fig. 8—A view of the model C touring car of 1912 type

Fluid Pressure Speed-Changing

CONSIDERABLE danger to transmission gears is involved in the possibility of changing and consequently stripping the gears while in mesh. On the other hand, even if speed-changing is done in the correct manner, with the clutch disengaged and the gears at momentary rest, the work of shifting the gears is not such an easy one as might be desired. These two setbacks of transmission gears are claimed to have been overcome in the construction of a speed-changing device by Allen M. Irish, of Bath, Me. The device consists principally in a balanced plug-cock which serves to regulate the flow of gas under pressure to the mechanism's working clutch and transmission gearset.

The general arrangement of the device installed is seen in Fig. 1, where P is the cylinder of the engine, or, still better, that of a mechanically operated air pump, charging air through check valve V into storage tank S, where it is compressed to the proper degree. A tube leads from S to the distributing valve V_1, which is regulated through a shaft and gear attached at the top of the steering post right beneath the wheel. Fig. 2 is explanatory of the construction of the valve V_1, Fig. 1, which was first referred to as a balanced plug-cock. Valve plug P, Fig. 2, is fitted into the valve body B, with passageways bored in it, permitting of the passage of a gas from inlet I to port T or higher up around the valve spindle S to the cylindrical space S_2. This space is sealed upwardly by means of the valve V_1 which is held against the seat by spring S_1. Tightness of the valve V_1 against its seat is insured through gasket G. The rod R serves to depress V_1 at the will of the operator, in which case the passage of the gas is continued the clutch supply port C_1. C C are clutch exhaust ports, the function of which will be explained later on. The rod R is operated by operating lever O fulcrumed to it at F and pivoted at P_1.

If the valve is in the position Fig. 2, the flow of the gases from the storage tank is illustrated by the horizontal section through the plane of T. Port T here registers with lead T_2 through which the gas is directed to the gear-shifting mechanism G_1, Fig. 1. When T and T_2 registers as here illustrated, the operating lever O rests in a notch N_1, Fig. 4, so that the valve plug is held in its position.

Lifting the operating lever as seen in Fig. 5 permits of rotating it until it comes to rest in notch N, Fig. 4. While the lever is out of engagement with either notch, T bears against the valve body B and valve V_1 is depressed off its seat, and the gas entering at I and passing in part by the port T_2 flows up around the spindle, leading through the clutch supply port C_1 to the clutch-operating cylinder, Fig. 6. The cylinder C is supported by frame F and closed at its other end by the cylinder cap C_1. Plunger P is adapted to rotate in the cylinder, the piston rod is resting in the plunger hollow H, while the spring S serves to hold piston rod and plunger in constant engagement. Gaskets G and G_1 are provided as a double insurance against any gas leaking from the space containing the spring past the piston and out of the upper end of the cylinder. The gas coming from the distributing valve enters the mechanism at E and drives up the piston and plunger rod. The latter is fulcrumed to the clutch lever C_2 as shown, and this lever being pivoted at a place some distance from the fulcrum disengages the clutch. In lifting the rod R the action of a spring holding C_2 to the engaged position must be overcome, and as soon as the pressure driving up the piston P ceases to act, the piston returns to the position indicated by the dot-and-dash line and the clutch again drops into engagement.

This takes place after the operating lever O has completed its travel from notch N_1 to notch N and has come to rest in the latter. At the same time valve V_1 is lifted back to its seat, Fig.

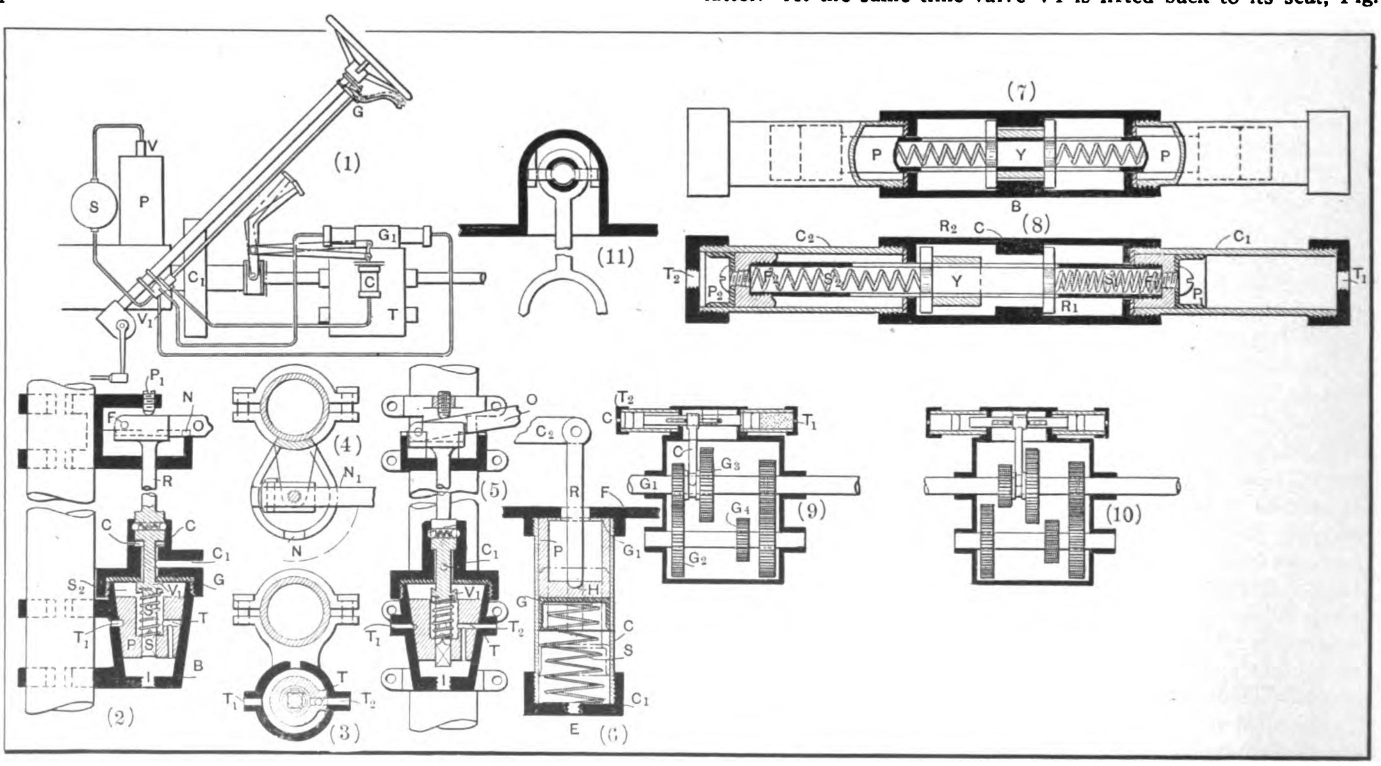

Fig. 1—General arrangement of Irish gear. Fig. 2—Method of attaching distributing valve to steering post. Fig. 3—Section through valve and post. Fig. 4—Operating lever and notches. Fig. 5—Lifting lever for shifting the gears. Fig. 6—Clutch operating mechanism. Fig. 7—Gear operating mechanism when gears are in normal. Fig. 8—Shifting gears by admission of gas through T. Fig. 9—How mechanism operates transmission gears. Fig. 10—Gears in neutral

2, and the gas contained in the gas lead to the clutch-operating mechanism is permitted to escape through C C in the same illustration. When O rests in N, port T registers with T1, so that the gas entering the valve body at I takes a different path.

The gas flowing through T2 and T1 flows to the gear-shifting mechanism, Figs. 7 and 8. The body of this mechanism contains a plunger P P, having attached to its ends pistons P1 and P2, which slide in cylinders C1 and C2. The middle portion of the plunger carries a yoke Y, while inside the plunger springs are fixed at respective ends F1 and F2 of the plunger. Spring retainers R1 and R2 by bearings against the portion C of the body limit the travel of the piston to either side, and tightness of all joints is insured by means of gaskets. Gas may be admitted to the spaces adjacent the pistons through ports T1 and T2 communicating with the outlets of the distributing valve marked in the same manner. The admission of gas has the effect of putting the spring on the admission side under additional compression, while the other spring remains undisturbed.

The operation of the speed-changing device is seen in Fig. 9. By admitting gas through port T1 the piston is moved toward port T2. The yoke is thereby moved in the same direction, bringing gears G1 and G2 into engagement. The opposite movement of the plunger and yoke, caused by admitting gas through T2, would bring G3 and G4 into engagement. Gears are in neutral, Fig. 10, when the yoke occupies a central position, which is the case when no gas is admitted from the distributing valve if the port T bears against the wall of the valve body. Fig. 11 is a vertical cross-section through the speed-changing mechanism at the point of the yoke, illustrating the manner in which the latter is fixed to the body of the mechanism by keys sliding in guides.

The illustrations bring out a number of details which were not specially mentioned in this description, but which will readily be noted by the man interested in this new construction. Apparently there is little or no difficulty involved in this device, and the only point demanding special care on the part of the maker would be tightness against air or gas under pressure, which can be obtained without too much trouble by exact fitting of the parts and sufficient packing of the joints by gaskets. No stuffing-glands are used throughout this apparatus. One of the refinements of the system is a shut-off valve interposed in the line between pressure tank and distributing valve, the shut-off being operated in connection with a lock, the key of which is in the owner's possession. This arrangement makes gear-shifting impossible when the car is left alone, but a positive locking means would be obtained if the operating lever of the device could be locked, by means of a key, when in a position between the two notches, for then it would be absolutely impossible to move the automobile by its own power without the owner's consent.

By the application of the Irish mechanism the clutch pedal on the footboard becomes superfluous, at least so far as this use of it is concerned. But incidentally the elimination of this member would allow the installation of a second brake pedal in its place, for advantageously working the emergency brakes of the car. Such an arrangement would do away with the rather troublesome situation of a motorist becoming unaccustomed to the use of the emergency brake, because this is unhandy as compared to the service brake operated more easily by its pedal. If, however, the emergency brake can be operated by foot, there is no cause for any disinclination on the part of the automobilist to use it when occasion arises. Besides these, there may be other advantages in this construction which its continued application may reveal.

Harking Back a Decade

FROM *The Motor Review,* December 26, 1901:

The H. W. Johns Manufacturing Company, of New York, and the Manville Covering Company, of Milwaukee, have consolidated, the merger to take effect January 1. The name of the new concern will be the H. W. Johns-Manville Company. The company is completing a plant at Milwaukee for the manufacture of carbonate of magnesia and mineral wool.

It is announced that the International Motor Company, capital $2,000,000, will handle the automobile business of the American Bicycle Company. George Pope has been elected president of the motor concern.

The Equipment Motor Company, capital $6,500,000, has been incorporated in New Jersey and will handle the motor branch of the International Power Company. The Electric Storage Battery Company has won its suit to sustain the validity of the Brush patent before Judge Coxe in the United States court. The suit was brought against the National Battery Company.

Essex County, N. J., has struck a responsive chord in the hearts of automobile owners by raising the restrictions that have been laid against the operation of cars in the public parks within the county. All that the motorist now has to do is register and carry a number in rear and on his lamps; keep within the speed limit of 7 miles an hour; come to a stop if horses appear restive; sound no gong except in crossing a street; be ready to show permit to any guard and in case of failure to observe all these rules the permit will be rescinded permanently. The motorists are delighted.

Under the new French law the chauffeur who has part in any accident and then runs away will be subject to a fine of from 16 to 500 francs and imprisonment for from 6 to 60 days.

Foxhall Keene hired a plumber to make some repairs on one of his racers last week. The plumber may be out of the hospital in a few days, his eyesight having been saved by the prompt efforts of physicians. Some hot resin blown out of a tube almost killed the man.

Joseph L. Brayton, of Cleveland, touring with his wife last week almost came to grief near Geneva, N. Y. A bull broke through a fence and charged the Brayton car. Mr. Brayton put on all speed and managed to escape although the bull was a good second for quite a distance.

The Bartholomew Company is preparing to enter the automobile business at Peoria. The company has been engaged in making peanut and coffee roasters and recently determined to go into motor car manufacture.

The price of Oldsmobiles will be increased to $700 on January 1. This will make the second advance in price in 6 months.

The Automobile Club of America is engaged in a plan for affiliating the various American automobile clubs. The A. C. A. proposes to be recognized as the supreme head of automobile sport in America. This phase of the plan has met with some opposition.

Exports for the week, including both cars and parts, amount to more than $46,000 from the port of New York.

The development of the motor vehicle has been so rapid that the sport, to which no better name than the most awkward one of automobiling has been given, is hardly yet in the club stage. —*Edito ial.*

Henri Fournier, race driver, is quoted in *Success* of January as follows: "I look to see all the ordinary work of transportation in the great cities of the world done without horses. Everything will be done with more speed so as to relieve congestion, but the most important item about the coming of the motor is its cleanliness."

Digest of the Leading Foreign Papers

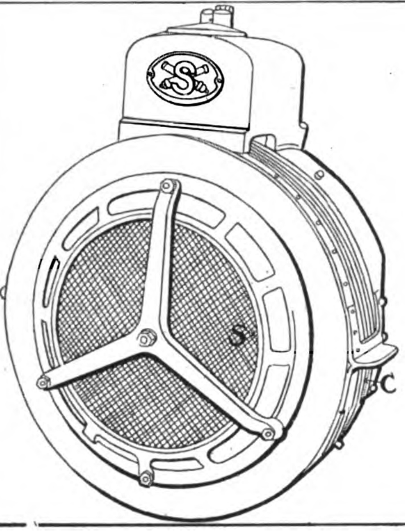

Fig. 1—General view of Solex radiator equipped with centrifugal blower

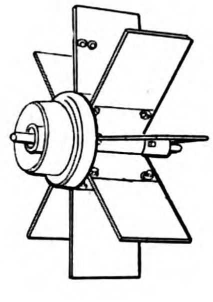

Fig. 2—The centrifugal fan.

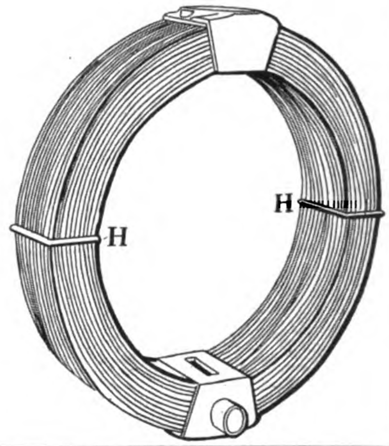

Fig. 3—Nest of smooth copper tubes in forced draft radiator adopted for all Paris omnibuses

Forced-Draft Radiator

THE principle of the centrifugal blower which has been applied for several years in the United States in connection with air-cooled motors, such as the Frayer-Miller and the Franklin, has been adopted in connection with water cooling and a special radiator constructed for all the vehicles controlled by the General Omnibus Company, of Paris, after extensive competitive trials. The radiator in question, called the Solex, is the same that has been used for some time on Schneider and De Dion buses and the appearance of which is familiar to Parisians and visitors to Paris. One of the principal objects aimed for in the construction of this radiator is robustness, considering that the honeycomb radiator has been found too frail for withstanding the vibrations to which a radiator is exposed on commercial trucks and buses running on solid tires. The efficiency of the centrifugal blower, which is rated as five to six times higher than that of the ordinary automobile fan, gives the opportunity for combining the desired strength of construction, as well as low cost of production, with a correct and efficient system for regulating the temperature of the cooling water independently of the vehicle speed and somewhat in accordance with the variable heat generation of the motor. The fundamental idea of the designers seems to have been the simple and obvious one that if the positive-acting centrifugal blower is capable of improving the regulation of air-cooled engines, though it is difficult to lead the air currents so that they will absorb heat equally from all those parts of the cylinder surfaces which are in equal need of cooling, it should be doubly advantageous in connection with a radiator, if the latter is specially built with a view to giving the air currents unhindered passage over the surfaces to be cooled, at all motor and fan speeds. In the ordinary radiator, with a thrust or suction fan placed behind it, the resistance to the passage of the air over the water conduits is increased very much at high fan speeds through the formation of eddies due partly to the tubular shape of the air channels and partly to the irregular relations between the air currents and the air passages. The accompanying illustrations show the simple mechanical arrangement sin the new radiator design by which these shortcomings in ordinary cooling methods have been avoided.

The ventilating fan, Fig. 2, is placed in the interior of a nest of copper tubes, Fig. 3, two bundles, H and H$_1$, of these tubes being bent in half circles and gathered into a collector B for the hot water at the top and another collector C for the cooled water at the bottom. The centrifugal fan F draws the air in through the opening around its axis and throws it out around the whole periphery, and in between the smooth copper tubes which are suitably spaced apart to allow the air to pass. The central air intake is protected by a screen S, Fig. 1, to reduce the quantity of gross impurities which a centrifugal fan is liable to draw from the atmosphere, and it is noticed that the arrangement of the tubes, in conjunction with their smooth surfaces, renders it easy to clean the cooling surfaces of whatever foreign substances may find lodgment there. The curved conformation of the tubes allows them to yield under the influence of vibrations or flexions of the chassis without straining the joints with the bronze collectors. The whole nest of tubes is protected against injury from the outside by means of a sheet metal casing, being secured to this casing by two bolts which pass through tubular channels in the collectors, still leaving the nest of tubes free to accept deformations, and the casing is mounted upon the chassis by suitable steel brackets. At the center of the casing a shaft is supported in front by means of an aluminum spider and at the rear in a steel bracket, and upon this shaft the fan revolves mounted upon two ball bearings more than 10 inches apart.

On top of the upper collector B there is mounted an aluminum tank T holding about 2 gallons of water, for a motor of about 30 horsepower, but the hot water from the cylinders is discharged into the collector. The author of the article mentions that this forced draft radiator was in use upon the Lefebvre tractor at the recent trials of self-propelled agricultural machines at Roubaix and Laon and proved to be the only one providing sufficient cooling for the hard-worked engines on those occasions.—*La Vie Automobile.*

Oxy-Gasoline Flame for Welding and Soldering.—According to a somewhat indefinite report, gasoline, benzol, kerosene or alcohol may handily be used in the place of acetylene gas for autogenous welding or for soft soldering. To this end, the oxygen generator is simply connected by pipe or hose with a tank containing one of the fluids mentioned, and from it the gas mixture is piped under pressure to the burner, where, the report says, it is heated by means of a small lamp. The flame is rather large, it is admitted, but the purity of the gas excludes all clogging of the nozzle, while the fuel is more universally obtained than acetylene or hydrogen and considerably cheaper.—From *Metall-Technik,* October 7.

[The flame, however, is not nearly hot enough to produce a quick, and therefore a good and clean, welding or metal-cutting job.—Ed.]

Uninflammable Imitation Celluloid

Among patented chemical inventions, Leon Labbé registers several related methods for producing imitation celluloid which is not inflammable and whose use in automobiles—for windows, fittings, body panels and perhaps elastic tires—might be found worth considering, the fire risk of real celluloid being eliminated.

The base of the substance is gelatine or casein or both, to which is added lac or jellied silica, to increase the strength and reduce the water-absorbing, hygronomic properties of the base. Three methods are specified, numbered in the following 1, 2 and 3.

(1) A solution A of gelatine is prepared by heating 25 grammes of gelatine with 100 grammes of water to 65 degrees centigrade in a wet-bath. To this are added 5 grammes of acetic acid and thereafter 2 grammes of alunite. This mass is cooled preferably by artificial refrigeration, is wrapped in cheese cloth and squeezed, thereby passing through the meshes of the fabric in form of threads, which are received in a basin of water. It is then heated to 65 degrees centigrade, and 2 grammes of glycerine and 2 grammes of glucose are added. This compound is filtered. Then a solution B of lac is prepared. It can be made with alcohol, using 50 cubic centimeters of 90 degrees alcohol for 10 grammes of lac. Or it can be made with ammonia in the same proportions. It can also be made with water in the same proportions, but then some borax must be added, and the water with the borax must be preheated, whereafter the lac is added, and the whole is brought to the boiling point and filtered. The solutions A and B are now mixed, and the result, after evaporation or drying, is an imitation celluloid of fine quality and transparency.

(2) The solutions A and B are prepared as under 1. A third solution C is made of casein by adding 10 grammes of borax to 100 cubic centimeters of water, heating it, adding the casein, heating now to the boiling point and filtering. The solutions A, B and C are then mixed, and, after evaporation and drying, the compound is suitable for articles which need not be wholly transparent.

In evaporating and drying the following is observed. The mixtures of A and B and also that of A, B and C are allowed to evaporate until they reach a thick sirupy consistency and are then run into molds. When hardened sufficiently to be removed from the mold, the formed article is at once plunged into a bath which renders the albuminoid matter insoluble. This bath may be on a base of formic aldehyde or of alum or acetate of aluminum, or of any equivalent substance capable of producing the desired result at a strength preferably not exceeding 5 per cent. The bath should impregnate the article completely, and the duration of the submersion in it must depend upon the thickness of the material. Thereafter the article is dried completely in a drying room.

(3) This method is based on the property which albuminoid solutions possess, of precipitating solutions of silica in the form of collo-silicates which are insoluble in water, and on the use of silico-glycerine jelly together with these collo-silicates. Silica, besides being cheaper, has the advantages over lac that it gives greater strength and hardness and that it can enter into the composition of the finished product in larger proportions without reducing the transparency.

The proceeding for obtaining the albuminous collo-silicate may be as follows:

Three solutions D, F and G are first prepared; namely:

D, a silicious solution, by adding to a weak solution of alkaline silicate a great excess of hydrochloric acid, which leaves the silicate in solution. If, on the other hand, too little acid is added, the silicate will be precipitated as a jelly.

E, a silico-glycerine jelly; to obtain this, an alkaline silicate is treated with hydrochloric acid, as before, but taking care not to use any more acid than is necessary to precipitate the silica from the solution of alkaline silicate. Thereafter the siliceous jelly obtained is mixed with glycerine and heated to the boiling point.

G, an albuminoid solution, which can be, for example, a solution of gelatine, or may be of casein, or of gelatine and casein mixed. This solution is obtained as mentioned under 1 and 2.

When these three solutions are prepared, the silica solution D is poured little by little into the albuminoid solution G, thereby forming a precipitate of albuminous collo-silicate, which is now neutralized by the addition of ammonia or caustic alkali. This produces a thick jelly in which much water is retained. The water is eliminated, either partly or totally—according to what product is wanted—by treating the jelly with absolute alcohol.

This jelly of albuminous collo-silicate is then mixed and worked (with pestle or equivalent means) into the glycerine jelly F until the mixture is uniform, and the complete insolubility of the compound is secured by treating it in a bath, such as mentioned under method 2.

Drying and compression complete the process, and the flexibility of the product may be varied at will by modifying the proportion of glycerine. A scale of variations in strength and hardness may be established by varying the proportions of alubuminoids and of silica, the latter determining the hardness of the product.

When transparency is not required, casein may be extensively used, reducing the cost of production. Coloring matter, whether the colors are soluble or opaque, should be introduced in the albuminoid solution before the siliceous solution is poured into it.—From *Chimie Industrielle,* November.

Automobile Metallurgy Made Easy

By E. F. Lake

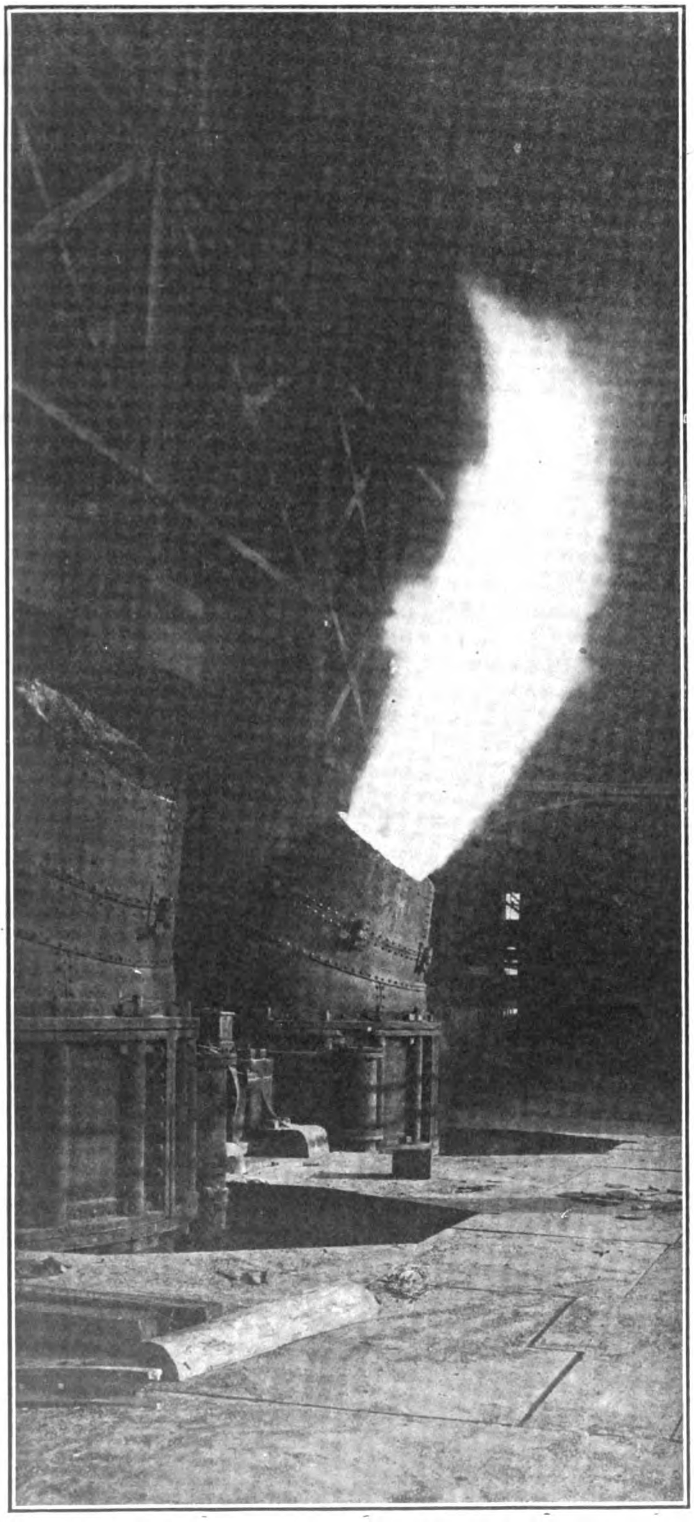

Fig. 1—Bessemer converters during the blow and when the steel has been poured out. On the left can be seen the converter from which the molten steel has been poured while that on the right was "blowing" when the photographer snapped his camera.

Part VI

Bessemer Steel — Its Manufacture, Physical Qualities and Chemical Composition

(Next Week—Open-Hearth Steel)

HUGE quantities of steel are turned out by the Bessemer process; in fact, a much larger tonnage of steel is turned out by the Bessemer process than by all of the other processes with which steel is made. In making steel this way the iron ore is melted in a furnace and what is known as cast iron is taken out of a tap hole at the bottom of the furnace and run into clay-lined ladles on car trucks. These ladle-cars are run to the Bessemer converters, Fig. 1, and the molten metal poured into them. The residue from the iron ore is called slag and being lighter than iron, it floats on the top of the molten metal in the ore furnace. This slag is drawn from the furnace through another tap hole that is located higher up.

The difference between the various iron products is that cast iron usually contains from 3 1-2 to 4 1-2 per cent. of carbon and the others less than this. After the percentage of carbon has passed 0.90 it will not thoroughly dissolve in the iron and separation begins. Above this percentage some of the carbon segregates in the iron in the form of graphite. This separation and formation of graphitic carbon usually becomes quite pronounced when 2 per cent. of carbon has been reached. Divisions are thus usually made on the following basis: Iron products containing over 2 per cent. of carbon are classed as cast iron; those containing between 0.10 and 2.00 per cent. are called steel and those with a carbon content below 0.10 per cent. are called wrought iron. When the carbon is below 0.30 per cent. steel is soft and cannot be hardened enough to prevent its being cut with a file. It is then called machinery, soft or low carbon steel. When the carbon content is between 0.30 and 2.00 per cent. a steel can be hardened enough to enable it to cut other steels. It is then termed half hard, hard, tool or high carbon steel.

Thus the molten cast iron when poured into the Bessemer converters contains a large amount of graphitic carbon which has to be removed to make it into steel. To get this carbon out air is forced through passages opening into the bottom of the Bessemer converter, Fig. 2. The air passing up through the molten metal causes it to boil and oxidize out all of the silicon and manganese and most of the carbon. After these have been burned out of the molten metal enough more is then added to give the finished steel the properties that are desired, this being the easiest way of controlling the amount. When this has been done the converter is tipped over, as shown to the right in Fig. 2, and the steel poured into ingot molds, from which it is taken to be rolled, hammered, pressed or forged into the desired shapes.

This is the simplest process by which steels are made and consequently they are the cheapest steels that are obtainable. Most of the railroad rails and structural steel shapes are made by this process, the cast ingots being taken directly from the converter to soaking pits. In these they are soaked in heat until they arrive at the correct temperature for rolling, when they are rolled into the desired shapes. All kinds and shapes of bar steel, wire, etc., are also made by this process and sold in the open market.

The ordinary carbon steels, with any percentage of silicon, manganese and carbon that is desired, can be made in the Bessemer converters, but impurities such as sulphur and phosphorus cannot be reduced to as low percentages as when other methods are employed in making steel. Then, again, the air passing up through the molten metal causes it to absorb considerable quantities of oxygen, hydrogen and nitrogen, either in the form of occluded gases or in large enough segregations to form blowholes. Steels made by the other processes do not absorb the gases in such large amounts and they are, therefore, denser, tougher, stronger, etc., than those made by the Bessemer process. Thus, while Bessemer steel is the cheapest steel obtainable, it does not have the tensile strength or other mechanical properties that steels do which are made by other processes.

In the manufacture of steel rails titanium has been added to the molten metal as it is poured from the Bessemer converter into a ladle, and it almost entirely removes the occluded or segregated gases mentioned above. It thus adds to the strength and wearing qualities of the metal. Railroad rails, which are subjected to the frictional wear of car wheel flanges as they roll over them, have been made to last four times as long as the ordinary Bessemer steel, and especially when used on sharp curves where this frictional wear is very high. The increase in cost of treating steel in this manner has been made considerably less than $2.00 per ton.

This would indicate that gears, frictional clutches, shafts, brakes and some other automobile parts might have a greater resistance to frictional wear and be tougher if titanium were added to the metal. They might even be made from a titanium-treated Bessemer steel. For such important parts, however, it would be better to use the titanium in steels made by other processes as such injurious elements as phosphorus and sulphur could be reduced to lower percentages. The difference in cost between Bessemer steel and that made by the next best process is but the fraction of a cent per pound on some grades and hence it hardly pays to use it for automobile parts.

Such parts as the brackets that hold the steps to the frame, pedals, change-gear lever, hood retainers and others that do not have any particular strains put upon them can be made from Bessemer steel without weakening the car. Many times such parts are made of brass or bronze for ornamental purposes, and Bessemer steel is much stronger than these. Its price is so much cheaper that it can profitably be used on the cheaper cars. The frame, brake bands, frictional clutch discs and similar parts that require considerable resistance to strains and frictional wear have been made from ordinary Bessemer steel even though they should have been made from a better grade. Many times dishonest dealers sell Bessemer steels for those made by more expensive processes, or they mix Bessemer and open-hearth steels together to enlarge their profit. This, however, is a subject that must be taken care of by the buyers, as it is difficult to tell one from the other.

As a general rule, Bessemer steel should not be used in any part of a motor car, although the titanium-treated Bessemer steels might give good results when used for certain parts, and ordinary Bessemer steel for parts that are not important, when cheapness is a factor.

The high strengths that can be obtained in steels made by other processes cannot be given to those made in the Bessemer converter. Any gases present are bound to lodge between various molecules of the mass and separate them so they cannot cling together. This entirely destroys the cohesive force at that point, and consequently lessens it in the whole mass. It is difficult to obtain Bessemer steels with a tensile strength of 125,000 pounds per square inch or an elastic limit of 100,000 pounds. Another reason for this aside from that given above, is that most Bessemer steels have a low percentage of carbon, the higher carbon steels usually being made by other processes.

Carbon greatly alters the tensile strength of steel when it is properly heat-treated and the impurities reduced to a minimum. As an instance of this it is very difficult to show a tensile strength above 100,000 pounds per square inch with a steel that contains less than 0.20 per cent. of carbon, while the elastic limit of such a steel runs from 60,000 to 80,000 pounds per square inch. Give a steel, however, 0.50 per cent. of carbon, reduce the impurities to a minimum and properly harden it and the tensile strength can be raised to 250,000 pounds per square inch and the elastic limit to 230,000 pounds. Thus, a difference of three-tenths of 1 per cent. of carbon, or less than one-three-hundredths of the mass in which it is placed, will increase the tensile strength 150,000 pounds. or make it 2 1-2 times the strength of the lower carbon steel. This is out of all proportion to its volume and one of the wonders of metallurgy.

Such high strengths, however, are not obtained in Bessemer steels, as the impurities are not removed to the extent that they should be. The ordinary Bessemer steels, such as are produced for structural shapes and railroad rails, have a tensile strength of about 115,000 pounds per square inch and an elastic limit of 80,000 pounds. The addition of titanium to this steel for the manufacture of rails has raised this tensile strength to nearly 125,000 pounds per square inch and the elastic limit to over 95,000 pounds. To expect more strength than this from Bessemer steels is expecting what is rarely obtained.

Honorary Kinks in Aviation Language

The French War Department has decided that hereafter every aeroplane found suitable to represent the French colors in military pursuits shall be known as an *"avion"* and that the first special weapon to be devised and found of signal value for use from *"avions"* shall be termed an *"ader,"* both terms being accepted as common nouns. These new names are in honor of Clément Ader, whose book *L'Aviation Militaire,* though written long before the triumph of the Wrights, reads like a prophecy, and whose aeroplane, actually built and tried at the same date and which was called *L'Avion* by its maker, would have flown if the science of motor building had been more advanced.

Following upon the official authorization of the new term *"avion,"* it is at once proposed in *L'Auto* to adopt *"avier"* as the verb meaning "to fly" instead of *"voler"* whose double meaning, "to steal" as well as "to fly," is inconvenient. The conjugation of *"avier"* would bring about some new linguistic collisions, however. *"J'avie"* does not sound good for "I fly" and *"nous avions"* for "we fly" caroms with *"nous avions,"* "we had." Probably *"avier"* will have to be turned into an irregular verb, as irregular in its form as in its connotation.

Letters Answered and Discussed

Brake Adjustment

EDITOR THE AUTOMOBILE:

[2,967]—The brake on my car will not hold very well when I apply it and I have to use the emergency brake continually. There is no turnbuckle on the car, but instead a sort of half turnbuckle which connects to the arm as in Fig. 1. How may I adjust the brake?

Pittsburgh, Pa. HARRY BINKS.

If you will take off the fitting you term a half turnbuckle and insert a screwdriver

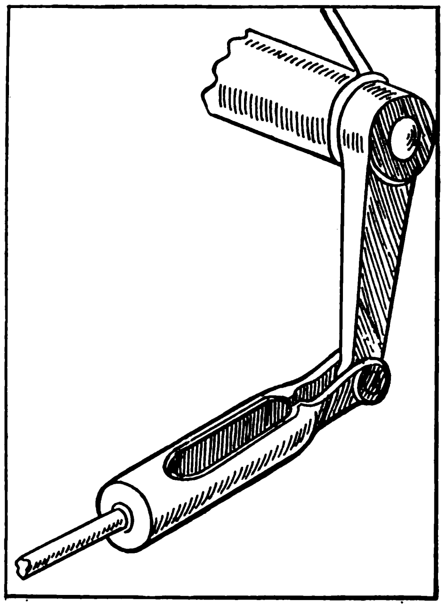

Fig. 1—Brake adjustment fitting in use which is not accessible

as shown in Fig. 4 you will be able to turn it over and tighten up on the adjustment. While at the work it may be well to have a fitting such as is shown in Fig. 2 installed by a repairman who possibly will have sufficient spare parts on hand to put in place. This is a much more accessible means of making the adjustment, the other being antiquated.

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

Both Are Harmless

Editor THE AUTOMOBILE:

[2,968]—Will you please give me your opinion on the following through the pages of THE AUTOMOBILE:

(1) I am the owner of a four-cycle four-cylinder touring car equipped with a dual ignition system consisting of a dry battery set and Splitdorf magneto. The motor has one set of spark plugs. For the past month the dry battery set has been dead and I have been running entirely on the magneto. Will this cause any undue strain on the motor or ignition system? I have no trouble in starting as the motor generally starts on the first turn and never kicks back.

(2) In order to prevent freezing over night I always draw the water from the radiator when I put the car in the garage and while the water is still hot. At the same time I let the steam out of the radiator by removing the cap from the top. Is this likely to harm the motor?

Spokane, Wash. INQUIRER.

(1) This will not harm your motor in the least. Care should be exercised, however, that you do not unexpectedly get a kick back.

(2) This will not harm the motor.

Wants Tire Facts

Editor THE AUTOMOBILE:

[2,969]—I think a matter of interest to car owners would be a few comments and figures on the use of larger size tires than are the regular equipment on some stock cars. For instance, one car advertised to weigh 2250 pounds was fitted with 32 x 3½ inch tires and really weighed 2450 pounds. The tires supplied called for a pressure of 80 pounds. Almost all other tires of the same size call for a pressure of only 70 pounds. Are the above tires sufficient to carry a loaded 5-passenger car? Would an actual saving in tire expense result if 33 x 4 inch tires were used at an additional cost of approximately $15 per tire? Does a smaller diameter tire on a front wheel cut easier than a larger size.

Pittsfield, N. H. WILLIAM B. ELY.

A 3½ inch tire should never carry more than 600 pounds. In a car weighing 2450 pounds, with the addition of five passengers, each weighing 150 pounds, each tire would be called on to bear a weight of about 800 pounds. The tire you speak of would hence be greatly overloaded With the 33 x 4 inch tire the load would still be too great and the car would be undertired. The correct tire to use in this case would be a 34 x 4½. A smaller tire would be apt to be cut more rapidly than a larger one.

Qui Sait ?

Editor THE AUTOMOBILE:

[2,970]—The announcement of H. E. Coffin's address before the English Engineers brings to my recollection the remarks of an English correspondent of *Auto-Car*, London. This gentleman, in writing the account of the last Madison Square Garden Auto Show, has the following to say, as published in *Auto-Car* January 28, 1911, over the initial "N:"

"My impression is that cleanness of design is not a characteristic of American cars. Only two manufacturers showed cars which left nothing to be desired in this respect."

These remarks are particularly timely in connection with Mr. Coffin's address on clean chassis design.

You may publish this, if you wish, but my chief object is to ascertain the names of the two manufacturers referred to.

CHRISTOPHER LIPPS.

Baltimore, Md.

Tips from a Repairman

Editor THE AUTOMOBILE:

[2,971]—Gentlemen: In the number of December 7 I read the inquiries from the following subscribers, and having had quite a good deal of experience as repairman, etc., I would add this to your answers, if you care to publish them:

[2939]—M. E. Long.—The trouble you speak of can be remedied by gas bags, at a

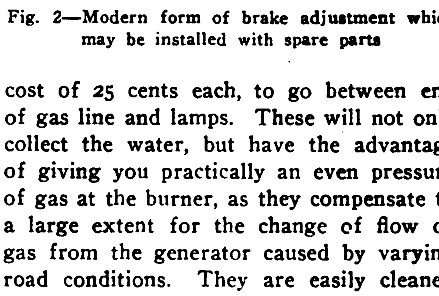

Fig. 2—Modern form of brake adjustment which may be installed with spare parts

cost of 25 cents each, to go between end of gas line and lamps. These will not only collect the water, but have the advantage of giving you practically an even pressure of gas at the burner, as they compensate to a large extent for the change of flow of gas from the generator caused by varying road conditions. They are easily cleaned and do not clog.

[2943]—J. R. Day.—If you will take out the screw block in your drag link, and the spring, you will find two concave blocks that fit about the ball on the steering arm. Take these out and fit them around the ball and see if their edges do not come together and still leave some shape. Grind down the edges until there is a space of about 1/16" between edges when fitted around ball. You will find, I think, that that remedies your trouble.

[2944]—C. J. Andrews.—If there is no drain cock on the bottom of your radiator look for a pipe plug. All radiators have some provision for drawing off water. Also look for plug under water jacket and

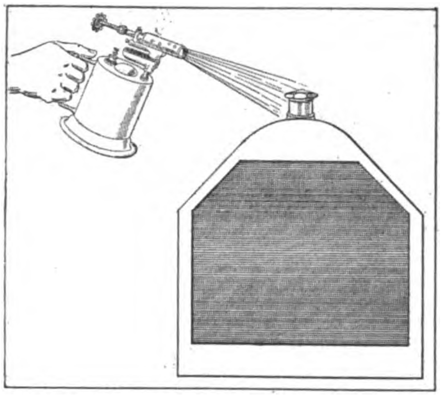

Fig. 3—Method of removing radiator cap by gentle heating with torch

between cylinders, if yours is a vertical motor, cast in pairs. If there seems to be no other way loosen hose clamp and pull hose off bottom of radiator.

New Haven, Conn. W. B. UTLEY.

Speaks from Experience

Editor THE AUTOMOBILE:

[2,972]—Referring to letter No. 2953, signed by Mr. H. L. Shepard of Rochester, N. Y., relating to trouble with his headlights on Ford car, I think that if Mr. Shepard will set his vibrators as light as possible that he will have no trouble with his magneto operating his car and lights at the same time. I have found several cases similar to his and the vibrators were screwed up so tight that the magneto could hardly operate the vibrators alone, to say nothing about lighting the lights at the same time. The vibrators should be loosened up just as much as possible and have the car run, then give them a slight turn to stiffen them up a little, sufficient to operate the car at high speed, then I think he will have no more trouble in this direction.

I do not find that the valve stems need readjustment as the wear on the valves and the grinding takes up any wear on the end of the valve stem.

Watertown, N. Y. C. D. WARNER.

Radiator Cap Stuck

Editor THE AUTOMOBILE:

[2,973]—Every time I desire to remove the radiator cap in order to replenish the supply of water before starting out I have trouble in removing the cap from the radiator. I have been hammering it lately, but do not wish to continue this as I am spoiling its appearance.

TROUBLED.

New Haven, Conn.

If you have a torch in the garage it could be lighted and then applied to the radiator cap in the manner shown in Fig. 3. Since the heat reaches the cap first it will expand before the metal upon which it is fitted. In this way you will find that it may generally be removed.

Has Trouble with Single Cylinder

Editor THE AUTOMOBILE:

[2,974]—I have a single-cylinder car with which I am having all kinds of trouble. I cannot get an explosion strong enough to give one turn. The ignition system is all right as I have a good coil and get a good hot spark. The timing also appears all right, but I do not get an explosion even when I prime the motor. M. M. J.

Salem, Mass.

Your troubles may be due to a variety of troubles and the symptoms described are not detailed enough to accurately determine their exact nature. However, the seat of trouble may lie in the fact that the compression is not good. This would most likely be the case if the motor were old. If it is a new motor, since the ignition is as it should be, the cause of the trouble may be found in a faulty carbureter adjustment.

Compressed Air Starter

Editor THE AUTOMOBILE:

[2,975]—(1) Would it be practical to use compressed air in an automobile using a gasoline engine to compress the air, superheating by means of the exhaust, and utilizing a double-acting engine for the final drive? Such an arrangement it would seem would give the utmost flexibility provided the losses are not too great.

(2) I would also ask if a two-cycle engine is constructed with a sliding sleeve valve admitting the charge of gasoline at the head of cylinder instead of through a port at the end of piston stroke?

It would seem that such a construction would make a very satisfactory motor, provided the charge is admitted through four ports on opposite sides of the cylinder simultaneously so that the currents of air entering the cylinder would impinge on each other in such a manner that the new charge would be more thoroughly diffused throughout the combustion space, and a more thorough scavenging result.

(3) Has any method of scavenging a two-cycle motor ever been put to practical use? MEDICO.

Grafton, W. Va.

(1) It would not be practicable, for even if such an outfit could be made to run satisfactorily it would have to have a 100 per cent. efficiency in order to derive as much power from the air as would be given up by the compressors of the gasoline motor, so that the motor would have to have the same horsepower as those now in use. Added to this motor would be the extra weight of the air and double-acting engine outfit which would make the whole plant too large and heavy for any self-propelled road vehicle.

(2) The complications of the manifolds necessary to carry out this scheme would more than overbalance any good which could possibly result from its use.

(3) Only in some of the larger double-acting types, such as the Koerting motors where an auxiliary air tank was employed to allow air to flow in under pressure and expel the dead gases.

What Is a Second-Hand Car?

Editor THE AUTOMOBILE:

[2,976]—You would oblige us very much by giving us a clear and concise definition of new car, demonstrator, and second-hand car. We have been having some controversy about this subject.

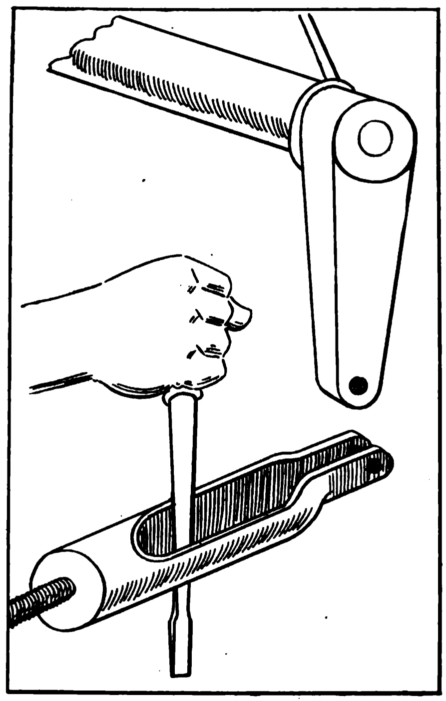

Fig. 4—Method of adjusting the old-fashioned brake fitting

One of the parties contends that a car which has been used only a short time and only for demonstrating purposes is still a second-hand machine. I think that a car cannot be called second-hand until it has been sold by an agent to an individual and then offered by him for sale the following season. BERLEW & SUNDERLAND.

Any car which has been in active use, whether for demonstrating purposes or not, cannot be called a new car. The number of miles that the car has been driven generally determines its value. Anything not new is second-hand.

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

UNDERSTAND YOUR LUBRICATING SYSTEM.—There are very few general forms of lubrication in use at the present day so that a general understanding of the principles in use in each would aid materially in giving the average motorist the general lines along which to follow should he investigate the oiling system on his new car or, in case he has neglected this important feature in his old car, to turn over a new leaf and become familiar with those principles upon which the life of the car depends to a large extent. The damage done to cars owing to the neglect of the cylinder and other lubrication far exceeds any other damage in its far reaching results. The cost of making repairs when the damage has been caused through neglected oiling of a given part is only equaled by the amount of money paid over for such damages as are caused by collision and other varieties of wreck.

Every motor car owner should understand the lubrication of his car before he takes it upon the road for the first time. If the owner does not care to drive but turns that part of the pleasure over to the chauffeur, it is upon the latter that the duty of keeping the repair bills as low as possible will fall and upon whom the life of the car depends. The general principles may be readily grasped by the average business man since they are merely a product of common sense and do not involve any dark and mysterious mechanical secrets.

The first system which may be considered since it is found to a great extent upon the cars in use today is what may be called the circulating splash system. This

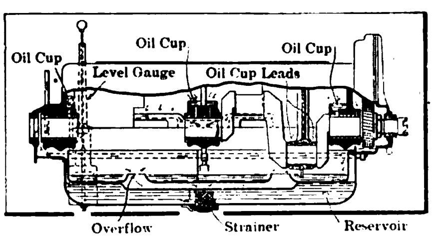

Fig. 1—Depicting the oil cups and troughs for National splash system

system is also generally known as the constant level splash system and is perhaps the cheapest system possible to install upon a car and at the same time maintain an efficient lubrication at all times. When this system is used the crankcase of the motor is generally a very deep casting in which the lower part forms the reservoir and is capable of carrying anywhere from 3 to 7 quarts of oil. The reservoir or base chamber generally slopes toward the rear of the casting so that it is deeper at this end. At the lowest point a pump which may be of either the plunger or gear type is installed. For the benefit of those familiar with the details of these two types of pump it may be said that in the plunger type the oil is sucked into a cylinder by means of a piston or plunger and then upon the next succeeding stroke is forced through a lead pipe in the direction in which it is desired to carry the oil. The gear pump, which is more commonly used for oil circulating purposes owing to the fact that ball check valves which are prone to stick are to a large part eliminated, consists of two spur gears which intermesh. The oil is drawn between the rapidly revolving gears and squeezed up through the outlet lead.

From the pump the oil is either led directly to the splash chambers or in other cases it is led to the sight feed which is generally located on the dash. The oil pump is driven from the camshaft by means of gearing or from the magneto and water pump shaft through gearing or through a vertical shaft, the lower end of which carries the gear pump and the upper end carries the timer. When the oil pump is of the plunger type it is driven through a crank or eccentric since a reciprocating motion will have to be imparted to the plunger.

The oil lead from the pump, whether it passes through a sight feed on the dash or passes directly to the crankcase, supplies the oil directly to the troughs which form the basis of this system. These troughs are so arranged that the ends of the connecting-rods in their downward sweep pass into them for a depth of about 3-16 inch. One trough is placed beneath each connecting-rod and the main oil lead which takes the supply from the pump is so designed that it will keep the trough full under all conditions of travel. The troughs are carried upon a sort of horizontal partition or tray which separates them from the lower part of the base chamber which contains the reservoir.

The rapidly revolving connecting-rods sweep down into the troughs and churn the oil into a fine spray which will be found all over the entire crankcase. This spray penetrates the cylinders and is drawn up by the pistons and distributed by the rings over the cylinder walls. The cylinder walls are thus amply lubricated and the supply of lubricant constantly renewed by the fresh supply drawn up by the pistons. The wrist pins are often made hollow so that there is a certain amount of oil which finds its way through the open ends; this will find its way through a duct which is cut through the upper connecting-rod bearing and hence lubricates the point. The lower connecting-rod bearings are generally lubricated by the scoop which is on the bottom of the connecting-rods. This scoop is hollow and permits the oil to flow through it and thence into the bearing. If there is no scoop fitted to the connecting-rod the bottom bearing cap is generally pierced by a hole through which the oil penetrates as the connecting-rods plunge into the troughs.

The camshaft and main bearings are

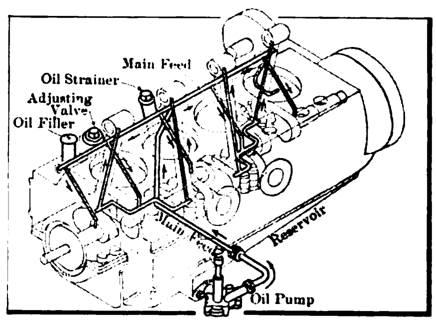

Fig. 2—Showing oil leads on the Knox cars using force-feed system

lubricated by the oil spray which will be very thick in the crankcase and will be found to reach every point in sufficient quantities to lubricate any part. In order that the supply to the main bearings will be constant, it is the custom of some manufacturers to place a small cup or pocket above them in which the oil will be caught and from which it will flow directly to the main bearings. The timing gears are often provided with either a pocket in the same manner as the main bearings or in other cases a separate lead is led to them from the pump and the oil allowed to flow into the casing and thence drain back to the troughs in the main part of the crankcase.

Since the oil is continually supplied to the crankcase in greater quantities than it is being used there would be an accumulation of oil above the troughs unless there was some means of draining it off. This is provided by a series of overflow pipes in some cases and in other cases it is provided by placing the overflow outlets in standpipes. The overflows in any case are so arranged that they will be at the correct height to take the oil away from the upper part of the crankcase before it accumulates to such a height that there will be an oversupply of oil thrown up into the cylinders which would cause them to smoke. The overflows take the oil from that part of the crankcase which contains the troughs and leads it back to the lower part in which the reservoir is found.

In this manner the oil is used over and over again, for as soon as it reaches the crankcase it will again be drawn up by the pump and sent through the oil leads again, whereupon it will finally reach the crankcase after passing through the system. From time to time more oil will have to be added to the crankcase to replace that which is burnt up or is used in other ways. If there is a sight-feed on the dash the condition of the oil will be known to the operator by his observation of the supply passing through the glass. It is necessary that the supply be renewed in the crankcase once every month. When this is done the old supply will have to be cleaned out and the crankcase flushed out with kerosene. It is a good plan to allow the motor to turn over for about 3 seconds with kerosene in the base so that the old oil

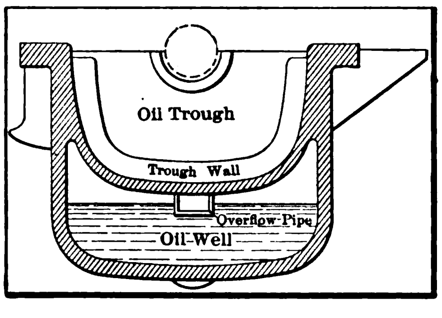

Fig. 3—Form of transverse section through crankcase of splash lubricated motor

will be flushed from the pump. The screen which is placed in the circulation line and through which all oil that enters the pump must pass should also be well cleaned out or else its purpose will be defeated owing to the accumulation of dirt which will eventually be forced through the meshes of the screen. Small details may vary on cars of different makes, but this is a general view of the splash system.

Combination Force-Feed and Splash.—This system will be found to vary very slightly from the purely splash system. The oil is generally carried in the lower part of the crankcase in the same manner as that described for the splash system. The pump is placed in a similar manner, but the oil instead of being led to the splash troughs directly is led to the main bearings through independent leads. A sight-feed is placed on the dash on some makes of cars and when this is done the type used may be either one which will show the flow to each main bearing or it may on the other hand consist of a single glass which indicates the flow as a whole.

The oil will flow to the main bearings under the pressure given by the pump. The lubrication of these bearings will hence be positive and the same under all circumstances. The oil then passes from the bearings into the troughs on either side and is picked up by the connecting-rods and thrown up into the cylinders in the same manner as described for the splash system. Overflow pipes are provided so that the oil will pass back to the reservoir from where it is picked up again by the pump after passing through the screen and thence goes through the system again.

The same precautions will be necessary in cleaning the crankcase every month in order to insure a fresh supply of oil to the motor. The drain plugs in the bottom of the crankcase will have to be removed and the old oil allowed to flow out at least once a month or after every 500 miles. The kerosene is then introduced through the oil filler hole or through the breather pipe and the engine allowed to run in the same manner as above described.

It will be seen that the splash systems and the combination do not vary to any great extent. Occasionally, however, a combination system will be found in which the oil is not only fed to the main bearings but from there passes through a hollow crankshaft to the other bearings, and occasionally up a lead along the connecting rod to the wrist pin bearing. In this case the only parts of the mechanism which are lubricated by the splash are the pistons and the camshaft bearings. The system is on the whole more of a force-feed type than a splash.

The Force-Feed System.—When this is used the reservoir may either be in the base of the motor or not, according to the method used. If the oil is recirculated the reservoir will be in the base, if not the reservoir is independent of the motor and is generally in a small tank on the side of the crankcase, but is not an integral part of the same. The recirculating type may be considered, the two principles being the same. The crankcase is not subdivided by either horizontal partitions or by vertical troughs, as is the case in the splash system of lubrication. These partitions are not required because the connecting-rod does not splash into the oil in any case as this would cause the motor to smoke. A mechanical oiler is fitted which consists as a rule of a number of small plunger pumps mounted side by side and which are all operated from the same shaft which passes through the box and upon which a small crank is fitted for each pump. A lead runs from each of the pumps to some part of the motor, either the main bearings or other bearings throughout the mechanism, and the oil will be driven through these at a pressure which may be regulated and which will vary under the different conditions of use of the car. For city driving a pressure of two pounds will be found sufficient for all cases, while in the country or for racing purposes the pressure required will be considerably in excess of this. A pressure gauge is often located on the dash in place of a sight-feed when this type of lubrication is used and the pressure on the gauge will drop when the supply of oil begins to diminish appreciably.

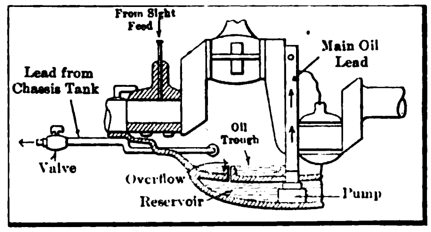

Fig. 4—Auxiliary tank used on the Royal Tourist cars with splash system

The crankshaft is made hollow and is drilled so that it will register with a similar drilled duct in the main bearing bushing. As the crankshaft turns about, there will be a quantity of oil forced into it at each revolution during the time that the two ducts are opposite each other. During the other part of the revolution the oil will flow into the main bearing itself and lubricate it. There will be a quantity of oil thus forced into the center of the crankshaft against the slight centrifugal force encountered upon entering the shaft. This oil will flow through the shaft until it reaches the crank cheeks, through which it will be thrown by centrifugal force owing to the large comparative radius of the same. The oil thus finds its way to the connecting-rod bearing. The connecting-rod is fitted with a small tube of copper, through which the oil is carried to the upper end and thus into the wrist pin bearing. Whenever the opening leading to wrist pin lead registers with the opening in the connecting-rod bearing bushing a stream of oil will be forced into the lead. This will gradually work its way to the wrist pin, which will be lubricated in this manner. The wrist pin is very often pierced by an oil hole so that the lubricant may flow through this member to the walls of the cylinder. The cylinder walls are also lubricated by the additional oil which is thrown upon them by the spray that leaves the bearings at the lower end of the connecting rod owing to the great centrifugal force at this point.

The oil flows back into the reservoir in the bottom of the crankcase and is then strained and drawn through the mechanical oiler again. The process of cleaning is carried out monthly in this system as in the splash and combination methods of oiling. The mechanical oiler should also be flushed out as well as the crankcase itself as the dirt and grit which will finally collect in any circulating system is apt to find its way into the oiler. The ball check valves in the mechanical oiler should be kept clean, as dirt stops the oil flow.

My Ideal 1912 Automobile

Readers' Conceptions of What Next Year's Car Should Be

Experienced Driver's Views

Editor The Automobile:

YOUR readers' conceptions of the ideal car interest me, and I should like to beg a little space in your valuable columns. I should like particularly to know if any of your readers are inclined to agree with me.

My views of the ideal car run thus: The motor should preferably be a six-cylinder four-cycle one, with the cylinders cast singly or in pairs. The bore should be 4 inches and the stroke 5½ or 6 inches (if a four-cylinder motor the bore should be 4½ inches and the stroke 6 inches). It should be water-cooled, copper water-jacketed, and the circulation should be maintained by means of a gear-driven centrifugal pump. There should be a tubular radiator with copper plates. The valves should be of the poppet type, 2⅛ inches in diameter, enclosed, and all on one side. The splash oiling system maintained by force-feed pump into the crankcase with sight-feed on the dash should be included. All bearings where possible should be provided with grease cups, and the ignition should be by Bosch magneto or dynamo which, through storage system, could also be used to start the car and to light it.

A Stromberg carbureter should be used or, possibly better, an individually designed carbureter built for and adjusted to the engine and with provision for an air valve operated from the driver's seat for use when coasting on compression. The clutch should be a leather-faced cone of the Renault type, and a straight-line drive; one or two protected universal joints and an adequate torsion bar should also be included. The transmission should be optional, preferably of the selective sliding-gear type, with four speeds forward and reverse, direct drive to be on the third speed with a ratio of 3.3 to 1; fourth speed over direct and geared 1.7 or 2 to 1. Or if preferred it could be selective sliding with three speeds forward and reverse, direct on third and geared 3.3 to 1.

For my own driving on a car of such horsepower I should prefer the four-speed transmission, but for the standard cars I think the three-speed would be the better on account of the fact that most of the cars would probably be purchased by men as their first cars, making it possible that they would ask too much of the over-direct and would ignore it.

The frame should be a pressed channel section steel, thoroughly reinforced, with a drop at the dash line and a rise again at the rear axle to allow the body to hang low. The body should be straight line across the bonnet and doors, thus allowing plenty of height for the seat and lessening the unsightly high seat back above the top of the body line.

Readers continue to demonstrate their interest in the ideal car and the specifications which are submitted show a wide range of taste and requirements. In view of the interest shown the Editor continues to extend the invitation to all who entertain ideas on this absorbing topic, to submit their opinions for publication. The description should be legibly written on one side of the paper and signed by the sender, although if it is so desired the name will not be published.

The steering column should have rake, this together with plenty of leg room in the front seat being the only things that will give comfort in touring. The steering wheel should be in the driver's lap, and not so far away as to necessitate reaching out or up for it. The spark and throttle levers should be on the steering wheel on a semicircle, the same to pull toward the driver to open the throttle and to advance the spark. The drive should be right hand, with the gear control levers also on the right. If necessary, however, to keep the body narrow, these latter could be put in the center. The wheels carried should be 37 inches by 4½ inches or 38 inches by 5 inches, with quick detachable tires. The front axle should be of the ball-bearing type, I-beam section, while the rear axle should be a full-floating Timken. The brakes should be internal expanding and external contracting on the rear axles, the brake drums being 18 inches by 2½ inches.

The gasoline should preferably be fed by gravity, but if necessary to keep the body low pressure feed should be employed. A gasoline gauge should also be placed on the dash. The wheelbase should be from 124 to 130 inches. The car should be fully equipped with top, wind shield, speedometer, etc.

Jersey Shore, Pa.

Has Views of His Own

Editor The Automobile:

Perhaps I am a little late in expressing my views of the 1912 car, but I trust that you will see fit to publish them nevertheless.

As I do a great deal of driving regardless of the weather I would prefer a car having a little reserve power, say one with from 40 to 50 horsepower. The motor should be of the improved water-cooled, six-cylinder type, and it should be a T-head affair. The valve springs should be inclosed in such a manner as to be easily accessible if need be. I would prefer that the cylinders be cast in pairs, as I am not very favorable to the monoblock construction. The Knight type of engine would be preferable, also, as it is the coming type on account of its noiselessness and smooth running. The size of the cylinders should be 4 inches by 5½ inches, and while this is not an extremely long stroke it seems to be amply long enough for proper fuel economy and for best power output at all loads.

The ignition should be by the Bosch dual system, which system should also be used to light the headlights. The lubrication should be by a combined splash and force-feed system, and it should be so designed as to positively force the oil to the cylinder walls and the bearings. Small scoops should be fitted to the crank ends of the connecting-rods to dip oil from the reservoir. The clutch should be a multiple disk one, with 61 plates running in oil. The housing for this should be so constructed as to prevent any leakage of oil.

The transmission should be of the selective type and there should be three speeds forward and a reverse. The drive should be by shaft, and there should be two universal joints included.

Semi-elliptic springs should be used on front and rear, and the rear axle should be floating. A B. & L. Castor front axle seems very desirable to me, as I have seen to my satisfaction that it reduces vibration and makes steering much easier, especially over rough roads. A wheelbase around 140 inches seems about the correct thing to me, as it allows ample seat room and leg room. Tires to carry should be 36 inches by 4½ inches.

The control should be in the center of the car, since this makes for simple chassis construction, as well as making it easier for the driver to get into his seat. The steering wheel should be on the right, and it should have mounted on it the usual spark and throttle levers. The body should have ample seat room for five passengers.

I would specify the usual equipment of speedometer, lamps, horn (Klaxon), compressed air self-starter, two extra quick-detachable tires, robe rail, tire irons, waterproof top, windshield, gasoline gauge on dash, clock, trunk rack, etc.

Possibly the price of this car would run up to as high as $5,000, but I think it would be worth the money. K. L. S.

Washington, D. C.

Oxy-Acetylene Welding and Cutting

WHILE the oxy-acetylene flame, by reason of its manageability and intense heat, has proved exceedingly convenient for the performance of welding and metal-cutting operations, even such as a short time ago were beyond the resources of an ordinary machine shop or factory, an exaggerated idea of the simplicity of the equipment required for the production and utilization of this gas mixture has resulted in an influx upon the markets, in most industrial countries, of many troublesome apparatuses, which are usually offered at a tempting price, as sufficient for all needs. As an offset to this condition, some of the technical publications in Europe are now furnishing descriptions and explanations of good practice in this new branch of work, and, while the descriptions are perhaps in no instance completely up to date—since new developments appear from day to day—they illustrate the technical requirements of the work and enable the readers to steer clear of devices in whose design, materials and workmanship there is no evidence to show that the makers have investigated anything but the vogue of this class of apparatus.

Some extracts with illustrations from German articles of this kind are presented in the following, though it may be noted that the German writers agree on recognizing superiority in the British practice so far as the hand tools are concerned which are employed for the work.

WELDING—A welding tool which was first shown at the British Olympia exhibition one year ago and which has been found convenient and durable is represented in Fig. 1, including a sectional and a top view and two detail sections. The two inlet pipes, a for oxygen and b for acetylene, are connected with the gas generators or tanks. The oxygen passes through the control valve c and the tube d to the injector nozzle e, issuing from which it mixes with the fuel gas coming by way of the cock f and the tube g. The now united gases, whose quantities can be accurately regulated at c and f, are carried out into the expansion space h which extends from the bent mouthpiece i into the copper discharge nozzle k. By virtue of the oblique position of the mouthpiece, the tool can be placed in any angular relation to the work, from 0 to 70 degrees, without interruption of the flame. By loosening the knurled nut l, the mouthpiece can simply be turned around to the desired position. This is especially of value if the work cannot so readily be turned around.

Many universal welding tools, intended to be operated with different mouthpieces according to the requirements of the work, are offered in the market, but the frequent exchange of mouthpiece soon affects the screwthreading, and in some of them backfiring is liable to occur, the flame striking back into the mouthpiece and continuing to burn, so that the welding is interrupted and often spoiled, while the tool must be cooled before it can be used again. Even if an accurate adjustment of the oxygen supply is possible in a universal burner of the kind referred to, more skill is required as well as more time for making the adjustment correctly than if a special tool, intended for only one mouthpiece and a limited range of gas adjustment, is used. Considering the influence upon the work of unsuitable adjustment and the fact that the oxygen is the most expensive material used in the process, and that this material is wasted if the regulation of its feed is in any manner rendered difficult or inconvenient, it is not surprising that the best practice runs to the use of complete special tools for each kind of work which may be required in a shop. In this connection it is notable, too, that the different metals on which work is done naturally requires different quantities of gas for maintaining the heat required in each case over a given area of welding surface.

Among German advertisements are noticed some in which bottled and compressed oxygen is offered the trade for welding purposes, the bottles being either sold or rented, while on the other hand the acetylene gas is usually produced in generators which form part of the welding plants as they are offered for sale. These generators may be classified in four types, which, however, are of very unequal value in furthering and safeguarding the work for which they are intended. Only the system by which the calcium carbide is automatically fed in small quantities to a large volume of water can be considered as advantageous. The feed is adjustable, and the gas is generated only in small quantities corresponding to the demands of the work in hand. It therefore remains cool. The gas as fast as produced gathers under a floating bell. No after-development of gas takes place. The generator is always ready for new work without other preparation than the adjustment of the feed. In apparatus of this type the principal thing to look out for is that it includes no ropes, rollers, springs, valves, levers, cogwheels, stuffing boxes and rubber packings, but only water joints. The size of the carbide used should not be less than 10 millimeters (1-2 inch). Apparatuses with feed cocks and tubes or hose always

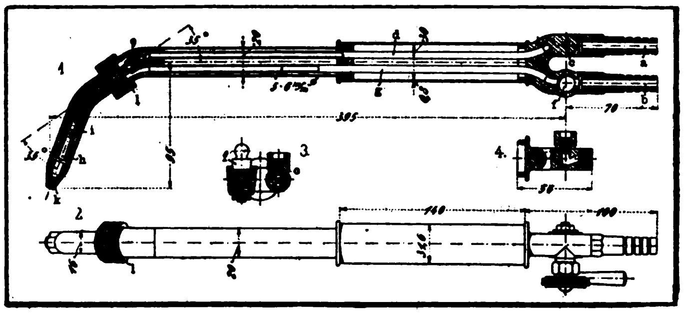

Fig. 1—Autogenous welding tool—dimensions in millimeters

require fine-grained carbide which remains in part dry on top of the water surface upon which it falls.

A variety of this type in which all the carbide required for the contemplated work is thrown into the water at once requires a large water reservoir to keep the gas cool and a large gas bell. It is lacking in compactness and calls for skilled judgment in estimating the carbide required, if interruption of the work is to be avoided.

The other systems represented in the market are the dipping system by which the carbide container is submerged in the water until a sufficient volume of gas has been generated and is then withdrawn; the expulsion system by which the water enters into two or more carbide containers from below and is expelled only by the gas pressure developed above it, and the combined dipping and expulsion system which combines the disadvantages of the two previous ones. These relate mainly to the after-development of a gas, which is generated under heat and is not acetylene (C_2H_2) but ethylene (C_2H_4) and has a harmful influence on the quality of the work, and to the necessity for frequent readjustments which interfere seriously with both quality and output. A disagreeable odor in the shop, from escaping gas, should also be mentioned. These methods all waste carbide through insufficient wetting.

With all systems, a simple method for getting rid of the carbide sludge should be provided. The simplest is a drain through which the sludge is washed out with the water.

CUTTING—A metal-cutting tool is shown in Fig. 2, including two sectional views of the tool in its entirety and three details.

The working principle is that the oxygen, entering under pressure at S entrains the fuel gas in the required quantity, so that a good mixture of both gases flows under sufficient pressure into the burner nozzle. The valve through which the oxygen is admitted can be regulated in two ways; first, by the knurled knob a which turns the valve spindle b, secondly, when this method is preferable, by first screwing the spindle b home in the threaded passage provided in the handlever c and then operating b up or down by means of this handlever, and by this method it is possible to shut the oxygen completely off by a single movement.

The details of the mechanism may be followed on the drawings. The valve spindle b is normally held open by a spring e secured in the bottom of the distribution chamber by a screw cap and bearing against a packing which acts upon a boss at the end of the spindle. The gas channels i and k, respectively for fuel and oxygen, are both provided with regulation cocks, l and m, the latter affording a different regulation for the oxygen from that which the spindle b places at disposal, as will be readily understood from the following. The fuel gas passes through k to the chamber p, while the oxygen, passing through the two openings regulated by spindles m and b respectively, flows into the separate channels s and t and thence to the end apertures of nozzles d and n. The channel t carries the oxygen intended for burning metal away and is discharged through the central nozzle d directly upon the work, while the oxygen flowing through channel t and serving to generate heat for melting the metal is first mixed with the fuel gas coming through the passages in the enveloping tube w, the mixing taking place in

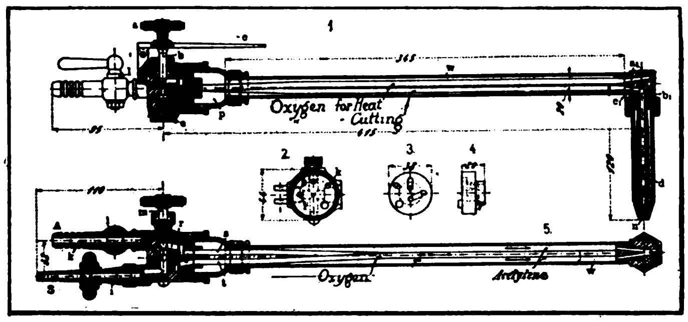

Fig. 2—Oxy-acetylene metal-cutting tool—dimensions in millimeters

the expansion space b1 in the back part of the mouthpiece a1 and flowing from here into the annular space between the nozzles d and n. In the interior of the distribution chamber o, a connecting block is inserted which leads the gases from i and k in the manner explained, as shown more definitely in the small detail sections of Fig. 2.

The special advantages of this tool are the convenience and accuracy of the gas flow regulation and the ease with which the mechanism can be taken apart and again assembled.—From *Der Praktische Maschinen-Konstrukteur,* October 12.

Blackening Copper, Brass and Other Metals

With a pronounced tendency observable toward the avoidance of bright and shiny equipment for automobiles, the merits of various methods for imparting a black and permanent casting to the otherwise shiny parts naturally claim attention, and as it is a comparatively inexpensive process to copperplate most of the metals utilized for these parts the best means for blackening copper are considered in the first line. On this subject Bavarian Leaves of Industry and Trades (*Baye ische Industrie und Gewerbeblaetter*), No. 43, offers information of a wet process with an alkaline solution which may be considered preferable to the well-known blackening process with nitrate of copper or nitric oxide and is more broadly applicable than the blue black etching process with an ammonia solution of copper which can be used only for alloys containing zinc.

The directions with regard to articles with a copper surface are given as follows: A suitable quantity of a 5 per cent. lye of sodium carbonate (sal-soda) is heated to 100 degrees centigrade in a vessel of glass, porcelain, stoneware or enameled iron. Hereto is added 1 per cent. of powdered persulphate of potash, and the article is dipped in the bath suspended from a wire, so as not to touch the vessel. A visible generation of oxygen follows. The article is moved to and fro until the desired black color is obtained; in the case of small articles usually about five minutes. If the generation of oxygen is seen to lag or cease before this stage is reached, 1 per cent. of persulphate of potash must be again added. The velvety looking article is now rinsed in cold water and wiped dry with a soft cloth, acquiring a deep-black matt luster.

If the bath has not been exhausted and it is desired to use it again (with more persulphate of potash) it should be kept covered, so as to protect it against absorption of carbonic acid gas from the atmosphere.

Defective action, as may occur, may be due either to the lye or to the metallic surface. By continued use of the lye, the free alkali which is necessary for the action is neutralized by absorption of carbonic acid, or the alkaline bath is for other reasons deteriorated in course of time by generation and discharge of gas. In this case a new bath must be prepared.

Defects due to the condition of the metal surface are caused by thin films of oxide. It is best to prepare the metal by cleaning it in dilute sulphuric acid. Copper which has become tarnished by exposure or in a soldering process also accepts the etching process defectively. In contrast to the disturbing films of oxide, the brown coatings of protoxides obtained by the wet browning process accelerate the formation of black oxidation from the persulphate of potash bath, but the coatings formed on this foundation are somewhat less lustrous than those formed direct on metallic copper.

Zinc, tin, aluminum, iron, nickel, German silver, spelter and solder cannot be oxidized black by the persulphate of potash method, but some of the alloys of copper with these metals may be successfully treated. Those in which copper predominates, including the dark bronzes and gunmetal, accept the black coating like copper, but the process requires somewhat longer time, usually from five to ten minutes.

Brass and aluminum bronze require a bath in which the strength of the sodium carbonate bath has been raised from 5 per cent. to 10 per cent.

Pure or nearly pure aluminum is dissolved in the bath under a violent generation of oxygen.

Articles made of zinc may be blackened very successfully if previously copper-plated; but the copper coating must not be too thin, as a portion of it goes into solution in the bath. The electrolyte in which it is produced may, on the other hand, be either acid or basic. Copper articles in which there are seams of solder should also be plated first, as the solder will not accept the etching. And the plating is also the simplest method for removing the films of oxide which are usually formed on a soldered article and which would otherwise interfere with the blackening. To copper by dipping is not recommended, as the coat so formed is too thin and is usually also marred by spots of oxide which spoil the uniformity of the black coat.—From *Metall-Technik,* October 14.

Firm, Clean Aluminum Castings.—To get rid of the oxides which form on top of molten aluminum and get into the interior of the castings poured from it, the modern foundry man keeps a well stoppered bottle with chloride of zinc in pieces of about the size of a walnut, and when the aluminum reaches the fusion point, he picks out a piece with a tong—as the material attacks the skin—drops it into the molten mass and stirs the latter vigorously. Considerable smoke is developed by this process, but the bath becomes clean and mirror-like as molten tin, while the chloride gets black and floats to the edges of the crucible and the oxide turns into a powder which is simply brushed off before pouring.—From *Metall-Technik,* Oct. 28.

Waterproof Materials

In these modern days when serviceable substitutes for leather, varnishes and rubber are being sought by inventors, largely in connection with the production of articles intended for use in or with automobiles, the extensive application which has been found for casein is of interest. Mixed with soap and oils this substance is now much used for the sizing of textile goods. Four parts of casein with 30 parts of water and 1 part of chalk, mixed in a soap solution, make such a sizing, and if the fabric is subsequently plunged into a solution of acetate of aluminum, the casein is thereby rendered insoluble and the material can be washed in water and dried. The readiness with which the insolubility of the casein can be effected in any desired degree either by oxidation or by the action of formaldehyde is taken advantage of for producing materials which are to be permanently impermeable to water while admitting the passage of air.

Calicos and other materials which have always been prepared with albumen, derived from blood, to protect their colorings, are now in some cases treated with casein, which has proved cheaper, cleaner and better, and it is probably only a question of time before similar methods will be used for impregnating other fibrous material which should resist weather and water.—From *L'Industrie Textile,* August 15.

Production of Coal Tar

An inkling as to how far the actual production of coal tar will go in the improvement of roads may be had from British statistics on the subject. In 1889 there was an overproduction of the tar, and it was contemplated to turn it to use as fuel. Since then the tendency has been to reduce the tar production at the gas works, while the steel mills turn it out in ever increasing degree. The coal output of Great Britain rose to 263,774,000 tons in 1908. Out of this total 1,500,000 tons were used at the gas works. The total tar production was at the same time 1,100,000 tons, of which 750,000 tons came from the gas works, 150,000 tons from the coke ovens and 200,000 tons from the steel mills.—From *Bulletin of the Chemical Society,* II, 1911.

LUMINOUS PAINT.—By mixing pulverized phosphorescent material, such as sulfide of calcium, phosphoretted zinc or sulfide of barium, together with a trace of bismuth, with a binder material such as gelatine, lac, gelose, etc., a paint or gouache (water color body) is obtained which may be used for rendering any part of an automobile luminous in the dark, provided it has been exposed to the rays of light or heat previously. It may be varnished over or not, and it is not affected by rain or weather. The color may be any one desired. Georges Garfounkel has the French patent. —From *Chimie Industrielle,* September.

Calendar of Coming Events

Shows

Dec. 30-Jan. 6......Buffalo, N. Y., Annual Show, Seventy-fourth Regiment Armory, Buffalo Automobile Trade Association.
Jan. 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 13-19.........Milwaukee, Wis., Auditorium, Fourth Annual Show, Milwaukee Automobile Dealers' Association
Jan. 13-27.........Philadelphia, Annual Show, First and Third Regiment Armories, Philadelphia Automobile Trade Association.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 15-20.........Toledo, O., Annual Show, Terminal Building, Toledo Automobile Dealers' Association.
Jan. 22-27.........Rochester, N. Y., Annual Show, State Armory, Rochester Automobile Dealers' Association.
Jan. 22-27.........Detroit, Mich., Wayne Gardens, Eleventh Annual Show, Detroit Automobile Dealers' Association.
Jan. 22-27.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Jan. 22-27.........Dubuque, Iowa, Annual Show Dubuque Automobile Dealers' Association.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 27-Feb. 10....Pittsburgh, Pa., Sixth Annual Show, Automobile Dealers' Association of Pittsburgh, Inc. Pleasure cars, first week. Commercial vehicles, second week.
Jan. 29-Feb. 3.......Scranton, Pa., 13th Regiment Armory, Second Annual Show.
Feb. 1-7...........Washington, D. C., Annual Show, Convention Hall.
Feb. 3-10..........Montreal, Canada, National Show, Drill Hall, Automobile Club of Canada.
Feb. 3-10..........Harrisburg, Pa., Third Annual Show, Arena.
Feb. 5-10..........Buffalo, N. Y., Convention Hall, George C. Fehrman.
Feb. 5-17..........St. Louis, Mo., Coliseum, Annual Show, Pleasure cars, first week. Commercial vehicles, second week.
Feb. 10-17.........Atlanta, Ga., Auditorium-Armory, Atlanta Automobile and Accessory Dealers' Association.
Feb. 12-17.........Ottawa, Ont., Howick Hall, Annual Show, Ottawa Valley Motor Car Association.
Feb. 12-17.........Kansas City, Mo., Annual Show, Combined Association of Motor Car Dealers.
Feb. 12-17.........Troy, N. Y., Second Annual Show, State Armory, Troy Automobile Dealers.
Feb. 12-19.........Dayton, O., Third Annual Show, Dayton Automobile Club.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 17-24.........Pittsburgh, Pa., Second Annual Show, Exposition bldg., Pittsburgh Auto Show Association, Inc.
Feb. 17-24.........Newark, N. J., Fifth Annual Automobile Show, New Jersey Automobile Exhibition Company, First Regiment Armory.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Feb. 19-24.........Omaha, Neb., Seventh Annual Show, Auditorium, Omaha Automobile Show Association.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Feb. 19-24.........Cincinnati, O., Annual Show, Music Hall, Cincinnati Automobile Dealers' Association.
Feb. 20-24.........Binghamton, N. Y., State Armory, Third Annual Show, Automobile Dealers' Association.
Feb. 20-28.........Baltimore, Md., Annual Show, Baltimore Automobile Dealers' Association.
Feb. 21-24.........Louisville, Ky., Fifth Annual Show, First Regiment Armory, Louisville Automobile Dealers' Association.
Feb. 21-28.........Toronto, Ont., Annual Show, The Armouries, Toronto Automobile Trade Association.
Feb. 24-March 2...Brooklyn, N. Y., Twenty-third Regiment Armory, Annual Show, Brooklyn Motor Vehicle Dealers' Association.
Feb. 26-Mar. 2.....Elmira, N. Y., Second Annual Show, Elmira Automobile Club.
Feb. 26-Mar. 2.....Paterson, N. J., Annual Show, Fifth Regt. Armory. Paterson Automobile Trade Association.
Feb. 26-Mar. 3.....Quincy, Ill., Highland Park Stone Pavilion, Annual Mississippi Valley Show, Quincy Auto Club.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

The Get-Together Spirit

WITH the return of Christmas and New Year's the mind naturally turns to review the affairs of the year, the progress of the seasons, the forces that have been the molding influences, the factors that have been for good or ill during the previous twelvemonth. The year just drawing to a close has been fraught with much of interest insofar as the automobile is concerned; it has shown more unity of purpose among the makers than has ever been evidenced before and it has been a year of real progress. There has been in evidence more of a spirit of get-together than ever before. The engineers set the ball rolling in this co-operation scheme through the excellent work of the Society of Automobile Engineers. The midsummer convention and the recent trip abroad have both proven the value of a good interchange of ideas; both have taught the members that strength is in unity and not in isolation. The days when the engineer wanted to play the rôle of the Pharisee are over. This society has been the means of bringing to light some of the profoundest secrets of the industry. Only a year or so ago many engineers refused to even discuss many of their ideas with their intimate friends. They seemed to imagine that they possessed the only solution of the motor, the ignition, the carbureter or the self-starting problem and that if they opened their mouths the magic would depart from them. This old rule is passing away. The new wine is too strong for the old bottles and the rising engineers are men not afraid to meet face to face with others and give their opinions of present tendencies and trends.

What the engineers are doing the sales managers could do to great advantage. If there is any department of the industry in which new ideas and new blood are needed it is in the sales departments. The fossils have one by one been dropping off for the last 18 months, but the trouble is to get new blood to take their places. New salesmen are needed in every city—salesmen who have address, who have knowledge, who are students of psychology and who have ability. It would be a good investment if all of the factories would appoint their sales managers delegates to a convention in which the fine art of salesmanship would be discussed from every angle. Education of the masses is the big need. There are a few who know, but for each one who knows there is a score who do not know. Conventions of this nature would be a great investment to the industry—an investment that would pay twenty, thirty or fifty-fold. Some say that such a convention would be impossible; that the head salesmen could not be brought together; that if they should convene those who know would refuse to give away their knowledge to those who do not know, and that the entire scheme would be a failure. Many talked in this strain before the Society of Automobile Engineers attained its present standing. The facts have proven otherwise, and although many of the engineers refused to discuss matters at the start and although many still refuse to enter into such discussions, still there has been much good come of the discussions that have taken place, due to the general freedom of speech and expression that has been developed since the society began its work. What has happened with the engineers would happen with the salesmen. That is the one big reason why such a convention should be encouraged.

Among others prominent in the industry who should get together are the automobile dealers in the big cities and towns in the different parts of the country. The dealers are the least prosperous class connected with the industry. Many of them are poor because they worked to make themselves so. They should not be disappointed when the harvest reaped is the natural result of their actions. Many, yea, scores and even hundreds, have bitten on the second-hand car proposition. Not a few have tied up all of their profits in the used cars they have taken in part payment for new ones, and at the close of the season they find themselves unable to make the necessary deposits on 1912 cars. Scores of the dealers imagined that they had to keep cars moving off the salesroom floor. One was frank enough to say that his actual profit on the sale of a new car was $2.70. This is not much of a margin on which to pay rent, pay sales, office and garage employees, pay insurance and a hundred other expenses in conjunction with a salesroom, and live and lay aside something for the future.

The dealers should make money. They are the people who are closest to the buying public. They are the thermometer by which the public gauges the standing of the industry. If the dealers are poor, the business men will naturally estimate the industry accordingly. Dealers should get together and better their lot. If the factory is not giving them a fair show, then the best way to get justice is to get together and demand those rights which are rational and just. The dealers will get more if they band together than if they act single-handed. Only a few weeks ago a great many of the Secretaries of States from scores of states throughout the country met to study the best laws for the control of automobiles. They talked the laws over. The pros and cons were well discussed. The man from New York learned from the man from Illinois, and the Oklahoma delegate got many points of information from the Connecticut delegate. All went home filled with ideas. The man who gave to others his good ideas was perhaps happier than he who went home loaded to the guards with facts. What can be done for legislation can be done for the dealers. A big dealers' convention should be called in Chicago. It is the most central point. A national organization, for the purpose of controlling such conventions, should be planned. A good sensible program should be arranged, and each dealer attending would find himself amply repaid for the time and money expended.

"Know your business better" is the slogan of the motor car business. One dealer acknowledged a week ago that he never knew exactly what departments of his business were making money and what departments were being operated at a loss. He put on an accountant. He was amazed at the results. Departments that he imagined to be self-sustaining were draining the more fruitful ones. Once he knew where he stood it was possible to make investigation into the causes of the loss and prescribe remedies.

Every dealer should look to this department of his work. He should systematize more. With increasing competition more efficient management of branches and salesrooms is imperative. It will require more brains to make money as a dealer during the coming year than it did last year. Real effort is needed.

S. A. E. Shows Remarkable Growth

THE Society of Automobile Engineers will close the year with nearly 1,200 members. Applications for membership are coming in at the rate of 100 a month.

The annual meeting of the society will be held in New York, January 18-20. This is during the week of the commercial vehicle division of the automobile show at Madison Square Garden. The sessions of the society will take place in the assembly hall of Madison Square Garden. The program follows:

Disintegration of Fuel Particles and Homogeneous Carburetting of Air, by Forrest A. Heath.

Standardization of Drawings, by George W. Dunham.

Compound Gas Engines and Their Efficiency, by Eugene P. Batzell.

Present Status of Automobile Lighting, Gas and Electric, by J. W. Esterline and A. E. Berden.

Position of Brakes; Double-rear-wheel versus Propeller-shaft; Front-wheel Brakes, by S. I. Fekete.

Definitions in Connection with Physical Properties of Steel, by Henry Hess.

Mechanical Points in Connection with the Construction of Solid Motor Tires, by Charles B. Whittelsey.

Silent Chains, by Chester S. Ricker.

Automatic Spark Advance, by Lon R. Smith.

Underslung Frames, by S. I. Fekete.

Balance of Motors, by Ernest R. Fried.

Self Starters for Gasoline Motors, by J. W. Fitzgerald.

Multiple Disc Clutches, by Joseph A. Anglada.

The following divisions of the now famous Standards Committee will have reports to present:

Ball and Roller Bearings, David Fergusson, chairman.

Broaches Division, C. E. Davis, chairman.

Carbureters Division, G. G. Behn, chairman.

Frame Sections Division, J. G. Perrin, chairman.

Iron and Steel Division, Henry Souther, chairman.

Miscellaneous Division, A. L. Riker, chairman.

Subjects in connection with report of miscellaneous division: Standard Gauge Tread for Pleasure and Commercial Vehicles, Electric Lighting Outfits, Magneto Dimensions, Spark Plug Thread Tolerance, Vehicle Taxation Formula, Metal Gauges, Oversize Standards for Pistons, Bushed Yoke and Eye Rod Ends, Limits for S. A. E. Screw Threads.

Nomenclature Division, H. E. Coffin, chairman.

Seamless Steel Tubes Division, H. W. Alden, chairman.

Springs Division, A. C. Bergmann, chairman.

Truck Standards, W. P. Kennedy, chairman.

Advantages and Disadvantages of Large Driving Wheels; Increasing the Utility of Commercial Cars by Auxiliary Loading and Unloading Devices, by E. W. Curtis, Jr.

General Problem of City Freight Transportation.

Several hundred members are expected from all over the United States. Henry Souther, president of the society, will preside over the deliberations. The annual election of officers will be held during the session. A feature of the meeting will be an account of the first European visit of the society. The subject will be introduced generally by Henry F. Donaldson. Then several points of live technical interest will be taken up. Wire wheels for motor cars will be discussed and the results of some new comparative tests of crushing and dishing strength of hickory and wire wheels will be submitted. C. B. Hayes and Bert Morley will take part in the discussion of this subject. The subject of slient chains for accessory motor drives and for gear boxes will be taken up. The worm gear drive will be discussed by David Fergusson, E. R. Whitney, C. E. Davis and W. C. Baker. Sleeve-valve motors will also be treated at considerable length, H. E. Coffin, Henry Souther and J. B. Hull entering into the discussion. Minor points and peculiarities of European motor-car design and construction will be pointed out and analyzed. A group of the American automobile engineers visiting Europe was the commercial vehicle division.

Death of Georges Dupuy

The death of Georges Dupuy is announced in *L'Auto* of December 13. Dupuy was widely known to members of the American automobile industry, having worked for several years as a writer for various automobile journals in this country, while later he returned again to inspect and describe American factories for *La Vie Automobile*, *L'Auto* and other French journals. He was the master of a very vivacious style, especially in French, and embraced all sports as well as philosophical economics in his repertoire. He was sent by *Le Figaro* to Reno to report the Jeffries-Johnson fight, and his description of this encounter was considered an exceptional piece of work.

H. W. Whipple Suddenly Stricken

BOSTON, Dec. 26—Harlan W. Whipple, one of the early presidents of the American Automobile Association, died suddenly last night of heart trouble while visiting at the home of Col Smith M. Decker, at Lawrence. The latter's home is near that of Mr. Whipple. Mr. Whipple was just preparing to go home when he was stricken.

In the early days of motoring Mr. Whipple became a devotee of the sport. He gained prominence and was elected President of the American Automobile Association in 1904. That same year he led the contestants in the famous run to the St. Louis exposition, driving car No. 1. In 1905 he was re-elected President of the A. A. A.

He was born at South Dartmouth, Mass., Oct. 8, 1865, graduated from Phillips, Andover and Williams College, then entered business first in Chicago, next in San Francisco and finally at New York.

Planning Ocean-to-Ocean Highway

PHOENIX, ARIZ., Dec. 26—Eighty-four delegates from Arizona, California and New Mexico met in the State Capitol at Phoenix, December 20 and 21, and formed the Ocean-to-Ocean Highway Association. The main object of the association is to work for the construction of a transcontinental automobile highway passing through the three states represented.

It was left to the three delegates to decide upon the route to be taken by the highway in each state. Arizona and New Mexico had no trouble in reaching an agreement, but eleven California delegates withdrew from the organization when the convention refused to receive their minority report.

Governor Richard E. Sloan of Arizona issued the call under which the convention was held. He called the delegates to order at 10 o'clock Wednesday morning and the business in hand was transacted with astonishing rapidity. The following officers were elected: President, John S. Mitchell, Los Angeles; secretary, J. S. Conwell, Los Angeles; treasurer, A. W. Ballard, Phoenix; vice president for California, A. G. Spalding, San Diego; vice president for Arizona, Del M. Potter, Clifton; vice president for New Mexico, D. B. Sellers, Albuquerque. The legislative committee chosen consists of Stoddard Jess, Los Angeles; Thomas Early, Pasadena; F. A. Miller, Riverside; A. W. Balfour, Pomona; Rufus Choate, San Diego. All the members of this committee are Californians.

One of the first acts of the convention, after President Mitchell took the chair, was to unanimously select Santa Fe, New Mexico, as the place for the second annual convention, to be held the third week in October, 1912.

When the convention adjourned in the afternoon it was with the understanding that the three delegations should caucus and endeavor to agree upon the route through each state which they wished the national highway to take. It had already become apparent, however, that the California delegation was hopelessly split. The eight delegates from San Diego and three from the southern part of the Imperial Valley were in the minority. Knowing themselves outnumbered, they refused to caucus with the majority.

Next morning the California majority, the New Mexico and Arizona delegations presented their reports, which were approved by the convention as read.

The New Mexico route recommended in the report starts at the Arizona line sixteen miles east of Springerville and proceeds eastward to Magdalena, Socorro, San Antonio, Carthage and Albuquerque; thence to Santa Fe, Las Vegas and Raton, leaving the state on the old Santa Fe trail twelve miles north of Raton on the Colorado state line.

Following is the Arizona report: "Resolved, That the transcontinental highway, in crossing the state of Arizona, shall begin at Yuma on the Colorado River and run thence along the course of the state highway as heretofore surveyed to the city of Phoenix, thence by way of Tempe and Mesa to the Roosevelt dam, thence to the city of Globe over the state highway already constructed, thence to San Carlos on the Gila River, thence up the Gila Valley to Clifton, thence northerly to Springerville, thence easterly to the Arizona and New Mexico line to form a junction with the highway as constructed through the state of New Mexico."

The California majority report follows: "Whereas, the California delegation of the Ocean-to-Ocean Highway Association, in caucus assembled, believing that the route presenting the fewest geographical and physical obstacles should be endorsed for the national highway, having under consideration the advantages of having such a highway pass through as much settled territory as possible, and within striking distance at all times of a transcontinental railroad, therefore be it

"Resolved, That the California delegation recommend as a course for the national highway a route running westerly from Yuma, along and near the Southern Pacific railway to a point about 4 1-2 miles west of Mammoth station, thence southwesterly to Brawley, thence northwesterly along the south and west side of Salton Sea to Mecca, thence along the main line of the Southern Pacific railroad to Beaumont, Redlands Junction, Colton, thence by shortest road to Los Angeles."

San Diego endeavored to present a minority report recommending that the route in California start at Yuma and proceed through the southern part of the Imperial Valley, El Centro and Holtville, on to San Diego. As the San Diegoans had refused to caucus, the minority report was not received. Thereupon the San Diegans announced that they would withdraw from the organization. A. G. Spalding, vice president for California, and Rufus Choate, member of the legislative committee, would not serve, they said.

It is not the intention of the association to immediately ask for federal aid in building the transcontinental road through Arizona, New Mexico and California.

Rough drafts of articles of association and by-laws for the organization were drawn by a committee appointed for that purpose and approved by the convention. To Mr. Norris was entrusted the work of whipping them into legal form. The rough draft sets forth the object of the Association as follows:

"First: That establishment of a system of national highways which shall traverse the states of California, Arizona and New Mexico and such other states as may choose to affiliate themselves with and become a part of this organization.

"Second: For the establishment of a uniform system of road building, which system of road building shall be uniform and meet at given and common points to be established by the states of California, Arizona and New Mexico, said points to be established by the several states.

"Third: To obtain federal aid and co-operation toward the establishment of a system of interstate roads between the states of California, Arizona and New Mexico and such other states as may affiliate themselves with this organization.

"Fourth: To obtain the co-operation of all states in the Union for the purpose of obtaining federal aid toward the establishment of a series of national highways traversing the United States of America and to that end we earnestly request the co-operation of all states in the Union and assure them of our hearty co-operation in bringing about said highway to promote the objects of this organization."

On Wednesday evening the delegates to the convention were entertained at a banquet by the City Club of Phoenix.

Pennsylvania Surveys Roads

YORK, Dec. 26.—Engineers of the Pennsylvania state highways department have completed the surveying of sixty-five of the routes for main highways carried by the Sproul main highway act of 1911, according to a report just made to Highway Commissioner E. M. Bigelow, by Samuel D. Foster, chief engineer of the department. Included in these sixty-five routes are 2,755 miles, all of which have been surveyed, and of this length 621 miles has been plotted.

All these dirt roads will be taken by the state June 1 next and maintained by the state highway department. The toll roads will not be surveyed until they have been taken over by the state, as they will have to be purchased from the various companies owning them.

The routes surveyed include the following: Sunbury to Danville, Bloomsburg to Wilkes-Barre, Scranton to Montrose, Bloomsburg to Laporte, Sunbury to Williamsport, Wellsboro to New York state line, Lewisburg to Sunbury, Harrisburg to Carlisle, Carlisle to Chambersburg, Chambersburg to Maryland line, Gettysburg to Maryland line, Bedford to Hollidaysburg, Ebensburg to Hollidaysburg, Huntingdon to Hollidaysburg, Clarion to Franklin.

Pittsburgh to Butler, Butler to Mercer, Mercer to Ohio line, Mercer to Meadville, Meadville to Franklin, Meadville to Erie, Erie to Warren, Warren to Smethport, Smethport to New York line, Ridgway to Emporium, Coudersport to Wellsboro, Washington to Waynesburg, Waynesburg to West Virginia line (2), Uniontown to Washington, Washington to West Virginia line, Washington to Beaver.

Gettysburg to York, Philadelphia to Media, Philadelphia to Maryland state line, West Chester to Delaware state line, York to Harrisburg, Philadelphia to Doylestown, Doylestown to Easton, Philadelphia to Delaware line, West Chester to Maryland line, Harrisburg to Lancaster, Lancaster to Maryland line, Harrisburg to Gettysburg, Wellsboro to Towanda, Hollidaysburg to Clearfield, Bedford to Ebensburg, Tunkhannock to New York line, Washington to Greensburg, Coudersport to New York line, Pittsburgh to New Castle, Franklin to Mercer, Warren to Mercer, New Castle to Meadville, Reading to Allentown, Allentown to Easton and Allentown to Mauch Chunk.

Maryland Chief Asks Change in Law

BALTIMORE, MD., Dec. 26—Governor Austin L. Crothers, the retiring chief executive of Maryland, in his message to the Legislature, recommends that the office of Motor Vehicle Commissioner be abolished by the state and that the enforcement of the law be placed in the hands of the state roads commission. In discussing the motor vehicle law and the changes he suggests, Governor Crothers said:

"This law, passed by the last legislature for securing state revenue from the use of motor cars and to regulate and make safer their travel upon the public roads, has been a success. The revenue collected by this department in licenses issued has amounted to $103,000. I believe in 5 years this will reach $300,000, which will go to the maintenance and building of state roads.

"The motor car is here to stay. Could we not manufacture them to a greater extent within our own state and keep the money at home?"

Wisconsin to Build 645 Miles of Road

MADISON, WIS., Dec. 26—The Wisconsin Highway Commission, created by an act of the last legislature appropriating $350,000 annually for an indefinite period of years for state aid for highway construction, has just announced that $1,250,000 will be expended in this state during 1912 for highway improvement as the result of the granting of state aid.

This total has surprised even the most enthusiastic supporters of state aid and proves that the state aid law is being received in a most gratifying manner. The details of the expenditures reported by the commission are as follows: Stone roads, 220 miles; gravel roads, 150 miles; shale road, 25 miles; dirt road, 250 miles, a total of 645 miles. In addition there will be constructed under this act 140 bridges to cost $150,000 and divided among 123 townships. Never before in the history of Wisconsin has there been so great a proposed expenditure for highway work.

Entries for the French Grand Prix

UNDER date of December 9 there had been entered for the Grand Prix and Coupe de l'Auto races—to take place jointly in June, 1912, if 30 entries are booked before December 30, 6 o'clock evening—the following cars: 4 Lorraine Dietrich, 4 Gregoire, 4 Lion-Peugeot, 2 Peugeot and 4 Darracq. The following were mentioned as sure to be booked immediately the nominations having been forwarded: 4 Sizaire-Naudin, 3 Alcyon and of English cars 3 Calthorpe and 3 Sunbeam. "This is without counting those which we shall soon name," adds Charles Faroux, the editor of *La Vie Automobile* and original organizer of the Coupe de l'Auto, writing in *L'Auto,* the daily automobile and sporting journal of Paris. This journal is also in receipt of a communication from the Mathis firm of Alsace-Lorraine announcing that this manufacturer has refused to join the German boycott of the two races, and in another paragraph it is intimated that the real reason for the unfriendly action of the other German firms is to be sought in the fact that one of the foremost among them recently lost its chief engineer, who emigrated to a neighboring country, taking with him all his assistant designers, and the firm, finding itself unable to compete with much hope of winning, engineered a general German boycott to save its own prestige.

Quakers Ask for Fairmount Date

PHILADELPHIA, Dec. 26—Notwithstanding the fact that Dr. J. William White, a member of the Fairmount Park Commission, has taken preliminary steps to halt the running of the Fairmount Park road race, and that the holding of the 1911 event created a deficit in the organization's treasury, application for sanction has been made and a date has been assigned to the Quaker City Motor Club by the American Automobile Association for the 1912 race for Saturday, October 5.

In addition to the admission of about 30 new members at a meeting held this week in the clubrooms, Hotel Walton, plans were made for an active winter, a feature of which will be a series of lectures on automobile topics—engines, tires, radiators, etc. The first of these talks will be given in the middle of January, when Charles Y. Knight, the inventor of the engine bearing his name, will deliver a lecture on engines.

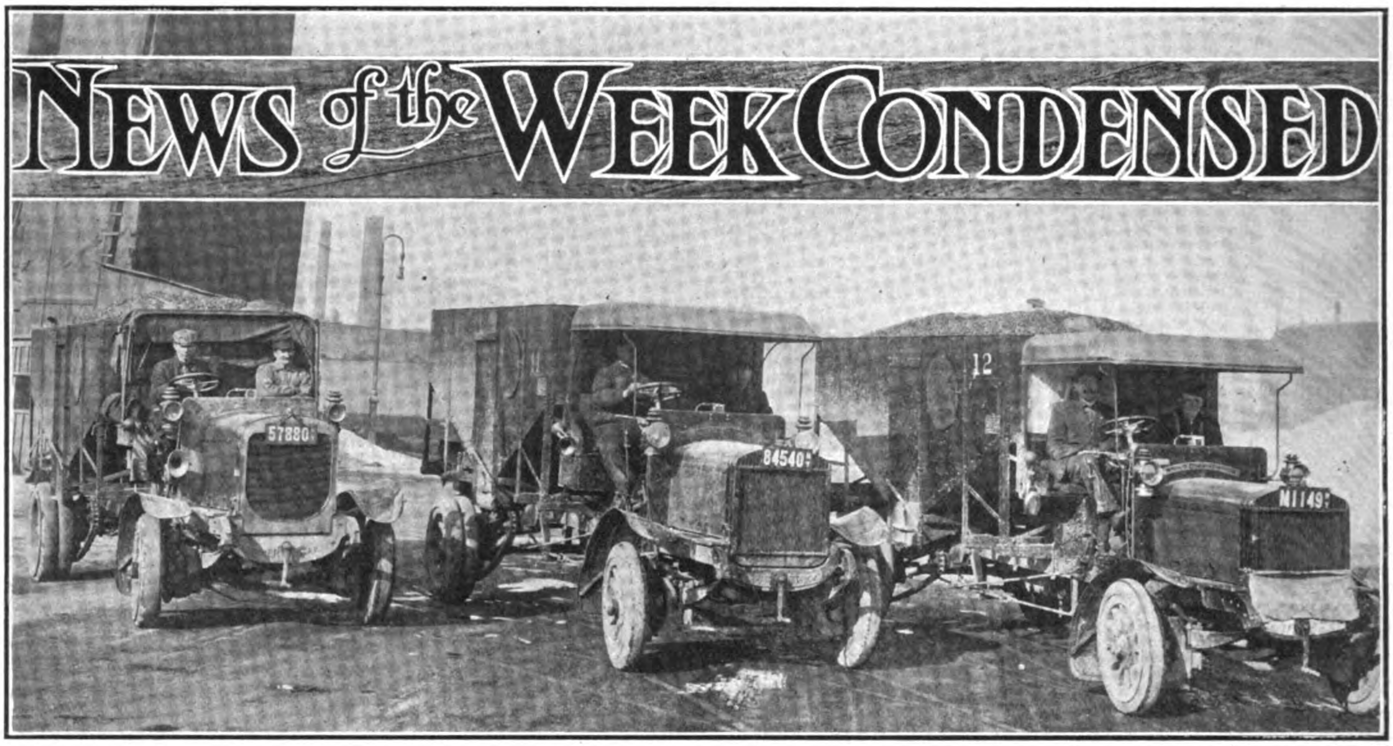
Race Promoters Ask for Big Dates

Applications for racing dates covering six of the great automobile road racing and speedway features for 1912 have been filed with the Contest Board of the A. A. A. The Elgin national stock car races will be held August 30-31, according to the request on file. This will almost certainly be granted by the board.

The Quaker City Motor Club has also applied for the date of October 5 for holding the annual Fairmount Park road race and it is understood that there will be no trouble in securing that date for the event. At Bakersfield, Cal., a road race will be held, probably February 22, and such reservation is expected to be made this week upon receipt of formal application.

The Indianapolis Speedway has applied as usual for race dates on Memorial, Independence and Labor days. The latter date, the first Monday in September, comes pretty close to the tentative dates for the Elgin stock car meeting and some sort of an adjustment is expected to do away with the difficulty.

Los Angeles automobilists have inquired of the A. A. A. whether a sanction will be required for the race meet now planned as a benefit for Hanshue, injured during the desert race.



Fleet of Commer trucks now in use by H. L. Herbert & Company, coal dealers, of New York City

NEW YORK CITY.—The firm of H. L. Herbert & Company is one of the numerous coal-dealing concerns which are changing from the old system of delivery with horses to the motor truck system. The company has a fleet of eight Commer trucks in service and is finding the new way much cheaper and more efficient than the old.

DENVER, COL.—J. C. Fry, J. W. Ebert and R. M. Robertson have joined the salesforce of the local branch of the Metzger Motor Car Company.

SYRACUSE, N. Y. — The Hupmobile agency here has been taken over by Frank P. Anderson, who handles the Alco in this territory. C. H. Marshall was formerly the Hupmobile agent.

ATLANTA, GA.—The Atlanta Automobile and Accessory Dealers' Association will hold an automobile show in the Auditorium-Armory from February 10 to 17. Homer C. George is manager.

FLINT, MICH.—F. W. A. Vesper has resigned his position as manager of the Texas Buick Company of Dallas, Tex., to become assistant general sales manager of the Buick Motor Company of this city.

DENVER, COL.—The R. C. Hupp Company has appointed the following agents in this territory: Browning Bros., Ogden, Utah; R. C. Tarrant, Sheridan, Wyo.; P. W. Pitman, Las Animas, Col., and Ideal Motor Company, Pueblo, Col.

SYRACUSE, N. Y.—A new automobile company is shortly to be incorporated in this city to be known as the E. B. Sabine Company. The Bissell garage will be the temporary home of the company, which will handle the Cutting car.

CHICAGO, ILL.—The American Electric Company, State street, Chicago, has opened a permanent downtown sales and show room at 1254 Michigan Boulevard in the New Southern Hotel building. This has been designated the Samson Horn Store.

NEW YORK CITY.—The Philadelphia Storage Battery Company has opened a new New York office in the American building, Broadway and Columbus Circle, in order to facilitate the handling of its increasing business in electric vehicle batteries and other types of batteries used in the automobile trade.

ATLANTA, GA.—A state association of automobilists will be formed at a meeting which will be held in Atlanta, January 2. G. W. Hanson, chairman of the meeting and the originator of the scheme, appointed Walter P. Andrews as chairman of a committee to draw up a constitution and by-laws. The clubs of Savannah, Macon, Augusta, Griffin, Americus, Albany and Rome will affiliate with the state body.

DENVER, COL.—The Overland Auto Company, Western distributor for the Willys-Overland Company, has appointed the following agents in their territory: Canyon City Auto Company, Canyon City, Col.; Paul Auto Company, Colorado Springs, Col.; Tyler Auto Company, Pueblo, Col.; R. K. Young, Salida, Col.; W. Whalen, East Las Vegas, N. Mex.; Monte Vista Motor Car Company, Monte Vista, Col.; F. W. Roedel, Cheyenne, Wyo.; J. H. Walker & Son, Santa Fé, N. Mex., and Forest Lumber Company, Fort Collins, Col.

DETROIT, MICH.—The new Miller carbureter, which is now manufactured in Los Angeles, Cal., will now be manufactured in the east as soon as the factory is completed in this city. The company has secured E. J. Edmond, of 1783 Broadway, New York City, to handle the carbureter in the Eastern states.

ANDERSON, IND.—William O. Kennington, of London, England, has accepted the position of assistant chief engineer with the Remy Electric Company of this city. Mr. Kennington, while a young man, has had a long experience in the electrical engineering profession.

EVANSVILLE, IND.—The Columbia Taxicab Company has been organized here to conduct a taxicab and baggage delivery service. The company has been incorporated with an authorized capitalization of $10,000, the principal stockholders and directors being E. C. Kinkle, Walter Wheeler, A. C. Mathias and H. E. Hulsman.

FINDLAY, O.—The Main Garage, on North Main street, has been sold by its owner, Earl Myers, to George Koogle. The business was established several years ago.

DES MOINES, IA.—Twenty-five Overland agents from Central met in Des Moines Monday as the guests of the Riddell Auto Company, local agent for the company. T. C. Whitcomb, sales manager, was present.

OWOSSO, MICH.—A deal has been closed by which E. A. Eddy, Sr., and his son, both of Bay City, become owners of the equipment of the defunct Owosso Motor Company. They expect to manufacture the car in Bay City. The Owosso company was made up of local business men.

DENVER, COL.—The Boss Rubber Company has added the Kelly-Springfield tire to its line.

COLUMBUS, O.—The contract has been awarded for a large garage at Sixth and Kaiser streets for the George W. Bobb Company.

KANSAS CITY, MO.—The Truffault-Hartford Company has opened a branch in this city at 1524 Grand avenue. Henry Romer is in charge.

CLEVELAND, O.—The Brooks - Norton Motor Sales Company, of 1927 Euclid avenue, has taken the agency for the Ohio electric and the Modern truck.

SPRINGFIELD, O.—The Springfield Tire & Rubber Company has increased its capital from $50,000 to $150,000 and will make additions to its factory next year.

ATLANTA, GA.—The Premier Motor Manufacturing Company will open a southern service department in Atlanta about January 15. J. E. Levi will be in charge.

PHILADELPHIA.—W. R. Darrah, E. G. Brown and Robert Yerger have recently become affiliated with the Paxton-Crumley Auto Company, of 660 North Broad street.

COLUMBUS, O.—E. H. Wilson and J. C. Langley, proprietors of the Enterprise Garage at 241 West Fourth avenue, have taken the central Ohio agency for the Star starter.

LOUISVILLE, KY.—The Automobile Club of Louisville has got out a club paper entitled *Toots*. E. J. Strauss is managing editor and Colonel W. B. Haldeman is editor.

MANCHESTER, N. H.—The C. R. Sawyer Company, of this city, has closed with the Velie Boston branch for the sale of Velie pleasure cars and trucks in this section of New Hampshire.

PHILADELPHIA—H. A. Jenks has joined the sales force of the Philadelphia Locomobile Company. Mr. Jenks was formerly connected with the Philadelphia branch of the Stoddard-Dayton.

ATLANTA, GA.—Henry Nyberg, of the Nyberg Automobile works, of Anderson, Ind., and Chicago, recently visited Atlanta and it is reported that he plans to open an automobile factory here.

UTICA, N. Y.—The Millers Motor Company, 109 Arcade building, with garage at 7 Jewett place, has taken the agency for the Metz automobile made by Charles Metz, a former Utican.

DETROIT, MICH.—C. A. Hamilton, who has been vice-president and general manager of the Wisconsin Engine Company, has resigned his position to take an interest in the Lavigne Gear Company

COLUMBUS, O.—The Adamson Automobile Company, of 5 West Mound street, has taken the distributing agency for the Paige-Detroit for Franklin, Delaware, Madison, Pickaway and Union counties.

PROVIDENCE, R. I.—W. P. Kennedy has been appointed head of the transportation cost bureau which has been established by the American Locomotive Company in connection with the motor truck department.

CUMBERLAND, MD.—The partnership of Blays & Cochrane, trading as the Queen City Garage, has ben changed to the Queen City Garage, Inc., B. H. Blays having disposed of his interest to the latter corporation, of which Alpheos B. Cochrane is the president.

ANDERSON, IND.—Mr. J. L. Elwood has affiliated with the service department of the Remy Electric Company, with headquarters at the factory in this city. Mr. Elwood was lately engineer of the Sam'l L. Moore Sons' Company, of New York City and Elizabeth, N. J.

KANSAS CITY, MO.—The Missouri Valley Auto Company has been placed in the hands of a receiver. The company handled the White car and was one of the oldest firms in the city. The White Motors Company, a newly organized concern, will handle the White at 1616 Grand avenue.

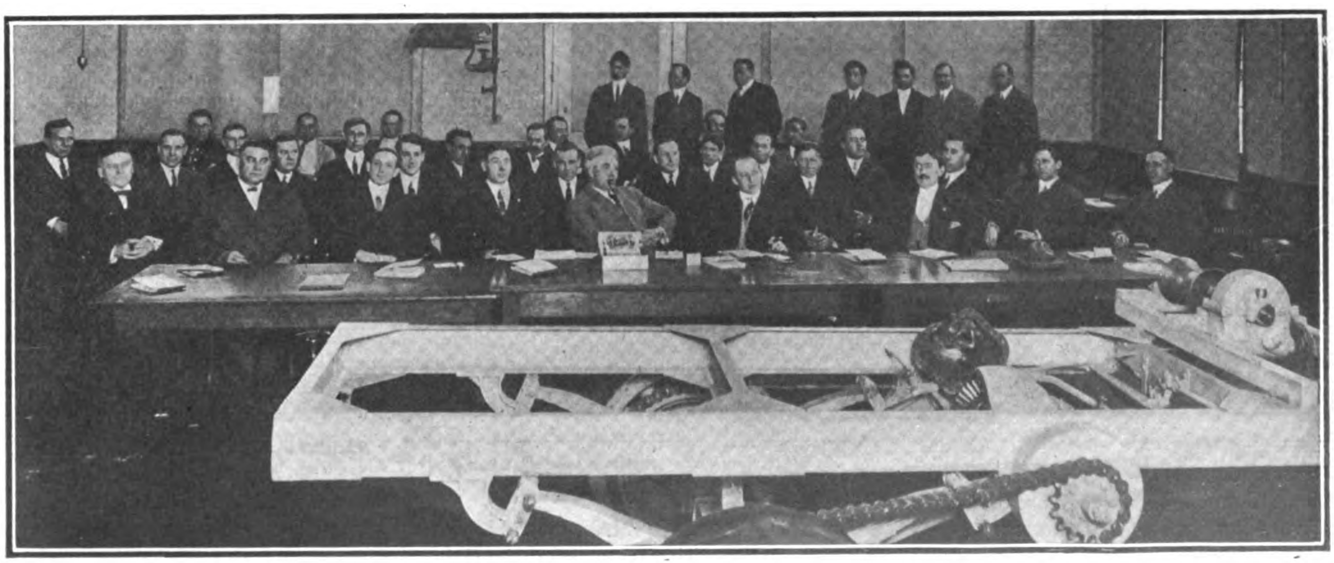
BOSTON, MASS.—The J. W. Bowman Co., distributors of the Stevens-Duryea cars, is to have one of the largest and most completely equipped service stations possessed by any automobile dealer in New England. It is being erected on Vassar street, Cambridge, and is a one-story structure with 30,000 square feet of available floor space.

DENVER, COL.—The Western Marion Motor Company, which handles the Abbott-Detroit and the Marion for this territory, will begin the new year under the name of the Western Motor Car Company. This firm was also recently made the agent for the American self-starting device.

NEWCASTLE, IND.—W. F. Byrket, who has been connected with the United Motor Company in various capacities for several years, has been appointed manager of the United Motor Indianapolis Company. He succeeds Thomas L. Marshall, who will become assistant superintendent of the company's central sales district.

CLEVELAND, O.—A reorganization of the Motor Tire & Repair Company at 6506 Euclid avenue has been effected. E. C. Anderson continues as the active head of the company. Those associated with him are: H. L. Lance, C. B. Haycox and C. A. Stimson. The company will continue to handle the Republic car.

SEATTLE, WASH.—J. T. Geena & Company, Packard agents are erecting a new building on the southeast corner of Pine street and Twelfth avenue. When completed the Packard building will be one of the most complete, modern automobile salesroom and garage buildings on the Pacific Coast. It will have about 40,000 square feet of floor space.



First annual convention of the Speedwell truck agents, at the factory in Dayton, Ohio

Showing the average weekly output of Knox trucks for 1911

WAPAKONETA, O.—The Hauss & Bitler Company has taken the 1912 agency for the Stoddard-Dayton in this territory.

LOS ANGELES, CAL.—Curtiss-Shea-Cox, Inc., are planning to erect a plant in this city for the manufacture of automobiles.

COLUMBUS, O.—Messrs. Sperry and Hoover have taken over the repair business of the Adamson Automobile Company at 35 West Mound street.

BOSTON, MASS.—The Henley-Kimball Company, agent for the Hudson, is having a service station constructed in Cambridge.

SCRANTON, PA.—Application for a patent for a flexible steel tire for automobiles has been made to the government by John Dougherty, of 1003 Prospect avenue.

PONTIAC, MICH.—Pontiac Power Company, which recently acquired the Rapid Motor Vehicle Company's power plant, has been authorized to expend $36,000 in improvements.

SPRINGFIELD, ORE.—A company has been organized here by D. Tower for the manufacture of automobile trucks. Local capital has been subscribed and a small factory has been started.

KANSAS CITY, MO.—The Hartford Suspension Company, manufacturer of the Traffault-Hartford shock absorber, has opened a branch factory at 1542 Grand avenue. Harry Roemer is manager.

BOSTON, MASS.—Roscoe B. Davis, for several years with the Maxwell branch in Boston and later with other agencies, has joined the sales force of the Empire Motar Car Company, agent for the Empire and Stutz cars.

NEW HAVEN, CONN.—Knight's Garage, Inc., of this city, has closed with Harold D. Bornstein of the Velie Boston branch for the sale of Velie pleasure and commercial cars in New Haven and New London counties.

DETROIT, MICH.—Henry Goodman, eastern traveling salesman for the Flanders Manufacturing Company, has resigned his position and accepted a position with the Grinnell Electric Car Company, of Detroit, as general sales manager.

COLUMBUS, O.—The net receipts of the Ohio State Automobile Department for the year ending December 15, 1911, were $156,680.65. This amount goes to the fund for the building and maintenance of good roads in the Buckeye State.

KENTON, O.—William Willeke of this city is the inventor of a device to regulate gas tanks on automobiles, which is claimed to be the best of its kind ever conceived. An automobile manufacturing concern is negotiating for the purchase of the device.

DETROIT, MICH.—J. H. Newmark, for four years advertising manager of the Oakland Motor Car Company, of Pontiac, Mich., has resigned that position, having been advanced by the General Motors Company to the advertising department of the parent organization in this city.

DENVER, COL.—The handsome two-story building erected by Tom Botterill at the corner of Thirteenth and Broadway is now occupied by the owner, who handles the Pierce-Arrow, the Hudson and the Columbus, and by the Colorado Automobile Company, local representative of the Cadillac.

DETROIT, MICH.—Automobile Designing Engineers' Society, an organization intended to promote the art of designing automobile motors, motor cars and tools, was formed recently at a meeting held in College of Automobile Engineering. Regular meetings will be held at the college, 287 Woodward avenue.

LIMA, O.—Two storerooms located on the east side of South Elizabeth street between Market street and Spring street, have been leased for automobile salesrooms. Henry S. Thurston will occupy one of the rooms as an agent for the Jackson line and G. W. Griffith the other as agent for the Krit.

CANTON, O.—The directors of the Stark Auto Company of this city, which was incorporated recently with a capital of $20,000, have elected W. H. Burgener president; T. E. Huthe, general manager; Samuel Heaney, shop manager; George Shaffer, vice-president and George F. Frones, secretary and treasurer.

MILWAUKEE, WIS. — Among the new agencies in Milwaukee recently contracted for are the following: Union 25, Marx Bros.; Staver-Chicago, Henry Walter; Nyberg, Tuschan Bros.; King, Eustace Bros.; Arthur F. Tiegs, Colby; Gas Power Engineering Company, Premier and Moline; Elmore, Edwin B. Leverenz.

BOSTON, MASS.—W. H. Vinal has returned from a trip to York, Pa., where he closed a deal for the agency for Pullman cars in Eastern Massachusetts. He will at once assume the management of the Boston Motor Company, which handles the S. G. V. and the De Dion.

SPRINGFIELD, MASS.—The phenomenal growth of the truck industry in the United States is readily appreciated when one realizes that the line of trucks shown in the accompanying illustration represents only one week's output of the Knox Automobile Company of this city.

ATHENS, O.—The Ohio-West Virginia Sales Company of this city has taken the agency in southeastern Ohio for the Cutting touring cars and the Garford trucks. F. E. Shattuck is manager of the concern.

COLUMBUS, O.—The Adamson Automobile Company of 35 West Mound street, has contracted to distribute the Paige-Detroit line for 1912 in Franklin, Delaware, Madison, Pickaway and Union counties.

MILWAUKEE, WIS.—C. E. Mills has joined the Hickman-Lauson-Diener Company, state agents for the Ford.

CINCINNATI, O.—The Payne Motor Car Company, distributing the Hudson, has removed to 122-124 Seventh avenue.

PENDLETON, ORE.—A new garage and repair shop has been opened here under the title of the Oregon Motor Company.

LANCASTER, O.—The Adamson Automobile Company of Columbus, Ohio, has contracted with J. Elden Lawrence to handle the Jackson in Fairfield county.

COLUMBUS, O.—Kimmel Brothers, 215 North Fourth street, will handle the Cole line of automobiles in connection with the Speedwell.

DES MOINES, IA.—W. C. Haywood, Secretary of State for Iowa, has issued a pamplet containing a synopsis of the new automobile laws passed by the last legislature.

BOSTON, MASS.—H. E. Leefe, formerly with the local branch of the Selden, is the latest addition to the salesforce of the Connell & McCone Company, agents here for the Overland.

MILWAUKEE, WIS. — The Milwaukee board of public works has purchased a Mitchell roadster for the use of the consolidated police and fire alarm telegraph system of the city.

NEENAH, WIS.—William C. Nash has been elected president of the Neenah Brass Works. Henry Horkman is vice-president and general manager and David Horkman is secretary and treasurer.

SPRINGFIELD, MASS.—The United Motors Company secured an option on a large tract of land in the center of the city as a site for a large building which will be utilized as a salesroom and a garage. It will cost $150,000.

SYRACUSE, N. Y.—W. R. Shaw has purchased the entire stock held by the Strait estate in the automobile firm of Strait & Shaw and assumes sole ownership January 1. He will continue to conduct the business at No. 225 West Genesee street.

SAGINAW, MICH.—By the purchase of the stock of Charles E. Duryea, former president of the Duryea Auto Company, by C. C. Brooks, the legal difficulties in which three injunctions were issued, has been ended. Frank C. Palmerton has been elected president and general manager, which offices Mr. Duryea held.

COLUMBUS, O.—The Broadway Motor Car Company, 842 and 844 West Broad street, is the name of a firm formed by J. F. Morgan and H. F. Kaiser to handle the Paige-Detroit in Franklin county for 1912 and to do a general garage and repair business. The concern has a new building.

BOSTON, MASS.—F. R. Parker, who formerly handled the Elmore in this territory, has signed a contract with the United States Motors Company to distribute Brush cars throughout New England. He has also taken on the Staver-Chicago line for Maine, New Hampshire, Vermont and Massachusetts.

DETROIT, MICH.—The Wolverine Automobile club has made arrangements with the Michigan Central Railroad to run a special to the New York show. The train, consisting of standard sleepers, a compartment car and a buffet library car, will leave at 3:30 o'clock Friday afternoon, arriving in New York at 9 o'clock Saturday morning. A large delegation is arranging to go from the club.

WINNIPEG, MAN.—At the annual meeting and banquet of the Winnipeg Motor Trades' Association, the following were re-elected by acclamation as officers for 1912: president, F. E. H. Lake, Russell Motor Car Company; vice-president, W. C. Power, McLaughlin Carriage Company; treasurer, G. A. Malcolmson, Ford Motor Company; secretary, A. C. Emmett, automobile editor of *Free Press.*

Automobile Incorporations

AUTOMOBILES AND PARTS

AUSTIN, TEX.—Regal Motor Car Co.; capital, $1,000,000; to sell automobiles and parts.

BOSTON, MASS.—Orin Ray, Inc.: capital, $50,000; to deal in automobiles. Incorporators: O. Ray, W. N. Tuller, H. O. Ray.

BOSTON, MASS.—Stratton Automobile Co.; capital, $5,000; to deal in automobiles. Incorporators: H. C. Stratton, J. S. Stratton, G. W. Stratton.

BOSTON, MASS.—Rex Motor Co.; capital, $1,000; to deal in automobiles. Incorporators: H. C. Stetson, H. W. True, C. F. Moore.

BROOKLYN, N. Y.—Ormond Motor Car Co.; capital, $100,000; to deal in automobiles. Incorporators: G. H. Howell, R. McKeller, T. Downs.

BUFFALO, N. Y.—Carroll Tire Co.; capital, $20,000; to manufacture rubber tires. Incorporators: John Gregson, George Cunliffe, J. E. Gregson.

CHICAGO, ILL.—Swanson Motor Car Co.; capital, $50,000; to deal in automobiles, trucks, etc. Incorporators: C. E. Swanson, E. E. Challenger, M. E. Gallion.

CHICAGO, ILL.—La Salle Auto Oil Co.; capital, $25,000; to manufacture automobile motors and accessories. Incorporators: W. R. Watson, G. W. Curtis, L. E. Powell.

CHICAGO, ILL.—Perfection Auto Tire Co.; capital, $15,000; to manufacture automobile parts and appliances. Incorporators: R. E. Cruzen, G. R. Cruzen, D. C. Hutchins.

CHICAGO. ILL.—Mechanical Appliance Co.; capital, $200,000; to deal in motors and generators. Incorporators: W. A. Feeney, Frank Venning.

CLIO, S. C.—Hubbard Motor Car Co.; capital, $3,000; to deal in automobiles. Incorporators: J. L. Hubbard and others.

DOVER, DEL.—Motor Owners' Tire Co.; capital, $300,000; to manufacture and deal in automobile tires and other fixtures.

DOVER, DEL.—Samson Tire & Rubber Co.; capital, $100,000; to manufacture rubber tires for automobiles.

HATTIESBURG, MISS.—Southern Automobile & Machine Co.; capital, $50,000; to deal in automobiles. Incorporator: R. R. Boykin.

INDIANAPOLIS, IND.—Empire Gear Co.; capital, $20,000; to manufacture motors, transmissions and other automobile parts. Incorporators: Frank S. Clark and Charles H. Hurd.

KANSAS CITY, KAN.—Kansas City Auburn Co.; capital, $10,000; to deal in motor trucks. Incorporators: Charles Eckhart, F. E. Eckhart, Morris Eckhart.

MILWAUKEE, WIS.—Automatic Motor Devices Co.; capital, $1,000; to sell automatic automobile accessories. Incorporators: H. B. Webb, C. J. Dellfield, J. T. Drought.

NEWARK, DEL.—New Garage & Electric Co.; capital, $5,000; to manufacture and deal in automobiles. Incorporators: G. Fader, E. G. Fader, A. F. Fader.

NEW YORK CITY.—Detmar Auto Sales Co.; capital, $20,000; to manufacture and deal in vehicles, engines and machinery. Incorporators: John McLaren, B. F. Knowlton, Edward C. Underlied.

OMAHA, NEB.—Omaha Auburn Auto Co.; capital, $10,000; to deal in automobiles. Incorporators: Charles Eckhart, Morris Eckhart.

SALEM, N. J.—Blue Ribbon Automobile Service Co.; capital, $25,000; to rent automobiles and deal in automobile supplies. Incorporators: G. B. Sheppard, J. D. Sharman, F. E. Hurley.

SPRINGFIELD, MASS.—Morse-Readio Auto Co.; capital, $150,000; to manufacture and deal in automobiles. Incorporators: G. U. Readio, G. E. Morse, E. M. White.

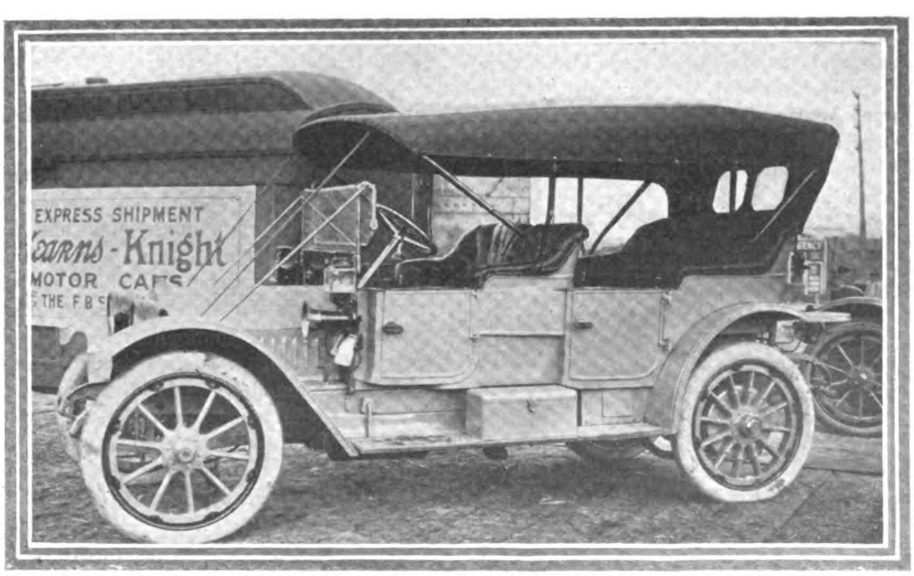
WILMINGTON, DEL.—American Tire & Rubber Co.; capital, $1,500,000; to manufacture rubber tires.

AUTOMOBILES, GARAGES, ETC.

SPRINGFIELD, MASS.—New England Auto Owners' Association; to obtain supplies at a lower price. Incorporators: R. A. McKee, A. W. Warren, M. T. Workman.

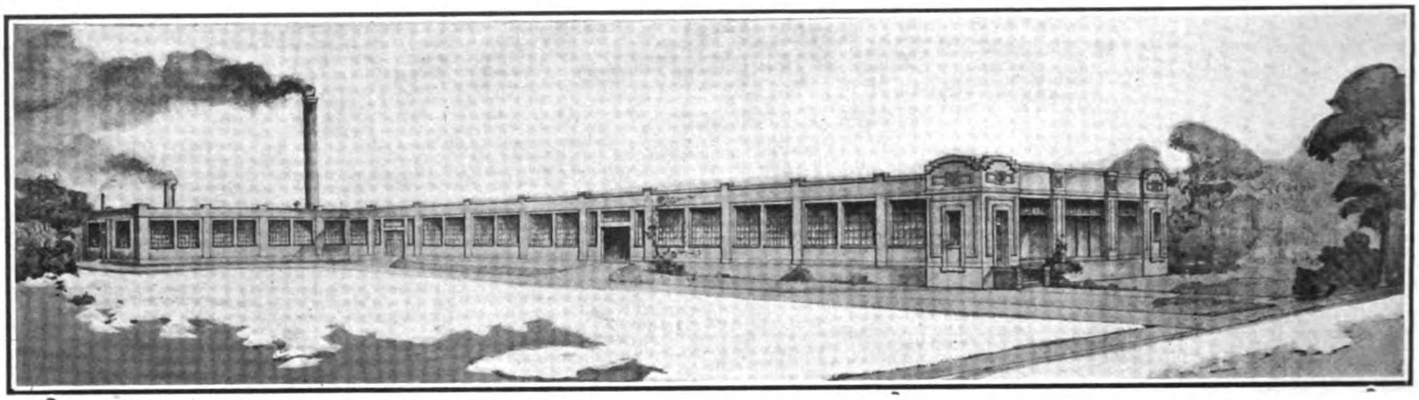
SPRINGFIELD, OHIO.—Compressed Air Machine Co.; capital, $100,000. Incorporators: Lewis C. Kiser and others.

TOLEDO, OHIO.—Toledo Auto Delivery Service; capital, $10,000; to conduct a transportation business. Incorporators: Chas. K. Friedman, Joseph Straus, Kittie Alexander, Joseph Alexander, Morris Tobias.



Unloading shipment of Stearns-Knight cars at San Francisco

OF INTEREST to the INDUSTRY



New plant of the Republic Motor Car Company at Hamilton, Ontario.

HAMILTON, O.—The new plant of the Republic Motor Car Company is of heavy type mill construction, with exceptionally large window space. The window frames are all steel and the entire building is absolutely fire-proof. It will be ready for occupancy January 15.

CHICAGO, ILL.—The Chicago Commercial Car Company is building a new factory on the North Side on the railroad and Evanston avenue. The new building will be occupied on January 1.

DALLAS, TEX.—The Firestone Tire & Rubber Company will open a direct factory branch in this city January 1. It will be located at 1521 Commerce street and will be under the management of Mr. P. B. Talbott.

CUDAHY, WIS.—The new office building of the Federal Rubber Manufacturing Co. on Layton avenue will be ready for occupancy about January 1. It is two stories high, of red press-brick construction and a model structure of its kind.

BOSTON, MASS.—Harry Israel, general sales manager of the O'Neil Tire Protector Sales Company of Cleveland, O., and James Watters, who is the New England representative of the firm, have been in Boston seeking a location to open a branch here.

BROOKLYN, N. Y.—As has been its custom for a number of years, the Moller & Schumann Company had its selling force at the factory on Monday, Tuesday and Wednesday of last week for the usual annual conference. The meeting was probably the most successful ever held.

GRAND FORKS, N. D.—A new Ford branch has just been opened under the name of the Ford Automobile Company. The new house will be both retail and wholesale and will have charge of the distribution of Ford cars in contiguous Minnesota and North Dakota territory.

DALLAS, TEX.—Following the policy of establishing branch service stations in all parts of the country, the Remy Electric Company of Anderson, Ind., has opened a service station and supply house in Dallas, Tex. The establishment will be known as the Remy Service Station and will be in charge of Mr. M. A. Price.

BATAVIA, N. Y.—The Batavia Rubber Co. has increased its capital stock from $70,000 to $500,000. Options have been secured on several large tracts of land adjacent to the factory. The new capital will be used in the extension of the company's plant, in securing additional machinery and equipment and in other ways tending toward a largely increased output. The company makes a specialty of its patented Security non-skid tire. It has added a solid tire to its line.

MASON CITY, IA.—The controlling interest of the Colby Motor Co., has changed hands. New officers were elected as follows: President, J. E. Burmeister; vice-president, Wm. C. Colby; treasurer, H. S. Murphy; secretary, W. N. Smith; general manager, D. W. Henry. Under the new management it is expected that the output of the factory will be increased and that the line of trucks will rapidly be completed and put on the market.

KEWAUNEE, WIS.—O. O. Storle, inventor of a number of mechanical appliances, such as valves, couplings, etc., has just been granted patents on a new type of gasoline engine or motor, which he will manufacture at Kewaunee. The feature of the engine is the employment of two piston heads and rods in each cylinder, which is claimed to make the engine capable of doing twice the work of the ordinary engine at the same expense for fuel. The expense of producing the engine is said to be practically equal to that of the ordinary engine.

INDIANAPOLIS, IND.—The Presto-O-Lite Company of this city now has agents and branches in the Hawaiian, Philippine and West Indian Islands as well as in Canada, Mexico, Germany and Australia. These branches help to solve the shipping problem, as all steamship bills-of-lading specify that all tanks on cars being shipped shall be empty.

CLEVELAND, O.—A $350,000 corporation has been organized by the Grant Lees Machine & Tool Company and the Stuyvesant Motor Car Company to manufacture the Stuyvesant automobile or rebuilt Gaeth car. The new corporation will take the name of the Stuyvesant Motor Car Company. The entire plant of the Stuyvesant Motor Car Company, now located on the West Side, will be moved to the East End within sixty days.

TACOMA, WASH.—Uniform prices of supplies and work are to be fixed by Tacoma automobile men, who met recently at the Chamber of Commerce and organized the Tacoma Automobile Dealers' Association, with Edwin C. Chambers as president; T. W. Little, vice-president; Harry W. Doherty, secretary and treasurer and C. L. Ross, W. W. King and E. C. Reynolds trustees. Committees were appointed to work with the association in the regulation and forming of uniform rates on supplies and garage work.

BRYAN, O.—Announcement is made that C. H. Bowersox, of the Bowersox Motor Sales Company, of this city, will open a sales room in Toledo for the handling of the Everitt line of cars. The sales rooms at Bryan will be retained, the company operating both places. The western half of the territory controlled by the company will be handled from Bryan, while the Toledo office will take care of the eastern territory. A manager will be placed in charge of each salesroom and Mr. Bowersox will devote his time to placing subagencies in the territory. Arrangements have been made whereby space will be secured in the building now occupied by the Gamble Motor Car Company on Madison avenue.

PATENTS GONE TO ISSUE

WIND-SHIELD—Of the flexible type with a frame adjustable in various positions.

3. The shield (Fig. 1) comprises spaced supports connected at their lower ends by a transverse member. The supports may be adjusted longitudinally through spaced guides open above and below the supports, which are provided with means for maintaining them in different positions of longitudinal adjustment. A flexible shield is connected at one end with the member above mentioned, and is free and unobstructed above the same; a roller is mounted below the member mentioned and connected with the lower part of the flexible shield, the roller being supported by the guide supports.

No. 1,012,239—to Theodore F. Bourne, Montclair, N. J. Granted, December 19, 1911; filed, December 24, 1910.

IGNITION SYSTEM FOR INTERNAL COMBUSTION ENGINES—In which the spark plug terminals serve as contact makers for the ignition circuit.

1. In this system (Fig. 2) a number of cylinders with a spark plug in each are combined with a number of separate insulated conductors contained in a tube passing closely by the spark plugs and having an opening opposite each spark plug. At each opening a holder is secured to the tube, the holder containing a terminal member which makes contact with one of the conductors. Pivoted switch arms supported by the holders and in position to make contact with the spark plugs, are thereby caused to close a circuit between them and the conductor terminals.

No. 1,011,977—to Allen Loomis, Detroit, Mich., assignor to the Packard Motor Car Co., Detroit, Mich. Granted December 19, 1911; filed December 27, 1907.

TURNBUCKLE—Device containing arms ending in sleeves.

The turnbuckle yoke (Fig. 3) referred to in this patent comprises an integral casting having spaced arms terminating in sleeves joining their ends. The sleeves have registering openings, and the arms have also cross bars spaced inwardly from the sleeves and provided with openings registering with the sleeve openings.

No. 1,012,008—to William F. Post, Asheville, N. C. Granted December 19, 1911; filed November 14, 1910.

CRANKING DEVICE—Crank for internal combustion motor containing provision against back kicks.

4. This patent refers to a device comprising a starting shaft which may be connected with the crankshaft of an engine and which is provided with a laterally projecting coupling pin. On the starting shaft a crank is loosely mounted and is provided with a sloping driving shoulder adapted to engage the pin. A ratchet mechanism is interposed between the crank and a stationary part, which mechanism permits of forward turning movement of the crank, but which prevents backward turning movement thereof. The ratchet mechanism comprises a disc mounted on a stationary part and provided with an annular row of ratchet teeth, and a spring-pressed pawl which is pivoted on the hub of the crank and engages the teeth of the ratchet.

No. 1,012,116—William Van Scoter, Buffalo, N. Y., assignor of one-fourth to William J. Hayes, Buffalo, N. Y. Granted December 19, 1911; filed February 13, 1911.

FORCE-FEED CARBURETER—A reciprocating member working in alignment with the supply pipe pumps the fuel into the carbureter proper.

1. The carbureter protected by this patent comprises a charge supply tube on which a carbureter casing is arranged. Through the casing extends an oil pipe which has inlet and discharge valves, and a reciprocating member aligned with the oil pipe is connected to a pipe for admitting pressure to it by a hollow flexible connection. A second hollow and flexible connection is arranged between the oil conducting pipe and the reciprocating member which is stayed between the flexible connections by a fixed support. The member is provided with a flange in the path of which a sleeve is adjustably mounted in the fixed support.

No. 1,011,931—to Charles W. Farquharson, Chicago, Ill. Granted December 19, 1911; filed October 13, 1910.

TIRE-INFLATER—A tire pump which is driven by the engine to compress air for filling the tires.

1. This patent covers an apparatus consisting of a frame or casing and a driven mechanism carried by same and taking power from a driving member. This engages a driven member connected with the mechanism proper. Means are adjustably supported with respect to the driven member and engaging with the driving member at a point sufficiently removed from the point of engagement between driving and driven member, the means mentioned balancing partially the forces which tend to displace the driven member and permitting the latter to be held, by hand, in engagement with the driving member.

No. 1,012,098—to Enoch Rector, New York, N. Y. Granted December 19, 1911; filed August 3, 1910.

BACKFIRE EXTINGUISHING DEVICE—In which a baffle plate is used to resist the flame finding its way into the gas pipe.

2. This device comprises the combination of a supply pipe having a conically enlarged portion with an imperforate cone-shaped baffle member contained in the enlargement mentioned, the base of the baffle member being substantially flat and directed toward the point of consumption. A space is provided all around the baffle, the sectional area of this space being not less than that of the supply pipe.

No. 1,011,961—to Alexander Constantine Ionides, Jr., London, England. Granted December 19, 1911; filed December 5, 1910.

Newest Ideas Among the Accessories

Dover Gasoline Vessels

IN Fig. 1 a special form of gasoline funnel, made by the Dover Stamping & Mfg. Company, of Cambridge, Mass., is shown. The funnel proper is attached to a crank-shaped filler pipe, which fits into the filler hole of any gasoline tank, so that the funnel may be put and left there while filling the tank with fuel. The funnel is heavily copper-plated and provided with brass strainers, as well as with a movable hoop to hold the chamois in place. A 4-quart funnel of this type has a top diameter of 9 3-4 inches, while the diameter of the outlet pipe is 7-8 inch.

The Duplex combination vessel, Fig. 2, does the combined work of a measure and funnel. It is a cylinder which converges slightly toward the top carrying a funnel which has a spout pointing upward. The effect of this design is that when the measure is set down all the liquid runs back into the vessel instead of dripping outside. A double pouring lip is provided, one being the end of the funnel and the other attached directly to the top of the measure, providing a fast pouring measure where vessels with large opening are being filled.

The handle being on the side increases ease of operation, and on the larger sizes—this combination measure and funnel is made in five sizes—the handles have bosses. The entire device is made of extra-heavy material and the seams are soldered and guaranteed against leak. The vessel is copper-plated and laquered. The five sizes range from ½ pint to 4 quarts, all being designed along identical lines, and being furnished either in polished tin, or heavy copper-plates, or copper-plated and provided with brass strainers, to keep foreign matter from entering the tanks.

Fig. 3 shows the Dover non-evaporating gasoline measure, which is made for garage use with a capacity of 5 gallons. As may be seen from the figure, the pouring lip and filler opener in this case are one, the filler opener being in the shape of a rotary valve when in place. By turning the filler opener to a certain position, an opening in its side wall is brought to register with the pouring lip so that the fuel can be poured into the gasoline tanks without removing the filler opener of the measure. If only part of the contents of the measure is used for filling the tank, the rest is stored and kept from evaporating by so plating the filler opener in position that the interior of the tank is cut off from the surrounding air.

E-Z-2 Work Vulcanizer

The above named product of the E-Z-2 Work Steam Vulcanizer Company, of Cleveland, Ohio, is constructed along similar lines and on identical principles with the big steam vulcanizers used in tire factories. The vulcanizer proper is a hollow brass body which is partly filled with water at the factory of the makers, and being closed hermetically never needs refilling. An alcohol lamp under the brass steam boiler provides the heat for transforming the water into steam which heats the metal wall of the brass body by contact. There is no need of watching the heating water and steam, which operation is entirely automatic, since the apparatus is self-contained. One side of the brass body is curved to fit a casing, while the flat side may be applied to tubes requiring vulcanizing. A thermometer connected with the interior of the steam chamber tells the exact temperature of the metal applied to the rubber, so that with a little attention there is no chance of burning the rubber. The machine is composed of few parts, all made of highly polished, nickeled brass.

Minimax Extinguisher

Fire in the garage is the signal for cause of the destruction of a large number of high-priced machines every year and it behooves the owner of such an edifice to maintain as good a fire protection as he can possibly buy. The effects of a conflagration can never be calculated but it is true that promptness and effectiveness in the extinguishing agent is of the highest importance. These features are embodied in the Minimax, made by the Minimax Company, of Philadelphia, Pa. The acid in this device is kept in a hermetically sealed bottle and is not exposed to any other chemical until it is ready to use in a fire. A plunger is pushed in which brings the acid into contact with the soda-water, generating an acid gas which creates a pressure of 60 pounds to the square inch. The 1½ gallons of liquid will perform the work of 50 ordinarily filled water pails and in the case of fires caused by gasoline or oils will have far greater effect since water is useless on a fire of this nature. The stream from the Minimax will reach a distance of 50 feet.

Cars for Sale

A $9,000 GERMAN MERCEDES for $900
Just 10% of original cost.
5-pass. touring, recent model, fully equipped and in A1 condition mechanically.
Move quick. Need money.
Address Box 3974, care The Automobile.

A 1909 30-60 STEARNS
Toy tonneau; fully equipped.
New tires (two extra). Car rebuilt and repainted, at $1,250.
Box 3972, care The Automobile.

A BRAND NEW Car For Sale—An American Tourist, type 34, 30 h.p., 4-passenger car, to be shipped from factory by May 1st, or sooner if wanted. This car will be sold at a bargain to someone, as we wish to dispose of it at once. Apply to Carl D. Sultzman & Co., Hannibal, Mo., or make an offer.

A NEW 1912 CUTTING, model T-35.
Delivery April 1, 1912.
Fully equipped.
Will sacrifice my deposit of $250 and my reservation.
Box 3970, care The Automobile.

ATLAS RUNABOUT, 110-in. wheel base, with folding rear seat, 34x4-in. tires, in good shape; top, speedometer, etc.; car in first-class repair every way; would make good truck; price, $400, or would trade for smaller car; cars will be demonstrated one mile or 100. H. C. Lintott, Nashua, N. H.

AUTOMOBILES. Save dealer's profits, buy direct from the owners. I have all makes on my lists. Runabouts from $50 up. Touring Cars from $100 up. Get my prices before purchasing. King, Automobile Broker, Dept. A, 217 West 125th St., New York City.

All equipped and in fine running order; good tires; need money; must sell. High Point Motor Car Co., High Point, N. C.

REBUILT THOMAS CARS.

One year's work usually tells the story of the difference in construction between a high-grade, high-priced and high-powered car and those built to sell at a low first cost. The strain of gear shifting, the jar of road shocks, and the stress of brake work begin to tell on the cheaper cars. Therefore, the logical deduction is that for the man who wants a thoroughly dependable car at a moderate price the very "best buy" is a high-grade used car that has been rebuilt in the factory where it was originally made.

We have a few four and six-cylinder cars, 1908, 1909 and 1910 models, some priced as low as $1,000. These cars should not be confused with the ordinary "second-hand" proposition, as in the rebuilding all parts which show the slightest wear are replaced by new ones. If you want a car for real work, write us and we will send you special bulletins descriptive of rebuilt cars we have on hand.

For a reasonable payment we will hold one of these cars for you for early spring delivery.

Used Car Department.

E. R. Thomas Motor Car Company.

Buffalo, N. Y.

REO, 1910, 5-passenger touring car, been run less than 5000 miles; has top, speedometer, etc.; tires nearly new, lights never lighted; price $700. H. C. Lintott, Nashua, N. H.

SECOND EDITION—FULLY REVISED AND ENLARGED

THE ART OF AVIATION

By Robert W. A. Brewer

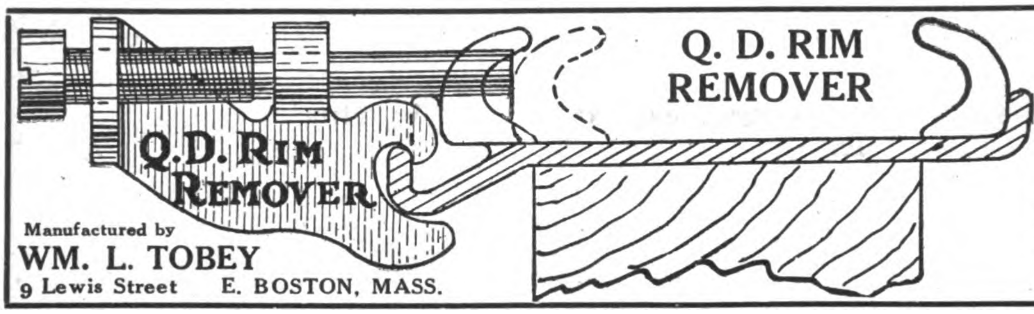
Fellow of the Society of Engineers ("Gold Medallist"), Etc.

279 pages, 6 x 9, fully illustrated and with working drawings, $3.50 net, postpaid

This new edition covers the enormous developments of the past year in every phase of aviation. It makes this book again the latest authority on the technical details of flying.

The author is an engineer and his work has been entirely from the technical side of the question. His book is a practical, working treatise. It presents working drawings for the construction of machines, describe engines and propellers in detail, and discusses the art of flying, including gliding experiments, steering, balancing and control. It will interest the general as well as the scientific public.

FOR SALE BY THE CLASS JOURNAL COMPANY, Publishers of "THE AUTOMOBILE" 231-241 West 39th Street **NEW YORK**



Q. D. RIM REMOVER

Manufactured by
WM. L. TOBEY
9 Lewis Street E. BOSTON, MASS.

Inserted at the joint of the locking ring on Universal or Fire Stone Quick Detachable Tires, will, by turning the screw, when clamp nut is removed from valve stem and stem is forced up in rim, force the clincher ring from the position in full lines over the locking ring, to the dotted position, so that the locking ring can be easily removed. This does away with the annoyance and delay usually experienced when trying to uncover the locking ring with screw driver, chisel and the usual tools found in the tool kit. When replacing the tire the inner tube can be inflated enough to be sure it is not nipping anywhere and then forced on the wheel. Nickel plated and case hardened, it weighs 2½ oz. Mailed prepaid in U. S. on receipt of 65c. (Money Order, N.Y. or Boston Draft). No stamps.

THE AUTOMOBILE POCKETBOOK. By E. W. Roberts, M.E. This is a very complete little book, dealing with the automobile in its modern forms. It was written by a practical man for practical men, and contains a great deal of valuable information. The style in which the Automobile Pocketbook is written is concise and to the point, there being no unnecessary verbiage, so that although small in size, the volume will be much appreciated by those looking for real practical information. It is one of the best pocketbooks. Size, 3½ inches by 4¼ inches. The book contains 319 pages, many interesting illustrations, and is carefully indexed. Bound in leather. Charges prepaid, $1.50. Address THE AUTOMOBILE, 231-241 W. 39th St., New York.

EQUIP YOUR CAR with

STAR TIRE AND TOOL CASE

A distinct departure from the ordinary unreliable tire case—and the "last word" in improvement.
This case is made of thin but rigid steel—is waterproof, dust-proof and cannot be broken into by thieves.
Compact, solidly constructed and will not rattle.
Carries spare shoes, tubes, small tools and spare parts.
Price F. O. B. at factory, $25. Get catalogue 8.

Repair Inner Tubes With Ease and Speed

The Goodyear Self-Cure Repair Outfit offers the easiest, quickest and surest method of repairing inner-tubes. Simply clean the surface of the tube. Wash the raw gum surface of the Self-Cure Patch and stick it on. It sticks tight. The heat generated by friction within the tire vulcanizes the raw gum to a certain extent. Another good, tight-sticking patch is the White Seal Inner Tube Patch. Permanent repairs by vulcanizing by the acid process is the mission of our Acid-Cure Repair Outfit. Quick, permanent repairs can easily be made. Another convenient repair outfit is our No. 2 Outfit. This is used for repairing punctured tubes. Our No. 5 Outfit is of equal efficiency and convenience.

AN ANNOUNCEMENT

Owing to the inability of the APPLE ELECTRIC COMPANY to secure suitable space for their exhibit at the New York Automobile Shows, they will display their line at their New York store, No. 20 Vesey Street. All visitors will be cordially welcomed there.

In addition to the complete line of Aplco Automobile Electric Lighting Systems, Lamps, Fixtures, etc.,

THE NEW APLCO ELECTRIC SELF-STARTER

will have its first public demonstration. It starts your engine. Lights your car. Furnishes current for ignition and signals. Can be seen in action on Inter-State cars.

THE GOLDEN GLOW LENS MIRROR

The biggest feature ever added to an automobile lamp will be shown exclusively on Aplco Electric Headlights.
Aplco Electric Lighting Systems can be seen installed on Speedwell cars.
Don't forget the place—20 Vesey Street, New York City, during the Garden and Palace Shows. Our space at the Chicago Coliseum, No. 98. Boston, Mechanics Hall, 514 Dept. F.

Ford Model T Delivery Car

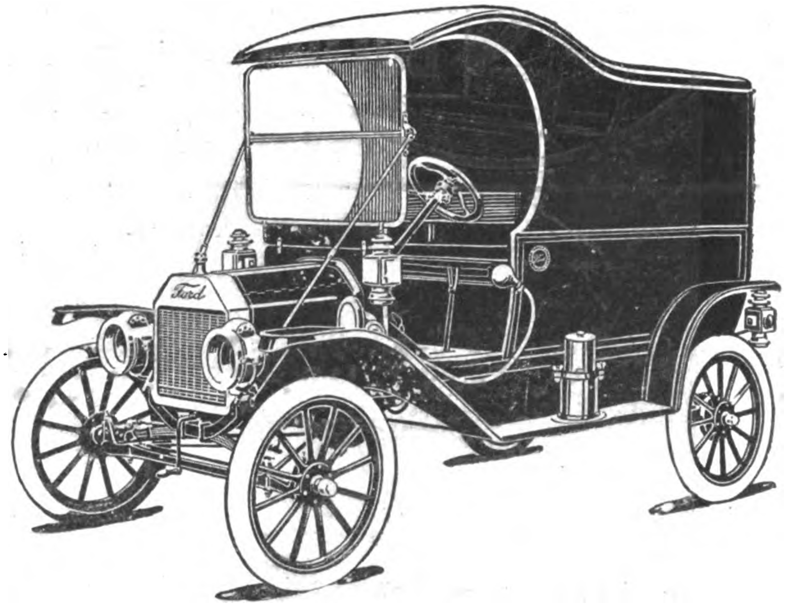
By reason of established efficiency this Delivery Car fits into the wants of business like the telephone. It extends your business. It is simple in design and strong in mechanical construction. Cheap in operation—a glutton for work—and sold at a price that has created an almost universal demand.

$700

Fully Equipped ***F. O. B. Detroit***

This price includes full equipment—Automatic Brass Wind Shield, Speedometer, Ford Magneto built into the motor, two six-inch Gas Lamps and Generator, three Oil Lamps, Horn and Tools. No Ford Cars sold unequipped.

Capacity of this Universal Delivery Car is 750 pounds of merchandise.



We did not offer Ford Model T Delivery Car to the business world until we had thoroughly tried it out in the very line of work that business makes for a Delivery Car. Now—after two years of experience in delivering merchandise—two years over city streets of all sorts—over country roads—in hilly territory in all sorts of weather—winter and summer—we know this car will "deliver the goods." We therefore recommend Ford Model T Delivery Car with our broadest warranty as a dependable, economical, durable, convenient, money-saving delivery car—for the big store, for the little store—for the city, town, village, or country.

The purchase price is low, and the maintenance—from facts established during continuous service—about **five cents per mile.**

At present we can make immediate delivery, but the way orders are coming in prompts the suggestion that you place your order without delay.

Ford Model T Delivery Car has the same Vanadium Steel Chassis which has made Ford cars so practically useful and popular the world over. It has a handsome pressed steel body with a merchandise carrying capacity of 750 pounds.

Four thousand Ford dealers scattered all over the country will give your order prompt attention!

Fixed Prices on Quantity Orders For Ford Motor Cars for Commercial Purposes

To concerns who purchase Ford Cars in quantity lots for Commercial Purposes we will give the benefit of a rate reduction or discount—we have fixed a sliding scale of prices which will be submitted on request. Catalogs and detailed descriptive literature will be mailed gratis. Branch Houses and Large Distributors in all Principal Cities—Dealers Everywhere.

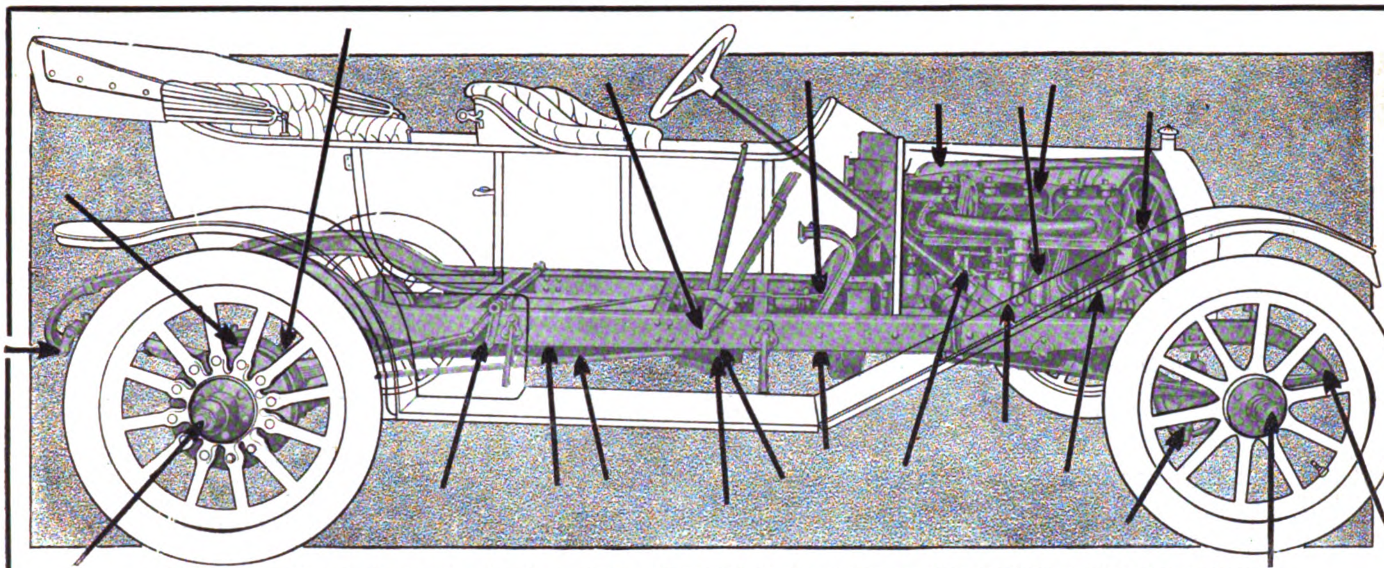
NEW YROK BRANCH 136 W. 52nd St. DETROIT BRANCH: 1191 Woodward Ave. CHICAGO BRANCH: 436 So. Dearborn St.



This illustration indicates the location of the oiling points of a motor car (the number and location of these points vary in different types of cars). Unless properly lubricated an automobile will give trouble and soon wear out.

"Spare the Oil and Spoil the Car"

PENNIES saved on oil or grease may mean dollars spent in up-keep—not to mention annoying delays or the shortened life of your car.

For motorists who recognize the economy of using the best oil we have produced Polarine.

It is not a low-priced oil. But in the long run it will prove sound economy.

Polarine Oil goes through special processes of distillation, pressing and reducing. It is then carefully cleaned and filtered to remove impurities and free carbon. This secures the correct lubricating qualities for gas engine use.

Polarine leaves no appreciable carbon deposit.

Its consistency or "body" is not materially affected by either high or low temperatures. It flows freely down to zero.

Polarine Oil. For all types of gasoline engines. Delivered in sealed cans —five-gallon, gallon and half-gallon sizes.

Polarine Transmission Lubricants. Prepared in three consistencies, "A," "B," "BB." The cans are of convenient size.

Polarine

The Polarine Brand covers:

Polarine Oil (in five gallon, gallon and half-gallon sealed cans), ***Polarine Transmission Lubricants, Polarine Fibre Grease and Polarine Cup Grease.***

These lubricants cover the needs of every part of the car.

Send to our nearest agency for "Polarine Pointers," which include hints on the care of motor cars.

Polarine Fibre Grease, Polarine Cup Grease. Delivered in round cans.

More information in our booklet. Send for it.

Standard Oil Company

GMC

MODEL K
CAPACITY 5 TONS
PRICE, CHASSIS ONLY,
$4400

This truck is one unit of

A Fifty-Ton Equipment

James Butler, Inc., the big New York chain store grocery house has ten trucks of this model, purchased in five orders over a period extending from January, 1910, to September, 1911. The oldest (shown above) and the newest are daily working side by side. So successful have these trucks proven that this concern recently placed on sale their entire remaining stable of heavy draft horses, 100 of them, for the purpose of replacing all with GMC trucks. The first purchase was this one truck; it has sold all the rest.

The best proof of the reliability, efficiency and economy of GMC trucks is in the fact of such repeat orders as this. The GMC line comprises both gasoline and electric trucks in capacities from 1,000 lbs. to 6 tons.

As a result of this complete line, this Company is in a position to recommend and supply the kind of truck best adapted to any given delivery or hauling requirement, without bias toward either gasoline or electric power or toward any one special type of construction.

GMC gasoline trucks are made in both standard types — the lighter capacities with motor under the hood and the heavy-duty trucks with motor under the seat. We are prepared to handle your delivery problems in a comprehensive instead of a fragmentary way, supplying complete installments of delivery trucks, which, although possibly comprising several types, will be standardized under the one GMC mark. It is only with such a standardized system of delivery that the maximum efficiency and economy are possible, to say nothing of the advantages of dealing with a single manufacturer, with a single center of responsibility and service.

GMC Gasoline and Electric Trucks will be exhibited at the New York, Chicago and Boston Shows.

Correspondence from prospective purchasers and dealers is invited.

COMPLETE SERVICE

RIMS 1912

TYPE No. 1

TYPE No. 2

TYPE No. 3

From the inception of the automobile industry, buyers of rims (including manufacturers as well as consumers) have looked upon us as an authority on this subject and await our annual announcement before placing orders. Because of this anticipation, and reliance in our statements, we make the following announcement:

ONE or another of the three types of Standard Universal Quick Detachable Demountable Rims shown on this page has been chosen by nearly every automobile manufacturer as STANDARD equipment for his 1912 car. These rims will fit ANY make of domestic automobile tire, either STRAIGHT SIDE or CLINCHER.

Type No. 3 you are familiar with and present indications are that it will be as popular during the coming year as it was in the past.

Types Nos. 1 and 2, which so quickly climbed into favor with the trade, are, from indications of orders received, going to remain in their present high position. The same felloe band is used on Types Nos. 1 and 2 and will accommodate the rim base or outer rim of either type The side rings are reversible, accepting either straight side or clincher tires. The locking bolts used in the demounting feature are truly the most wonderful device employed for this purpose, a few turns securely fastening the rim into position.

To summarize, all three types are HIGHLY perfected and hundreds of sets are being shipped DAILY to ALL parts of the WORLD and giving SATISFACTION wherever used.

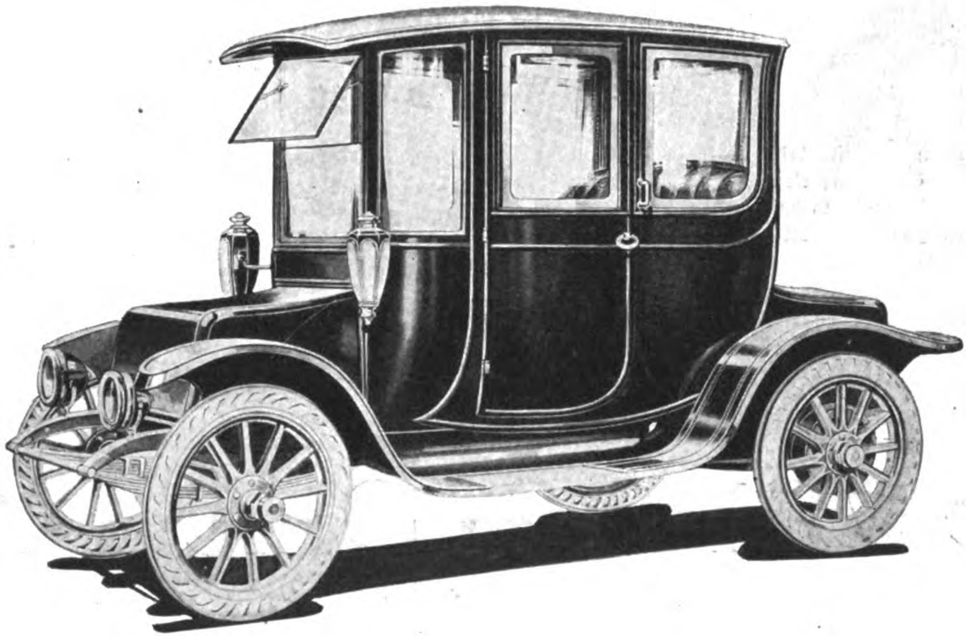
We shall have all three designs on exhibition at Madison Square Garden, New York, January 6th to 20th and at the Coliseum, Chicago, January 27th to February 10th. Your inspection of them we shall consider a great favor and you will be IMPRESSED by their PERFECT construction and HIGH efficiency.

Note—We shall reserve a *limited* number of our 1912 Show Booklets for those unable to attend either show. Postal request or your business card will secure a copy. *It is worth while.*

THE STANDARD WELDING COMPANY

CLEVELAND

NEW YORK
CHICAGO
DETROIT



WHEREVER you may be located, Mr. Dealer, the Detroit Electric will make good. This is the car that is so popular in such hilly cities as Kansas and Seattle. Whatever the conditions in your city, you can recommend this car with absolute assurance that it will satisfy your customers and sell more cars for you.

The Detroit Electric has many exclusive and patented features that cannot be obtained elsewhere, but, what is more to the point, they are features that the public is fast learning to appreciate and are going to demand in an electric vehicle more and more. For instance, those who really know about electric cars are insisting upon a real Shaft Driven car. They will not be satisfied with merely a Shaft Drive with concealed chains at the motor. They want the "Shaft-Drive" "Chainless." Please note the word "Chainless." It means the entire absence of chains or gear reductions at the motor. You cannot obtain this drive except in a Detroit Electric.

The reason we have produced an exclusive Shaft Drive is because of the original type of motor we have developed to meet the peculiar requirements of an electric car. We do not use "stock" motors because they are not speeded and designed to fit the conditions surrounding the electric pleasure car. There are a dozen other features that you should know about that space does not permit mentioning.

THE Detroit ELECTRIC
Shaft Drive
Chainless

Our new catalog, which, by the way, you must see to appreciate, will give you a better idea of this remarkable car. We will gladly send it on request.

We will exhibit at Madison Square Garden Jan. 7th to 13th, Chicago Feb. 2d to 9th.

and

F & S Ball Bearings

A man hath joy by the answer of his mouth: and a word spoken in due season, how good is it!—*Proverbs xv: 23.*

For over fifteeen years the world-renowned house of Fichtel & Sachs, of Schweinfurt, a/M., Germany, the makers of the famous F. & S. Ball Bearings, by virtue of their fundamental patents in all countries, their own inventions, and those acquired from other original sources, have occupied the premier position in the ball bearing industry. This supremacy has been unquestioned because of not only the high quality, but also because of their quantity production of fifteen thousand complete ball bearings daily for various purposes, besides which, their allied ball making plant produces millions of chrome steel balls daily, the two plants employing over thirty-five hundred work-people.

Meanwhile the J. S. Bretz Company, their sole American Representatives, have not been unmindful of the high standing and dignity of the great German concern, and in all their ball bearing literature, advertising, publicity and selling campaigns have adhered strictly to ideal, high-minded, safe and sane methods of doing business. That this course was founded on correct principles is evidenced by the constant growth and volume of our business, the mechanical popularity of the bearing, and our financial success and prosperity from a humble beginning.

A self-appointed public censor of our advertising has in his own heterophemistic way raised a tempest in a teapot over the ball bearings used in the four placed cars in the Vanderbilt Race.

It was Webster who said: "Never mind, your honor, what the plaintiff claims; what say this array of competent witnesses?" Webster's logic applies admirably well to this controversy, doesn't it?

One of the earliest and largest American users of F. & S. Ball Bearings was and is the Lozier Motor Car Company. Almost every notable competitive event won by them, such as road races, hill climbs, gasoline efficiency trials, speedway races, twenty-four hour races, etc., etc., was done on cars equipped with F. & S. Ball Bearings. Naturally enough we rejoiced with them, their agents, and the Lozier car users over these victories. We advertised these many wins, sometimes by means of signed testimonials from the Lozier Motor Car Company, the latter of which attributed the success of the Lozier cars in these events to the F. & S. Ball Bearings. It is to be noted that we always do all of this with the different makes of cars who use the F. & S. product, not so much for our own personal profit, but to advertise the users of F. & S. Bearings in particular, and to spread the gospel of anti-friction construction in the conservation of power, by that "efficiency which is the ratio between a standard of performance and the actual performance."

If we were fond of Kipling we might quote—"After me cometh a Builder—Tell him, I too have known!" Here follows the whole bearing story of the Vanderbilt Race:

Copy of telegram to
LOZIER MOTOR COMPANY,
Detroit, Michigan. Dec. 16, 1911.

——— raises controversy over our advertisement that F. & S. bearings were used in Lozier Vanderbilt cars—our authority your Mr. Perrin. Kindly wire confirmation stating where our bearings were used, and if other makes, also state what and where. Reply desired by Monday. Yours for fair play.

J. S. BRETZ COMPANY.

Lozier says—"The makers of the F. & S. Bearings are, therefore, correct in stating their bearings were used in this car."

LOZIER MOTOR COMPANY
DETROIT, MICH.

Manufacturing Dept.,
J. S. BRETZ COMPANY,
Times Building, New York, N. Y.

December 16, 1911.

BEARINGS USED IN RACER.

GENTLEMEN—In answer to your telegram relative to the bearings used in car which won the Vanderbilt Cup Race, would

A Card

In re Vanderbilt Race

and

F & S Ball Bearings

(Continued)

state that this car was fitted with —— ——— bearings throughout the entire engine, and also throughout the transmission, with the exception that one small F. & S. bearing was used in transmission on account of its narrow width, and a couple of thrust bearings of the F. & S. make were also used.

The rear axle, however, was fitted with the F. & S. Bearings. This is in accordance with statement I have made both to the —— ——— and F. & S. people. The makers of the F. & S. Bearings are, therefore, correct in stating that their bearings were used in this car as long as they *do not state* they were used *exclusively.* This car happened to have been assembled before we began receiving axles made at our Plattsburgh plant, which axles are fitted with —— ——— bearings.

Yours truly,
JGP D (Signed) J. G. PERRIN,
Copy to —— ——— Mfg. Co. Ch. Engineer.

De Palma's Mercedes had F. & S. Bearings

The famous Mercedes cars, which set the fashion to the world in more ways than one, largely use F. & S. Bearings. Manager J. A. Carples, of the Daimler Import Company, says their Chief Engineer told him recently in Germany that F. & S. Bearings were a standard stock equipment on Mercedes cars—both racing and touring.

Ralph De Palma, the metropolitan favorite who drove the Mercedes which finished second, when asked the question which bearings his car had in it, said, "I drove this great car just as I received it from Germany, and if it had any other bearings in it than F. & S., they were placed in it in Germany, and I invite you to inspect it yourselves. The seals on the hub caps are still unbroken, and I have this to say regarding a change of construction in any car I drive: I consider the master mind who designed these racing cars knows what is best to use, and in view of my public announcement of this idea, no one has ever approached me with a view of making a change."

An examination of the De Palma Mercedes car revealed the fact that this car was equipped with F. & S. bearings, and absolutely so in the wheels, which bearings were in dispute.

Regarding the Mercedes which finished third in the race, which was driven by that dashing young American driver, Spencer Wishart, we have this to say: Although the majority of the bearings used in the car are now of another make, still some F. & S. bearings were used, but not enough to emphasize their use—all of which leads up to the variation in the practice of compound use of ball bearings in cars, and hence the use of ball bearings is sometimes as Herbert Spencer once said, "A combination of heterogeneous changes, simultaneous and successive, in correspondence with external coexistences and sequences."

The F. & S. bearing De Palma Mercedes finished second in both the Vanderbilt and Grand Prix races, and is ready without repairs for another race to-day, while the Wishart Mercedes did not finish in the Grand Prix, and lies dismantled to-day.

And so in summing up the result of the Mercedes ball bearing claims, one is reminded of the following squib: "Faith," said the policeman, examining the broken window, "this is more sayrious thin Oi thought it was! It's broke on both sides!"

A Disclaimer

The following letter from Mr. A. L. Riker, Vice-President and Chief Engineer of the Locomobile Company of America, in reply to a letter of ours asking for information as to what bearings were used in Robertson's Locomobile in the 1908 Vanderbilt Race, prompts us to cheerfully enter a disclaimer here as to the use of our bearings in that car. The statement, however, having been originally made in the hurry of preparing copy for an ad, the writer having in mind at the time the fact that the Locomobile Company, since that time, have been continuous users of F. & S. Bearings.

THE LOCOMOBILE COMPANY OF AMERICA
ENGINEERING DEPARTMENT

J. S. Bretz Company, Bridgeport, Conn., Dec. 21, 1911.
New York City.

Gentlemen—I have your favor of the 20th instant and note contents of same. I would state that the make and type of the anti-friction bearing used in Robertson's winning Locomobile in the 1908 Vanderbilt Cup Race, were the —— ——— annular ball bearings. These ball bearings we used in the wheels, jack shaft bearings and transmission. They also were the American made ball bearings, as they were the same as we used in the Vanderbilt Cup Race of 1906.

Yours very truly,
(Signed) A. L. RIKER,
Vice-President.

This closes this discussion in the trade press as to the results of the bearings used in the Vanderbilt Race as far as we are concerned, our time and thoughts being turned towards the coming New Year, the Shows and other events, and in conclusion, we wish that "Content be ever yours—good health, prosperity, and thought for us who ever seek to serve."

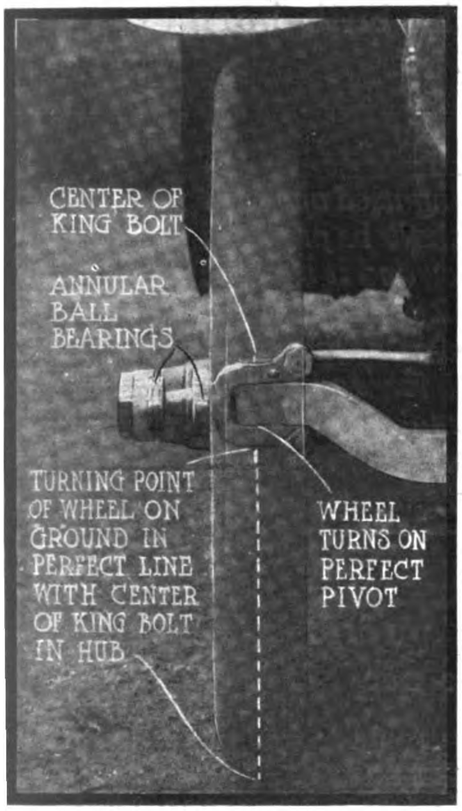
Greatest Safety Device Ever Invented For The Automobile

The B & L Caster Front Axle

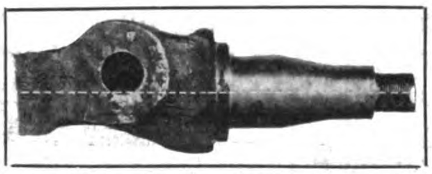
SAFE DRIVING *EASY STEERING* *PERFECT CONTROL*



B & L Caster Front Axle

The advantages of caster steering can easily be seen by contrasting the illustration on the left with the illustration on the right.

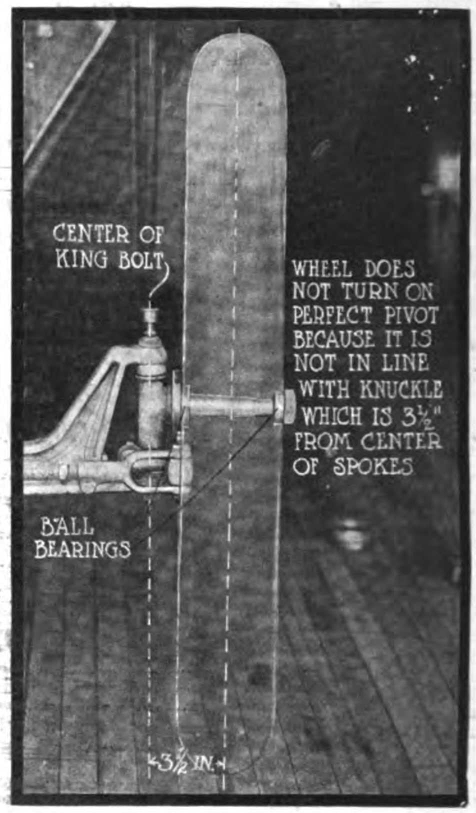
Note how the turning point of The B & L Caster Axle is placed absolutely in the center of the wheel hub. This makes a perfect pivot because the turning point of the wheel on the ground is in perfect line with the center of the king bolt in the hub.



King bolt or turning pin located 3-8 of an inch forward of the center of spindle so as to cause a perfect caster or eccentric front wheel.

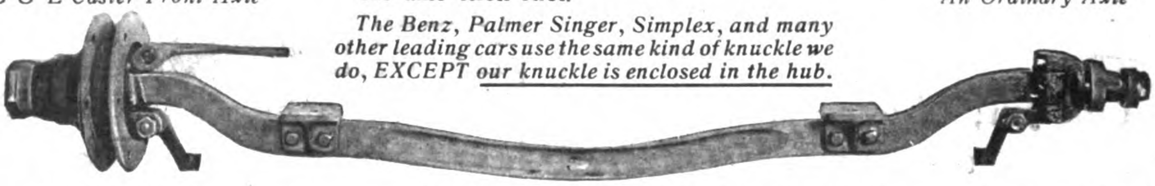
In an ordinary axle the center of the king bolt is 3½ inches outside of the hub and the wheel does not turn on a perfect pivot. The strain on the wheel makes it hard to steer and is often the cause of broken knuckles, which result in serious accidents and loss of life.

A broken knuckle is an impossibility with The B & L Caster Front Axle—strain enough to break it would break the axle itself first.



An Ordinary Axle

The Benz, Palmer Singer, Simplex, and many other leading cars use the same kind of knuckle we do, EXCEPT our knuckle is enclosed in the hub.



When The B & L Caster Front Axle is used the front wheels travel absolutely in the same direction that the back wheels push unless turned purposely by the driver. Steering is so easy as a result of this construction that the steering wheel can be turned with the little finger, and even if the hands are removed altogether the car will continue in a straight course, regardless of road conditions.

Equip your car with The B & L Caster Front Axle and it will possess the following advantages:

Will steer 85% easier—you'll have 90% better control—neither knuckle nor spindle can be broken—car can be turned around in one-quarter less space—front wheels will turn on perfect pivot—control just as easy in sandy or muddy roads as on smooth highway—steering mechanism can become disconnected and car will continue in a straight course, thus allowing plenty of time to stop before an accident occurs—tie rod can be removed, leaving one wheel free, and with control of other wheel car can be guided in any direction—vibration of steering wheel will be eliminated—wheels will roll into and over holes without sidethrust—75% of skidding will be prevented—weight of car will be located on the knuckle instead of being distributed over an outer point of suspension—friction and strain on tires when turning will be eliminated on account of wheels being set perpendicular—bearings will last twice as long because the caster construction eliminates side thrust—you'll enjoy safety in driving you never experienced before.

Let us send you names of manufacturers who will, when requested, equip cars with this axle, which insures Safe Driving, Easy Steering and Perfect Control.

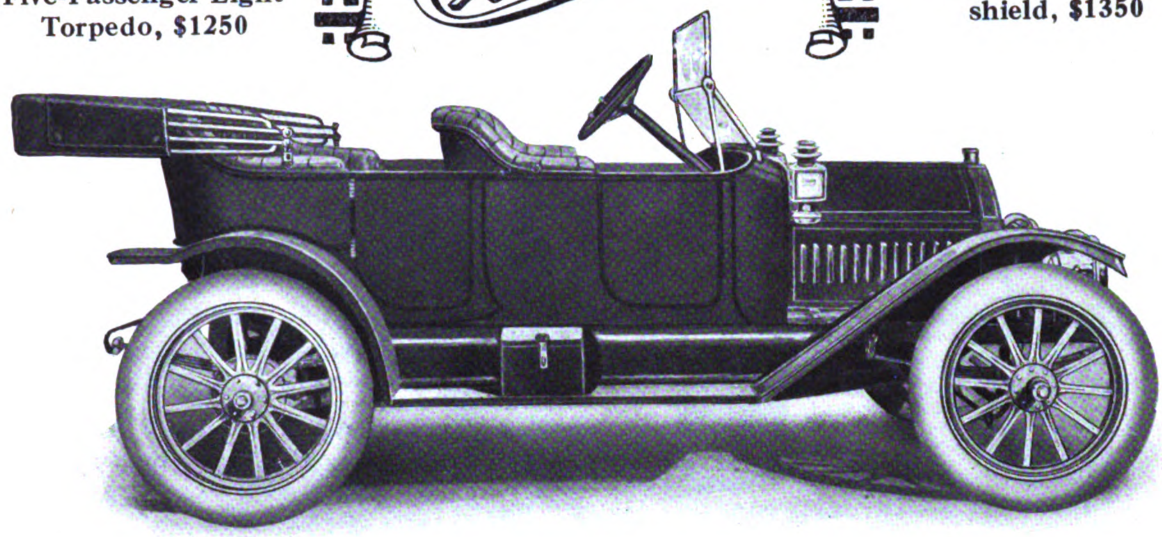
Elmore

Five-Passenger Light Torpedo, $1250

With Top and Windshield, $1350



The One Proven Successful Valveless Motor

Everybody, nowadays, has come to realize the simplicity and super-efficiency of the valveless construction. The whole automobile world is ringing with extravagant claims and arguments for the valveless motors now so widely exploited.

BUT REMEMBER THIS. Every such claim put forth applies with doubled force to the Elmore valveless motor—which, in a dozen years of successful service, has in the hands of owners throughout the country proved both its simplicity and its superiority. We passed the experimental stage years ago.

And the Elmore does not cost $3,000, $4,000, $5,000. There is a model to fit every motoring need, at a price well within the purchasing power of the most conservative.

The Elmore was the Pioneer in Valveless Engine Construction

We have advocated the valveless engine since the inception of the automobile industry in America. The first valveless two-cycle Elmore engine that was installed in a motor-car was a success—a great success. And each year we have refined and simplified it until, in this year's models, we are installing a motor that we believe to be as perfect as human ingenuity can make it. We ask you to prove for yourself that it is the simplest, most efficient automobile engine extant.

In buying an Elmore you are not buying an experiment or a novelty, but a motor tested by thousands of owners for over a dozen years—a motor which, by virtue of patent rights, no other motor-car can have.

Elmore Construction is of the Best

There could be no better built car than the Elmore. Skilled workmanship and careful supervision accompany every detail. We aim to make the car itself a worthy setting for the gem of a motor that runs it.

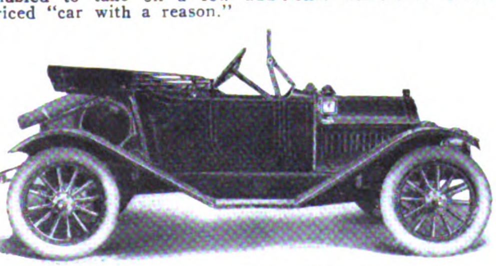
Whether your need be for a roadster or for one of the various types of touring car, you will find an Elmore model which in appearance and in service will rank with any car at any price. And the wonderful, exclusive Elmore motor assures you a smooth, sweet-running car with the utmost in power efficiency, and with an entire absence of valve troubles and valve expense.

Write for the Elmore Book

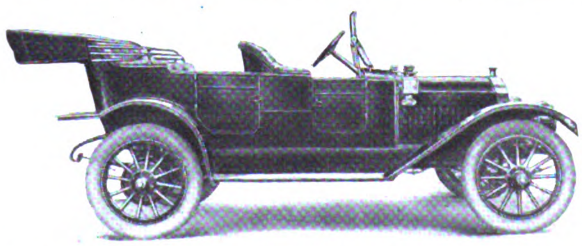
We have prepared a very interesting booklet about the Elmore car, which will be sent free on request, together with the name of the nearest dealer where you can see and test this wonderful car for yourself.

THE ELMORE MANUFACTURING CO., 212 Amanda Street, Clyde, Ohio

DEALERS: For 1912 we have doubled our factory capacity, thus enabling us to double our output. We are, therefore, enabled to take on a few additional dealers in sections not yet allotted. Write us for 1912 proposition on the one moderate-priced "car with a reason."



Torpedo Roadster, $1150, Top and Windshield Extra

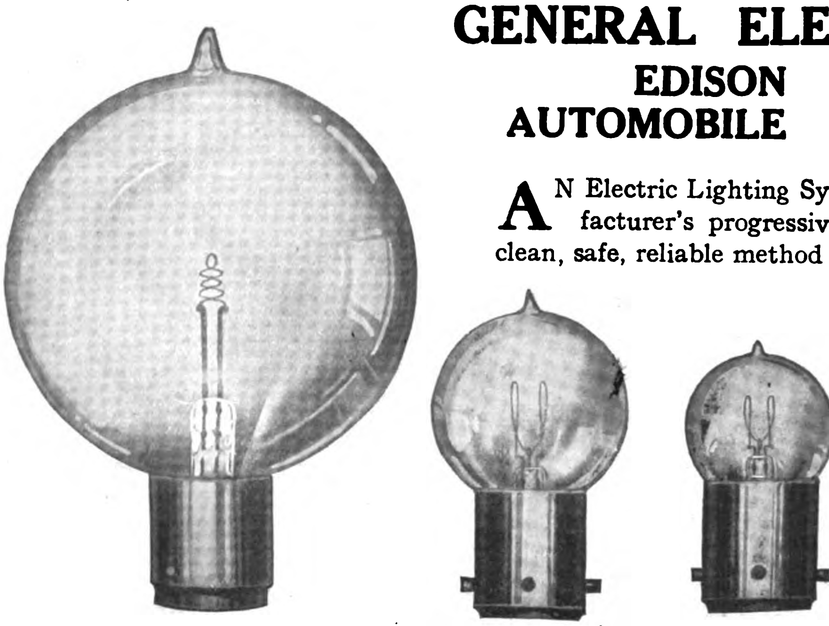


5-Passenger Fore-door Touring Car, $1600, Top and Windshield Extra

GENERAL ELECTRIC COMPANY'S

EDISON AUTOMOBILE MAZDA LAMPS

AN Electric Lighting System on the car is evidence of the manufacturer's progressive policy in supplying the demand for a clean, safe, reliable method of lighting.



Head Side Rear

Electric Lighting needs no attention and any lamp can be operated from the dash.

Edison Mazda Lamps have been carefully designed for automobile service. Note the compact, close-coiled filament of the headlight.

The filaments of Edison Mazda Lamps are made from a drawn wire as strong as piano wire.

Write for Bulletin 4795, which gives some valuable details on automobile lighting. The bulletin tells how simple it is to wire a car for electricity and how existing lamps may be easily converted to electric.
Write for Bulletin today.

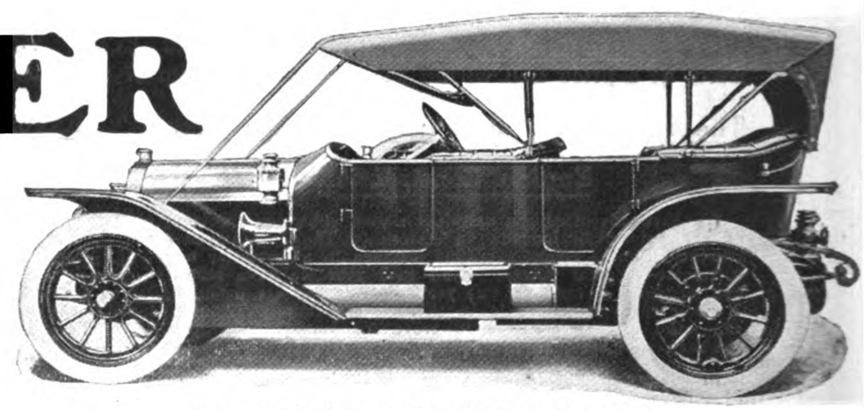
MERCER

The Champion Light Car

In the production of all Mercer models quality is the first aim.



Type 35—Series A and B—Five-passenger or four-passenger torpedo bodies—fully equipped—$2,750.

NEW MERCER SERIES

In your visit to the Automobile Shows, don't fail to give all Mercer models your most rigid inspection. Compare our new type 35, series A and B, foredoor torpedoes, and our raceabouts and runabouts, with the product of any other maker. We honestly believe you will find it hard to get as good a car, and impossible to get a better, at the same price as our new series.

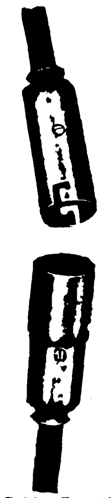
You will find embodied in all Mercer models every up-to-the-minute, thoroughly tried-out, and really meritorious improvement. You will find a car that is strongly built, has power and speed in abundance, has grace of line, is luxurious in appointments and has comfortable riding qualities.

We want you to learn for yourself why the Mercer was able to win such strenuous tests as the Savannah Challenge Trophy Race, the Kane County Stock Championship race at Elgin, Ill., and other notable 1911 speed contests. All-round efficiency made possible the winning of these contests. Every Mercer car turned out possesses efficiency equally as great as our raceabout, which has made a creditable clean-up on both track and road. We can and will prove this.

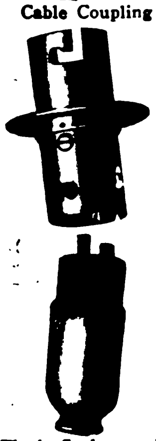
Send for detailed specifications or see us at the shows

MERCER AUTOMOBILE CO., 400 Whitehead Road, TRENTON, N. J.

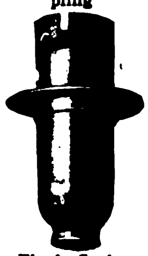
Make Your Car a Convenient Car



Cable Coupling



Flush Socket and Receptacle Coupling



Flush Socket

Two-gang Flush Tumbler Switch

Bayonet Socket Cable Coupling for an electric lighting system. This connector gives close positive contact with absolutely no leakage of current—commendable features where low voltage must of necessity be used. All parts of this coupling are well insulated and in addition to its convenience in making connections the terminals are protected from exposure. The bayonet joint prevents coupling jolting loose.

Flush Socket and Receptacle Coupling. A neat combination for soldering to the base of the lamp. Lighting circuit is broken by the coupling, allowing the lamp casing to be removed if necessary. The oil reservoir may still be retained in the lamp if desired, in addition to the Flush Socket.

Flush Socket and Receptacle Plug. This socket is fitted with a flange similar to the socket above mentioned and can be used in place of it. Instead of a coupling to disconnect or connect circuit, a **Flush Receptacle** and plug is used which can be mounted anywhere on the car. This is an exceptionally useful arrangement for a portable extension light.

All sockets are made to fit our sturdy drawn wire Edison Mazda Lamp.

Switches. Four-gang switches for full electric light equipment, designed to withstand all the conditions of automobile service. Three gang switches just as rigidly constructed, for three or five lamp equipment. Flush or surface type switches built to stand the same hard service, also single pole switches, two-gang switches, etc. No splicing or joints in wiring are necessary with these switches, as all connections are made at back of switch by means of bus bars.

The installation of these "car comforts and conveniences" cannot fail to impress the prospective purchaser in favor of your car.

The Atwater Kent Ignition System

Primary or Secondary Equipment

OWNERS of cars equipped with both magneto and Atwater Kent systems frequently discard the former and use the latter as sole equipment

Owners who begin with the Atwater Kent System never add another. They can imagine nothing more dependable—and they are right.

No source of current is so reliable as a battery. Add the positive, mechanically-driven make and break of the Atwater Kent contact maker, the large, carefully-built A. K. spark coil and the well-insulated A. K. distributor—and you have a combination of elements impossible to surpass for sheer clock-like regularity of action. Yet its very simplicity enables it to be sold at a moderate price.

Use the Atwater-Kent Spark Generator or UNISPARKER as you like—with dry or storage battery, or with a dynamo lighting system. Use it as primary or secondary equipment; it will never play tricks.

Applicable at small cost to most new or old cars.

Booklet gives full technical description.

Akron, Ohio, July 18th, 1910

Atwater Kent Manufacturing Works,
Philadelphia, Pa.

Gentlemen:—

I received the new Unisparker and can say it is certainly giving satisfaction: in fact, I would sooner run on the Unisparker than on the magneto. I think that this is the best system yet, will always believe so providing the Unisparker works as well as it does now.

Yours very truly
(signed) F. C. Millhoff.

Inter-State

The Only Complete Car

Mr. Dealer:
Don't You Want to make these sales?

Buyers will want the Inter-State—the only complete car ever produced! The car that in itself performs **all the labor of Electric Self-Starting, Electric Lighting and Ignition; Tire Pumping; and the Automatic regulation of Fuel Consumption.**

The Labor-Saving Self-Controlled

Inter-State

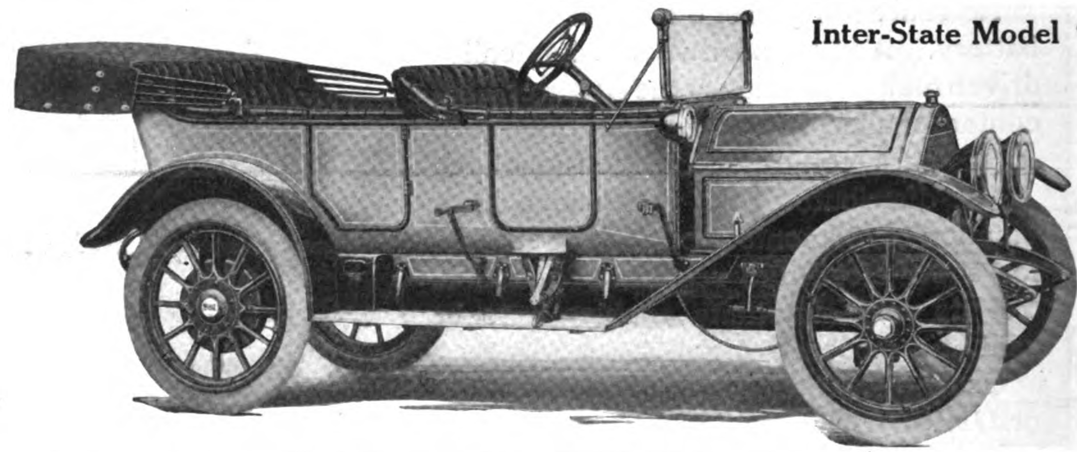
King of all Cars for 1912

Electric Starter "40" and "50" Models — Starts the motor without cranking, without danger, without touching the clutch pedal, without engaging any gears, without releasing a pedal after motor starts. Just push the switch when you are ready to start—nothing more. It's as easy as striking a match.

Electric Lights "40" and "50" Models — Consist of two powerful head lamps with the improved dimming feature. Two dash lamps and a tail lamp. Also the small lamps for illumination of speedometer and clock dials. All or any combination of lights can be turned on by simply turning the switch. Always ready—**no tanks** or generators to look after and renew.

Automatic Carburetor "40" and "50" Models — Entirely regulated from the steering post. A simple movement of the lever by your finger gives all the regulation required for economy of fuel and increased power. Perfect results to novice and expert.

Long Stroke Motor "40" and "50" Models — 4 cylinder type is a triumph of engine making. Made and tested out entirely in the great Inter-State factory. By an ingenious construction all back pressure is avoided and the power "hangs on" at low speed like an electric motor. Enclosed valves make it almost noiseless.



Inter-State Model "40"

Model 40—5 Passenger, Fore Door Touring Car.
Model 41—4 Passenger Demi Tonneau.
Model 42—Roadster type—all with the splendid new en bloc motor, 4½" bore, 5½" stroke, developing 5 to 8 H. P. more than rated, 3 speeds forward and one reverse, completely equipped and with all 1912 features here mentioned.
$2400

Model 50—7 Passenger, Fore Door Touring Car.
Model 51—4 Passenger, Demi Tonneau.
Model 52—Roadster type—all with the new "T" head 5" bore, 6" stroke motor, developing 8 H. P. more than rated by actual test, 4 speeds forward and one reverse, completely equipped and with all 1912 features here mentioned.
$3400

The Inter-State "40" and "50" Equipment is *Complete* High grade top, slip cover, automatic windshield with patented ventilating attachment, a wonderful pair of search head lights; electric side lights; combination tail light; heavy nickel and enamel finish throughout, dimming device on headlights for use on city streets at night; speedometer, clock and electric light combined; signal horn; air adjustment of fuel mixture on steering column; commodious leather flap pockets on inside of doors; cocoa mat; extra demountable rim, gasoline gauge on dash; power tire pump and complete tool outfit.

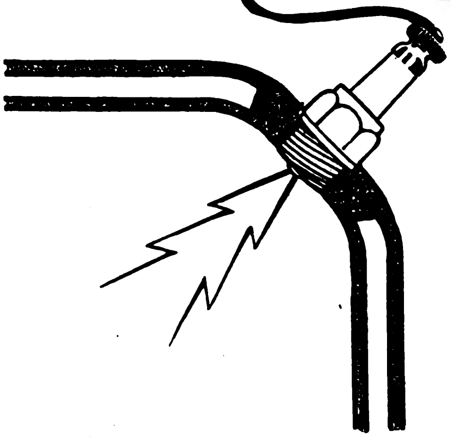
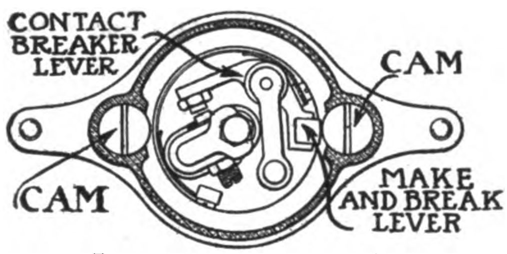
A Hot, Fat Spark to the Centre



Using a separate contact breaker for both battery and magneto—equipped with the very latest Eisemann pole pieces—carrying our most advanced type of breaker boxes—perfectly accessible in all its parts—using nothing but the finest India amber mica as the insulating medium in the condenser; the "type E. M." Eisemann high tension dual ignition system is unquestionably the greatest dollar for dollar ignition system on the market. It possesses all of the exclusive points of Eisemann excellence both as to material used and manufacturing methods employed, and yet is sold at comparatively a low price.

This type E.M. dual ignition magneto consists of the E.M. direct high-tension magneto and a spark coil and switch. The coil is used only in connection with the battery. In this system great care has been taken to use only such parts in common for both battery and magneto as are not subject to accident or wear.

The vulnerable parts, such as the circuit boxes, as mentioned above, are applied individually for each circuit. Particular attention is called to the breaker box details as illustrated in the accompanying cut. Instead of using long steel pieces riveted onto the sides of the breaker box as the contact cams for making and breaking the circuit, it will be noticed that the Eisemann cams are large, round, steel pins. The use of this shape cam, rather than the other types, provides absolute accuracy in the correct making and breaking of the circuit exactly on 180 degrees revolution. This is true because the cam is in contact with the circuit breaking lever the smallest possible length of time and at the very smallest possible point.



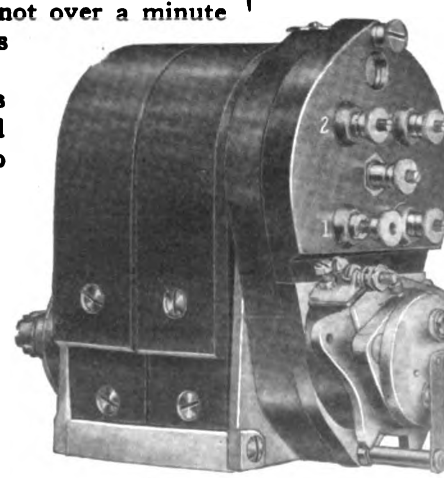
EISEMANN BREAKER BOX

Inasmuch as the fibre piece on the breaker lever is in contact with this cam for the shortest possible time and in the smallest possible measure, there is much less wear and tear on both parts than if the circuit breaking lever were rolling over the long cam for a considerable space of time. The entire breaker box is very strong and sturdy and as near fool-proof as is possible to be constructed.

In order to provide lubrication for the fibre piece on the contact lever, a small oil wick is placed in a slot in the bottom of the circuit breaker, one end of which is in contact with the oil, which seeps out of the ball bearings. Once every revolution of the armature the contact lever laps over this small wick, thereby being both lubricated and cleaned.

The E.M. magneto may be entirely overlooked by the most inexpert person in not over a minute as every part is accessible.

Both breakers may be inspected while the magneto is in operation.

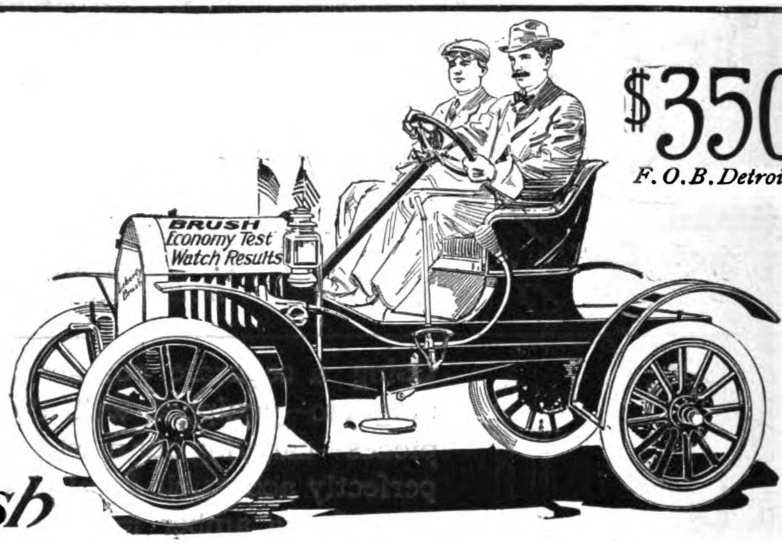


THE EISEMANN MAGNETO CO.

225-227 WEST 57th ST., NEW YORK

527-528 FORD BUILDING, DETROIT, MICH.

100 miles for 39¢



$350
F. O. B. Detroit

in this

Liberty-Brush

This is cheaper transportation than horse, trolley or train

ONE Brush car covered 100 miles at a cost of 39 cents in an economy contest.

108 other cars competed and the average cost was only 65 9/10 cents for the distance.

These cars ran in 109 different cities—so they covered all sorts of roads under all sorts of conditions.

98 cars ran the distance for less than one dollar—less than one cent a mile.

One car ran 48.4 miles on a gallon of gasolene. Two others did more than 40 miles—a dozen made over 30 miles.

One ran 100 miles on a gill of oil—or 3200 on a gallon.

The poorest record was phenomenally good—100 miles for $1.30. No other known means of transportation is so economical—it is cheaper than a horse, trolley or train. It is swifter than a horse, more reliable than a trolley, more flexible than a train—you're not compelled to go only where steel rails lead.

Thousands are using the Liberty-Brush effectively in their business, not only for its economy of time and money, but because it makes more work possible, enables one to earn more money.

Write for data how others are using the Brush for pleasure and business.

Come, see the car—ride in it—learn what it can do. You'll wonder how such on automobile can be built for $350. It couldn't be, except through the United States Motor Company facilities and economies.

IN OCEAN TO OCEAN TOUR
12 PREMIER CARS
ESTABLISHED WORLD'S RECORD
OCEAN TO OCEAN
57969
FROM ATLANTIC TO PACIFIC
Twelve ranges of mountains were climbed; seven great rivers crossed; the practically trackless wastes of Colorado, Wyoming, Utah and Nevada, the great American deserts, hundreds of lifeless miles, yet these bankers, professional men, men of society, manufacturers and merchants, all wealthy Premier owners, did not hesitate to enter these wastes with their wives and families. No greater evidence of confidence in a motor car has ever been given, and they knew, because their cars had seen from three months to three years' service. The twelve Premiers that started finished on the minute on a pre-arranged schedule without mechanical trouble. A wonderful demonstration of Premier consistency. But what does it mean to you? It shows the remarkable easy-riding qualities of Premier. If this had not been perfection, it would have been impossible to have motored forty luxury loving people, ten of whom were women, across this great American continent. Gasoline consumption averaged 12½ miles to the gallon. Four of the 1911 Premiers finished on the original tires. The theory of design, the quality of material, and the high grade of workmanship of the Premier car was established absolutely. These owner drivers had among them owned and driven practically all of the high grade automobiles, some of them the foreign cars. Therefore, the unanimous opinion that there is no car built that could have stood the awful drubbing these Premier cars received in this tour from ocean to ocean is expert testimony. These Premiers are now meeting the day to-day requirements of their owners as they have always done. The ocean-to-ocean tour had no material effect on these Premiers For the ten years in which Premiers have been built, not a year has passed that the manufacturers have not given some wonderful demonstration of the reliability and the consistent performance of Premiers Every year they have been successful in disposing of their output months before the end of the season. It is these things which make Premier the logical car to buy when high grade cars are considered. But more wonderful than all is the fact that eighty-five per cent. of the entire Premier output is still driven by the original owners.
PREMIER Motor Mfg. Co. Indianapolis, Ind.
A portfolio containing 108 illustrations similar to those above which show the 12 Premier Motor Cars in the Rocky Mountains, in the center of the Great American Desert and on the Sierra Slopes will be sent free upon request to Premier Motor Mfg. Co , Indianapolis, Ind.

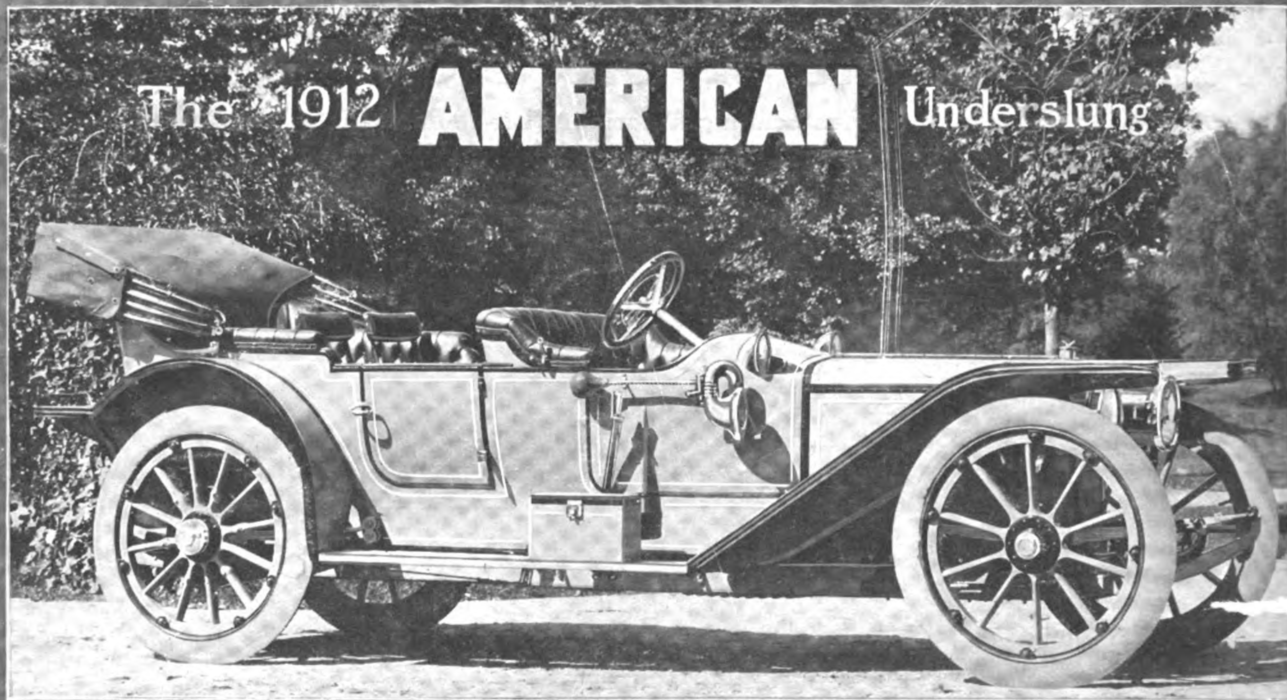
WORCESTER, MASS.



The "American Traveler Special" (Type 56), (shown above) $4500

Six passengers. Wheelbase 140 in.; tires 41 x 4½ in. front and rear on demountable rims. Springs front, 40 inches, rear, 54 inches. Two auxiliary seats in the tonneau. Regular equipment includes top and top boot; 5 lamps, side and tail lights electric, supplied by battery separate from ignition battery; Prest-O-Lite tank; Bosch magneto and storage battery; two extra rims; shock absorbers; foot rest; tire holders; horn; jack, tools and tire repair outfit.

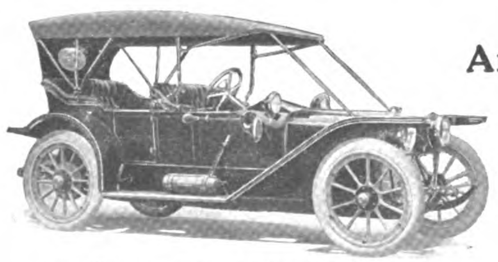
The "American Traveler" (Type 54), $4250

Four passengers; Same chassis as Type 56. Wheelbase, 124 inches. Tire 40 x 4 inches, front; 41 x 4½ inches, rear, on demountable rims. Regular equipment includes top and top boot; 5 lamps, side and tail lights electric, supplied by battery separate from ignition battery; Prest-O-Lite tank; Bosch magneto and storage battery; two extra rims; shock absorbers; foot rest; tire holders; horn; sack; tools and tire repair outfit.

"A Car for Discriminating Buyers"

WE began building Underslung automobiles seven years ago—firm in the conviction that the public would readily see, and appreciate, its many advantages. We have not been disappointed in the result, nor has the public. ¶ To-day there are no less than fourteen manufacturers who have adopted the Underslung idea, although the "American" is still the *one* Underslung car that is designed as such from beginning to end. ¶ It is seldom that foreign critics comment on anything of merit which has originated on this side, therefore, the following item from an English trade paper, and written by a prominent automobile engineer, is *most* significant. ¶ "It is interesting to watch motor car development in America, where many of the best makes find so ready a market that they are never heard of here. Thus an Indianapolis firm, The American Motors Company, is building cars of the Underslung design, which I tried two years ago in Paris and commented on very favorably. The illustration shows how beautifully low the car can be built without reducing the clearance. The frame is simply inverted and hangs from the axles instead of being superimposed. The side members are, therefore, in line with the bottom of the undershield, and if a wheel should, for any reason, break or be thrown, the car would slide harmlessly along like a sledge on its runners.

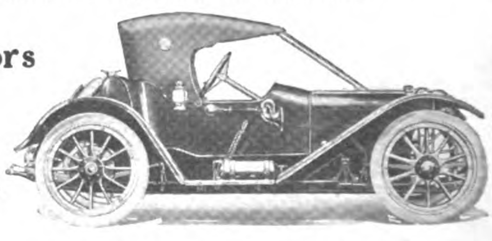
¶ "Another advantage is that the rebound of the springs on the road acts upward instead of downward, so that the effect of a bad bump is merely to cause a slight sinking instead of a violent jerk. Of course, this arrangement makes a car more stable; in fact, it is almost impossible to overturn it. Larger wheels can be used, thus giving easier running and less tire wear. I have long since proved that low seats are a great advantage, and a low built four-seated body on this chassis looks very well and will provide ideal comfort. I hope one of our leading makers will take up this idea, as it does not involve much alteration of existing designs." ¶ There are a great many advantages of Underslung construction not commented upon in the above article. It is a fact, well understood, and acknowledged in automobile engineering circles, that underslung construction is absolutely ideal. We have just issued a book, which covers the matter thoroughly, and at the same time goes carefully into the designing and construction of all "American" Models, showing good pictures of Underslung cars made by us; complete specifications, prices, etc. ¶ We would be glad, indeed, to mail a copy of it to any one who is contemplating the purchase of any kind of an automobile.



The "American Tourist" (Type 34), $2250

Four passengers; wheelbase 118 inches; tires 37 x 4 front and rear on Q. D. demountable rims. Regular equipment includes top and top boot; 5 lamps, dash lights electric; Prest-O-Lite tank; Bosch magneto and storage battery; one extra rim; shock absorbers; foot rest; tire holders; horn; jack; tools and tire repair outfit.

American Motors Company
Dept. D
Indianapolis, Ind.
U. S. A.



The "American Scout" (Type 22), $1250

Strictly a two-passenger car. Wheelbase 102 inches; tires 36 x 3½ inches front and rear on Q. D. demountable rims. Regular equipment includes top and top boot; 5 lamps; Prest-O Lite tank; Bosch high tension magneto; tire holders; horn; jack; tools and tire repair outfit.

We offer to bona fide dealers the fairest sales agreement ever written
